initial increases in overall DA concentration, as determined by our FSCV studies, were chosen (i.v.; morphine, 0.5mg/kg; oxycodone, 0.5 mg/kg). When DA measurements were analyzed with similar time averaging, the results from fast microdialysis were consistent with FSCV findings in that oxycodone elicits a rapid, long-lasting increase in DA, whereas morphine increases dopamine concentration briefly before returning to basal levels. The longer term microdialysis recording also revealed a second peak in DA concentration ~ 20 to 40 minutes post-infusion. Currently we are using FSCV to measure for a longer period of time post-morphine infusion to determine if we can detect the second DA peak revealed by microdialysis. Further, the LC-MS technology used to analyze dialysates allows analysis of additional neurochemicals that are currently being analyzed. Thus, converging evidence from two in vivo recording techniques with fast temporal resolution have revealed previously unresolved changes in DA transmission dynamics caused by morphine and demonstrates that complementary in vivo technology can powerfully address novel characterization of neurotransmission dynamics.

Title: *In vitro* identification of carbon-fiber micro-electrodes with sensitivity sufficient for voltammetric detection of dopamine transients *in vivo*

Authors: *B. E. COUTURIER, C. M. VANDER WEELE, B. T. SAUNDERS, B. J. ARAGONA
Psychology, Univ. of Michigan, Ann Arbor, MI

Abstract: Fast-scan cyclic voltammetry (FSCV) utilizes carbon-fiber micro-electrodes to measure phasic changes in dopamine (DA) concentration in freely moving animals. In traditional FSCV experiments, phasic DA release has been evoked by electrical stimulation or, more recently, by presentation of rewards or reward predictive cues. Advances in this technology have now made it possible to detect naturally occurring changes in DA concentration in freely moving animals that have no obvious environmental cause. We refer to these surges in DA concentration as DA ‘transients’. Among the important aspects of detecting DA transients is that when one

uses an electrode sensitive enough to detect transients during the baseline recording period of an experiment, higher quality, more reliable data are collected. One technical difficulty currently in the FSCV field is that there is no standard in vitro method to quantify an electrode's sensitivity that will predict its ability to measure in vivo transients. Electrodes that detect signals with an equal signal to noise ratio in response to DA concentrations within the 1μM range (either in vitro or in vivo) are not always capable of detecting DA transients during in vivo recordings, which have an average concentration value of approximately 40 nM. Therefore, we hypothesize that in vitro pre-calibration of electrodes at low nanomolar concentrations (i.e., within the range of DA transients) will increase the ability to identify electrodes capable of detecting transients in vivo. Our preliminary data show that we can indeed separate electrodes into two sub-populations (based on their flow cell performance) that show equal signal to noise at 1μM DA concentration but differ significantly in these measures at lower DA concentrations. Our next step is to compare how electrodes from these two different populations perform in awake, freely moving rats, to test the hypothesis that electrodes with excellent performance at low concentrations at the pre-calibration stage will perform better in in vivo testing conditions. This will identify a 'performance threshold' at a low DA concentration (e.g., 50 to 150 nM) that will allow us to identify electrodes that are more likely to detect transients in vivo, thus greatly improving the efficiency of FSCV experiments.

Title: Cadherin 13, addiction and related phenotypes: Human studies

Authors: *G. R. UHL, D. WALTHER
Mol. Neurobio. Br., NIH/NIDA, BALTIMORE, MD

Abstract: Cadherin 13 (CDH13) is a glycophosphoinositol-anchored cell adhesion molecule that is expressed by monoaminergic and cholinergic neurons implicated in addictions, in habenula regions implicated in aversive features of addictive substances and in other brain regions implicated in addiction. CDH13-CDH13 recognition can attenuate process outgrowth when

expressing neurons contact other expressing cells. Clusters of nearby single nucleotide polymorphism (SNP) markers are significantly (10-2 > p > 10-8) associated with a) dependence on at least one addictive substance (7 of 8 datasets; p > 10-11) and b) smoking cessation success (5 of 6 datasets; p > 10-8) and c) attention deficit hyperactivity disorder, a major addiction comorbidity that also influences smoking cessation success (Neale et al, 2010). Clusters of significantly-associated SNPs lie in several regions of the CDH13 gene, including its first and seventh introns. We have identified robust expression of CDH13 mRNA in cerebral cortical and hippocampal specimens from human postmortem brains. In initial samples, and in a replication sample, there was association between level of CDH13 expression and haplotypes marked by intron 1 CDH13 SNP markers that reached the margin of statistical significance. Though there were few homozygotes for the minor A allele of rs8056579, for example, there was about a 50% difference in CDH13 mRNA in cerebral cortex between AA and GG homozygotes, with heterozygotes falling intermediate. These data support the validity of mice with altered levels of CDH13 expression (see adjacent abstract) as models for some of the influences of common human CDH13 variants on drug responses relevant to addiction and smoking cessation. Title: Cadherin 13 and cocaine: Mouse studies

Authors: *J. DRGONOVA[1], B. RANSCHT[2], G. R. UHL[1]
[1]Dept Mol Neurobiol, Natl. Inst. Drug Abuse, NIH, BALTIMORE, MD; [2]Sanford-Burnham Med. Res. Inst., La Jolla, CA

Abstract: Data from genome wide association studies support significant roles for variation in the cell adhesion molecule cadherin 13 (CDH13, T-cadherin) in dependence on substances that include psychostimulants (*see Uhl at al. abstract*). CDH13 mRNA is expressed in monoaminergic and cholinergic neurons implicated in actions of stimulants, in habenula regions implicated in aversive features of addictive substances and in other brain regions associated with addiction. We now report significant upregulation of CDH13 in cerebral cortex and hippocampus

of mice sacrificed 24 hours following acute or chronic/challenge cocaine administration. Conditioned place preference (CPP) studies of mice with reduced CDH13 expression reveal their increased sensitivity to the rewarding effects of the drug: enhanced preference for places associated with 5 mg/kg cocaine and reduced preference for places associated with 10 mg/kg cocaine. Strikingly, locomotion induced by 10 mg/kg cocaine doses during conditioning sessions was similar in wildtype and knockout mice, supporting specificity of this effect. Knockout mice were also indistinguishable from wild type mice in performance in water maze mnemonic testing. These data support roles for CDH13 expression in modulating neuronal connections important for the rewarding and, perhaps, aversive actions of cocaine, with selective influences on ascending and descending limbs of the cocaine dose-response relationship.

Title: A single-nucleotide polymorphism (SNP) in the delta-opioid receptor gene, OPRD1, is associated with differences in regional brain volumes in elderly adults

Authors: *F. F. ROUSSOTTE[1], N. JAHANSHAD[2], O. KOHANNIM[2], E. R. SOWELL[3], P. RAJAGOPALAN[2], A. W. TOGA[2], C. R. JACK, Jr[4], M. W. WEINER[5], P. M. THOMPSON[2]
[1]Neurol., UCLA, LOS ANGELES, ; [2]Neurol., UCLA, LOS ANGELES, CA; [3]USC, LOS ANGELES, CA; [4]Diagnos. Radiology, Mayo Clin. and Fndn., Rochester, MN; [5]Medicine, Radiology, and Psychiatry, Univ. of California San Franscisco, San Francisco, CA

Abstract: Introduction
Delta-opioid receptors (DORs) play a key role in the reinforcing properties of drugs of abuse, and polymorphisms in OPRD1 (the gene encoding DORs) have been associated with drug addiction. DORs also play a role in protecting neurons against hypoxic and ischemic stress. Here, we hypothesized that common variants in OPRD1 would be associated with differences in brain structure, particularly in regions relevant to addictive (frontal and limbic lobes) and neurodegenerative (fronto-temporal areas) disorders. We also predicted that genotypes associated

with reduced volumes would predict CSF levels of markers of neurodegeneration.
Methods
738 Caucasian ADNI subjects were scanned with 1.5-Tesla MRI. Tensor-based morphometry was used to map voxelwise volumetric differences. Association p-values were obtained at each voxel for 5 SNPs spanning OPRD1. Sex and age were used as covariates, and p-value maps were corrected for multiple comparisons by controlling the false discovery rate (FDR). In 387 of our subjects, CSF biomarkers of neurodegeneration (total t-tau and the beta amyloid isoform Aβ42) were obtained. We tested how well the top hit (at the rs678849 locus) predicted CSF measures of t-tau and Aβ42 , adjusting for sex and age.
Results
One very common variant (rs678849, C/T, MAF: T=0.462) predicted differences in regional brain volumes. C allele carriers had smaller brain volumes in anterior cingulate, frontal (including right middle and left inferior frontal gyri), temporal (including inferior and middle temporal gyri) and occipital regions. Post hoc analyses revealed trends ($0.05<p<0.10$) for a main effect of genotype on CSF levels of biomarkers associated with neurodegeneration, and a genotype by diagnosis interaction. Therefore, we examined results within diagnosis groups and found a significant main effect of genotype ($p=0.027$) on t-tau / Aβ42 ratio in healthy elderly ($n=105$). Homozygous C allele carriers had higher ratios than participants with at least one T-allele. C homozygotes also showed a trend for higher t-tau levels ($p=0.063$) compared to T-carriers. However, genotype did not predict CSF levels of any biomarker in MCI ($n=182$) or AD ($n=100$) subjects.
Conclusion
This study is the first to report an association between brain structure and an opioid receptor genetic variant. One intronic SNP was broadly associated with regional brain volumes in a large elderly cohort. Carriers of these variants may be of interest in drug trials targeting DORs to treat addictive and degenerative brain disorders. If replicated, this SNP may help predict CSF biomarkers associated with early brain degeneration in the elderly.

Title: Advancing genetic models and tools for translational neuroscience: Comparative functional studies of the mu-opioid receptor

Authors: *E. J. VALLENDER, C. G. SWEENEY, Z. XIE, H. N. PANAS, D. M. PLATT, G. M. MILLER
Harvard Med. School/Neprc, SOUTHBOROUGH, MA

Abstract: Shared functional polymorphisms within populations and across species can be used for improved translational research. A prime example, the mu-opioid receptor is involved in many natural processes including stress response, pleasure, and pain. Mutations have also been associated with opiate and alcohol addictions as well as with responsivity to treatment. Two common and mutually exclusive polymorphisms have been identified in humans, A118G (N40D), found in non-African populations, and C17T (V6A), found in African populations. While A118G has been studied extensively, C17T is much less well understood. Using the endogenous agonist β-endorphin and the exogenous agonist morphine and antagonist naltrexone, we have undertaken direct binding assays using radiolabeled ligands, competition assays, and assays of downstream signaling. The T17 allele behaves in a functionally parallel manner to the G118 allele, conferring significant differences (K_d or EC_{50}) compared to the most common, "wild-type", allele C17/A118. Further, we have discovered common polymorphisms across non-human primate species in addition to C77G (P26R) already identified in rhesus macaques (*Macaca mulatta*): C140T (P47L) in cynomolgus macaques (*M. fascicularis*), G55C (D19H) in vervet monkeys (*Chlorocebus aethiops sabeus*), A111T (L37F) in marmosets (*Callitrhix jacchus*), and C55T (P19S) in squirrel monkeys (*Saimiri boliviensis peruviensis*). Like C77G, these variants may have similar *in vitro* functional effects to the human alleles. In alcohol self-administration studies in rhesus macaques the C77G allele has been shown to have not only a similar affect on alcohol consumption and preference, but also on response to naltrexone in attenuating these alcohol drinking behaviors. From these studies flow several important conclusions. First, subpopulations can harbor functionally equivalent polymorphisms, complicating association studies and having significant implications for minority health issues. Second, non-human primate models of human disease can be designed with shared molecular etiologies, allowing for separation of genetic and environmental factors in complex human association studies and greater translational relevancy in drug development. Third, evolutionary pressures have produced similar phenotypes across species, suggesting a shared genetic response and perhaps elucidating the mechanism by which these organism-environment interactions are

mediated physiologically and molecularly. These studies set the stage for future investigations of shared functional polymorphisms across species as a new genetic tool for translational research.

Title: Serotonin transporter gene variation and compulsive cocaine self-administration in rats

Authors: *J. R. HOMBERG[1], M. VERHEIJ[2], L. NONKES[2], J. LATOUR[2], J. HANISCH[2], L. VENDRUSCOLO[3], S. EDWARDS[3], C. CONTET[3], G. KOOB[3]
[1]Cognitive Neurosci., Donders Inst. For Brain, Cognition and Behaviour, Nijmegen, Netherlands; [2]Donders Inst. for Brain, Cognition, and Behaviour, Nijmegen, Netherlands; [3]The Scripps Res. Inst., La Jolla, CA

Abstract: Individuals
with cocaine addiction show increased negative emotional responses to stress, which is hypothesized to drive continuation of drug use and compulsivity. Because the serotonin transporter (5-HTT) promoter polymorphism in humans is associated with a negative emotional state and increased risk for cocaine dependence, we hypothesized that the serotonergic system may play an important role in negative reinforcement in cocaine dependence and the resulting compulsive cocaine seeking. However, inherited 5-HTT down-regulation may be associated with neurodevelopmental changes beyond increases in serotonin levels. To determine the contribution of serotonin-mediated neurodevelopmental changes *versus* increased serotonin levels to
anxiety and compulsive cocaine seeking, we compared our previously generated 5-HTT knock*out* rats to rats injected
with viral vectors designed to knock*down*
5-HTT in the dorsal raphe nucleus. Specifically, one group of 5-HTT knock*down* and knock*out* rats was tested for anxiety on the elevated plus maze test
under naive conditions. A separate group of 5-HTT knock*down* and knock*out* rats

was allowed to self-administer cocaine under short access (1 h per day) and long access (6 h per day) conditions, as well as under a progressive ratio schedule of reinforcement. 24 h into withdrawal following a short or long-access session these animals were tested for anxiety on the elevated plus maze. We found that both 5-HTT knock*out* and 5-HTT knock*down* rats showed increased anxiety under naive conditions. Furthermore, 5-HTT knock*out* rats self-administered higher amounts of cocaine under both short and long access conditions, whereas 5-HTT knock*down* rats showed an increase in cocaine self-administration only under long access conditions. In addition, 5-HTT knock*out* rats as well as 5-HTT knock*down* rats were more motivated to self-administer cocaine as measured under progressive ratio conditions 24 h after long access to cocaine. Finally, both 5-HTT knock*out* and 5-HTT knock*down* animals showed increased anxiety 24 h into withdrawal. In conclusion, we show that both constitutive 5-HTT knock*out* and adult 5-HTT knock*down* increase anxiety, which may be an important factor driving increased cocaine self-administration. These findings may have heuristic value for the treatment of cocaine dependence, because they suggest that increased serotonin levels, rather than serotonin-mediated neurodevelopmental changes, contribute to increased vulnerability to addiction in individuals with a polymorphism in the serotonin transporter region.

Title: Adenosine transporter ENT1 regulates circadian home-cage activity and ethanol intake in female mice exposed to constant light

Authors: *C. L. RUBY[1], O. A. ABULSEOUD[2], C. A. ADAMS[1], D. L. WALKER[3], M. A. FRYE[2], D.-S. CHOI[1]
[1]Mol. Pharmacol., [2]Psychiatry and Psychology, [3]Psychogenomics Lab., Mayo Clin., Rochester, MN

Abstract: Circadian rhythm disruption is a common feature of mood disorders, addiction, and their frequent comorbid expression, constituting a significant barrier to treatment and a risk factor for relapse. Adenosine signaling has been implicated in alcoholism, mood and anxiety disorders, and circadian rhythm regulation, representing a possible link between them and a promising therapeutic target. Adenosine levels are controlled in part by equilibrative nucleoside transporters (ENTs). Compared to wildtypes, mice lacking ENT1 are less sensitive to ataxia and sedation from acute ethanol, drink more alcohol than wildtypes, and display some behavioral and neurochemical features of mania, including increased risk-taking, reduced behavioral despair, and elevated striatal dopamine levels. Consistently, a genetic variant of ENT1 was associated with mood dysregulation, chronodisruption, and alcoholism in women. However, the specific role of ENT1 in circadian rhythm regulation is unknown. Here, we examined circadian rhythm stability under a normal 12 h light:12 h dark (LD) photocycle in ethanol-naive and ethanol-exposed (2-bottle choice) female ENT1 null and wildtype mice using measures of entrainment, alpha (the duration of the active phase), bout distribution and intensity of activity. Ethanol drinking delayed the activity onset for both genotypes, but ENT1 null mice became active before wildtypes regardless of ethanol exposure. Ethanol reduced alpha only in wildtype mice, while ENT1 null mice were insensitive to this effect. ENT1 null mice showed less intense activity at night (active phase) compared to wildtypes, and ethanol reduced this measure in both genotypes. Interestingly, ethanol exposure affected bout length and intensity differentially between genotypes during the day (rest phase), reducing these measures in wildtypes, but increasing them in ENT1 null mice. As adenosine regulates circadian responses to photic input, we also examined ethanol drinking in the same mice under constant light (LL), which disrupts circadian rhythms and affects drinking behavior. LL lengthened free-running period similarly in both genotypes. However, only ENT1 null mice showed elevated ethanol consumption and preference in LL, with no such effect in wildtypes. Taken together, these data suggest that disruption in ENT1 levels or function may represent a risk factor for chronodisruption-related escalation in alcohol intake, and that this may be related to ethanol-induced stimulation, rather than suppression, of activity during the light-phase.

Title: Signaling pathways targeting human dopamine transporter genes

Authors: *Z. LIN[1], Y. ZHAO[1,2], N. XIONG[1], Y. ZHOU[1], C. CHUNG[1], C. E. GLATT[3], O. ISACSON[1]
[1]McLean Hosp., Belmont, MA; [2]Xinxiang Med. Univ., Xinxiang, China; [3]Cornell Univ., New York, NY

Abstract: Regulation of transcription determines where, when and extents to which a gene is expressed. Dopamine transporters (DATs), the plasma membrane DAT and vesicular monoamine transporter 2 (VMAT2), are the major regulators of dopamine (DA) transmission. The expressions of these transporters are highly circumscribed in discrete regions throughout the brain. Therefore, dissecting the pathways that regulate these transporter genes may help us understand DA-related brain functions (reward, learning and memory, motor function, rest, cognition, hormone production, and sociability), pharmacologic and genetic modulations of these functions and brain disorders (Parkinson's disease, attention deficit hyperactivity disorder, addiction, depression, schizophrenia and bipolar disorder), and develop rational medications. However, little is known about their regulatory pathways. We have used pharmacologic and genetic approaches in various *in vitro* systems to reveal the pathways for the two human transporter genes. We find that both DAT and VMAT2 genes are regulated by cAMP, G protein αs, protein kinase C, PI3 kinase and oxidative stress. There are many more VMAT2-responsive pathways than DAT-responsive ones and most regulations are affected by genetic variations in the genes. These findings compose an emerging picture on transcriptional regulation of the DATs.

Title: Prolonged- and limited-access to cocaine self-administration at various periods of abstinence induces distinct patterns of DNA methylation.

Authors: *K. PLOENSE[1,2], A. CARR[3], T. W. BREDY[4], Y. E. SUN[5], T. E. KIPPIN[2]
[1]Univ. of California Santa Barbara, Simi Valley, CA; [2]Psychological and Brain Sci., [3]Univ. of California Santa Barbara, Santa Barbara, CA; [4]Queensland Brain Institute,, Queensland, Australia; [5]Dept. of Psychiatry and Biobehavioral Sci., Univ. of California Los Angeles, Los Angeles, CA

Abstract: DNA methylation is a key determinant of gene expression and is implicated in neuroplasticity relevant to addiction. Here, we examine DNA methylation within the medial prefrontal cortex (mPFC) following limited- or prolonged-access cocaine self-administration and varying periods of cocaine abstinence. Rats fitted with IV catheters lever pressed for saline, limited-access (1h/ day) to cocaine, or prolonged-access (6h/day) to cocaine for 15 sessions. The rats were then decapitated for tissue collection at 1, 14, and 60 days of abstinence from cocaine self-administration. As reported previously, only prolonged-access rats exhibited escalated cocaine intake across sessions. MeDIP-CHIP analyses of mPFC tissue revealed dramatic and extremely gene-specific changes in DNA methylation/demethylation within promoters across groups. Analyses of peak differences revealed significant learning-induced changes in DNA methylation with 993, 994, 880 genes exhibiting >1 or <-1 peak differences between limited- versus prolonged-access, saline versus limited-access, and saline versus prolonged-access, respectively, with the overall effect of cocaine-seeking appearing to bias towards de-methylation. A number of receptor and related genes involved in PFC neurotransmitter systems implicated in addiction exhibited altered DNA methylation. For example, the Homer2 promoter showed active changes in DNA methylation following prolonged-access but not in other conditions. Sodium bisulphite conversion followed by mass spectrophotometry interrogating a 1000bp sequence of the Homer2 promoter confirmed increased methylation induced by prolonged-access, including CpG sites within putative consensus sequences for GATA-1 and p300 and CRE-BP. These results demonstrate that cocaine self-administration alters DNA methylation, with prolonged-access leading to escalation of cocaine intake, which induces a

pattern of DNA methylation distinct from limited-access. Given the stability of DNA methylation, the present findings provide a possible molecular mechanism mediating the enduring nature of cocaine addiction.

Title: Medial prefrontal cortex afferents to the nucleus accumbens core, but not to the ventral tegmental area, are activated during cue-induced reinstatement of cocaine seeking.

Authors: *E. MCGLINCHEY, S. V. MAHLER, G. ASTON-JONES
Neurosci., Med. Univ. of South Carolina, Charleston, SC

Abstract: Drug addiction is a chronically relapsing disease; relapse often occurs when addicts are exposed to conditioned stimuli that initiate drug seeking behavior. Cues that provoke reinstatement of drug seeking induce Fos expression, a marker of neuronal stimulation, across a variety of reward-related structures including the prefrontal cortex (PFC), nucleus accumbens core (NAcc) and ventral tegmental area (VTA). Kalivas and colleagues have shown that the projection from dorsal PFC (prelimbic cortex, PL) to NAcc is required for reinstatement of extinguished cocaine seeking. In addition, our lab has shown that glutamate in VTA is needed for cued reinstatement of cocaine seeking. However, the specific circuit projections between subregions of PFC to NAcc or VTA that are activated in cue-induced reinstatement have yet to be elucidated. This study used behavioral and anatomical techniques to assess activation of PFC projections to NAcc or VTA during cue-induced reinstatement of cocaine seeking. All animals received jugular catheterizations followed by injections of the retrograde tracer cholera toxin B subunit (CTb), into either NAcc or VTA. These rats were then trained to intravenously self-administer 0.2mg/kg infusions of cocaine paired with a light/tone CS+ cue for 10 days and then extinguished of this behavior for 7+ days. Rats were then subjected to an additional extinction training day or a 2-hour reinstatement test session, in which the light/tone cues were presented

without cocaine infusions. Rats were perfused at the end of either session and brains were removed and processed with dual label immunohistochemistry for CTb and Fos. This allowed us to investigate Fos activation of NAcc- or VTA-projecting PFC neurons. Preliminary results indicate that PL neurons that project to NAcc are Fos-activated during cue-induced reinstatement behavior but not during extinction. This contrasts with PL projections to VTA, which were not activated during reinstatement. In addition, the percentages of NAcc-projecting PL neurons that were Fos activated were correlated with reinstatement behavior in individual animals. No Fos induction was observed for infralimbic cortex neurons that were retrogradely labeled from NAcc or VTA. These results demonstrate differences in Fos activation for projections to NAcc vs. VTA from different PFC subregions, further characterizing the circuits underlying cue-induced relapse in addiction. Title: Selective deficits following long-access methamphetamine self-administration in rats

Authors: *B. M. COX[1], Z. A. COPE[1], A. PARSEGIAN[1], S. B. FLORESCO[2], G. ASTON-JONES[1], R. E. SEE[1]
[1]Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [2]Psychology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Methamphetamine (meth) addiction is a chronically relapsing disorder that produces significant and persisting cognitive deficits. These deficits include decreased cognitive flexibility, which may impair addicts from altering their drug use and ultimately lead to increased relapse to drug seeking. Neuroimaging studies have demonstrated that meth addicts have decreased resting activity in the prefrontal cortex (PFC) that corresponds with decreased cognitive flexibility. Although several set-shifting tasks have been developed to assess cognitive

flexibility in rodents, the automated set shift task (ASST) used in the current study can selectively assess specific cognitive parameters commonly disrupted in human addicts. For example, excitotoxic lesions or reversible inactivation of the medial PFC selectively disrupts extra-dimensional shift (EDS), whereas orbitofrontal cortex (OFC) lesions selectively disrupt reversals. Further, the ASST provides more detailed analysis of these types of errors for more direct comparison and optimal face validity with human studies. Here, we determined whether extended access (6 hr/day) of meth self-administration, as compared to sucrose self-administration controls, would impair performance on the ASST. Although no differences were seen in EDS in rats with a chronic meth history, meth subjects showed increased perseverative errors during task reversal, an effect not seen in sucrose trained rats. These data indicate that long access meth self-administration may disrupt OFC function. Ongoing research will determine relationships between cognitive deficits in this task, meth intake history, and reinstatement to meth seeking within the same subjects.

Title: Decreased response of VTA dopamine neurons to tVTA activation after chronic morphine

Authors: *J. KAUFLING[1], G. ASTON JONES[2]
[1]Dept. of Neurosciences, Med. Univ. of South Carolina, Charleston, SC; [2]medical university of South Carolina, Charleston, SC

Abstract: Evidence indicates that GABAergic (GABA) neurons in the tail of the ventral tegmental area (tVTA), also called rostromedial tegmental nucleus (RMTg), control the mesolimbic dopaminergic (DA) system (Kaufling et al. 2009; Jhou et 2009) and express μ opioid-receptors. Opiates influence the DA system via VTA GABA interneurons, but the tVTA also could be a key player in opiate effects on VTA DA neurons. VTA GABA neurons have been studied extensively, but little is known about the activity of tVTA GABA neurons or their response to morphine (mor) or mor withdrawal.
Using in vivo recording in anaesthetized rats, we compared the activity of the tVTA GABA and

VTA DOPA neuron in response to acute mor, chronic mor (CM), or 14 days of withdrawal from CM (14dw).
Similar to Georges et al. (2006), acute morphine but not 14dw, increased the basal firing of VTA DA cells. Also, iv mor increased the firing rate of VTA DA neurons in naive, but not withdrawn rats. These data suggest a mor tolerance in VTA DA neurons.
These finding are to contrast to those obtained in the tVTA GABA neurons. We show that acute mor in naive rats decreased the firing of tVTA putative GABA neurons. We also found that the basal firing rate of tVTA GABA neurons was markedly lower in CM and 14dw rats than in naive rats. Also, an acute injection of morph in previously morph-exposed rats (CM or 14dw) or a local injection of morph in the tVTA still induced an inhibition of tVTA GABA cells.
In contrast to VTA DA neurons, these data reveal that tVTA GABA neurons do not show tolerance to mor. More interestingly, these results show that CM may induce an apparent functional disconnection between tVTA and VTA.
To further investigate the VTA/tVTA relationship in mor-exposed animals, we expressed a designer receptor (Designer Receptors Specifically Activated by Designer Drugs, DREADD) in tVTA neurons using a viral vector in vivo. This hM4D DREADD, an alternate strategy to optogenetics to control targeted neuronal populations, is a Gi-coupled receptor that inhibits activity selectively of expressing neurons when stimulated by its agonist, clozapine-N-dioxide (CNO). Rats received unilateral injections into tVTA of a lentivirus containing the hM4Di DREADD receptor gene downstream of a synapsin promoter. After recovery, rats were divided in two groups: naïve rats and 14dw rats.
To test VTA/tVTA disconnection, we are using in vivo unit recordings to compare the effect of tVTA inactivation on the firing rate of VTA DA cells by stimulating DREADDs with CNO administration. These studies are ongoing; we hypothesize a stronger activation of VTA DA cells after tVTA GABA neuronal inactivation in naive rats than in 14dw rats.

Title: Just C NO to DREADDs: Inhibition of ventral pallidum projection to VTA blocks cue-triggered cocaine seeking.

Authors: *S. V. MAHLER[1], E. M. VAZEY[1], J. KAUFLING[1], B. L. ROTH[2], G. ASTON-JONES[1]
[1]Neurosciences, Med. Univ. of South Carolina, CHARLESTON, SC; [2]Pharmacol., Univ. of North Carolina, Chapel Hill, NC

Abstract: Designer receptors exclusively activated by designer drugs (DREADDs) are synthetic G-protein coupled receptors that are inert, except in the presence of their agonist, CNO (which is inert in the absence of DREADDs). DREADD-expressing neurons can therefore be experimentally controlled in a highly selective, "lock-and-key" manner.
Although light-activated opsins are preferable for experiments requiring precise temporal (milliseconds to seconds) control of neuronal activity, DREADDs can be preferable when extended periods of inactivation are desired (minutes to hours). In addition, DREADDs do not require tethering of animals to a light source, an advantage when animals perform complex behaviors.
Here, we examined the role of ventral pallidum (VP) and its projection to ventral tegmental area (VTA) in reinstatement of cocaine seeking. We used an hM4D Gi-coupled DREADD construct, expressed under control of a synapsin promoter via lentiviral neurotransduction in vivo in rats. First, we examined the necessity of VP for reinstatement elicited by either cocaine-associated cues or a cocaine priming injection. We bilaterally transfected VP neurons with the DREADD viral vector, trained rats on cocaine self-administration and extinction, and then systemically administered several doses of the DREADD agonist CNO during cue-induced or cocaine primed reinstatement sessions. We found that CNO dose-dependently blocked cue-induced but not cocaine-primed reinstatement of cocaine seeking, indicating that VP activity is required for cues to trigger cocaine seeking.
We previously observed that VP projections to VTA are robustly Fos activated during cue-induced reinstatement behavior, so we next sought to examine whether this specific projection is necessary for cue-induced reinstatement of cocaine seeking. For this, we again bilaterally transfected VP neurons with the hM4D DREADD, allowed time for DREADD transport to axonal terminals in VTA (2-3 weeks), and implanted bilateral cannulae into VTA. Prior to cue-induced or cocaine-primed reinstatement sessions, we microinjected CNO into VTA to specifically inhibit DREADD-expressing VP terminals. Again, this attenuated cue-induced, but not cocaine-primed reinstatement.
These findings demonstrate that i) DREADDs are a useful means of modulating neuronal activity in behavioral experiments, ii) DREADDs can be used to locally inhibit terminals of projections from transduced neurons, and iii) ventral pallidum projections to VTA are crucial for cue-induced, but not cocaine-primed reinstatement. Title: Behavioral economics for the neuroscientist: Demand curve analysis of the within-session threshold procedure

Authors: *B. BENTZLEY, K. FENDER, G. ASTON-JONES
Med. Univ. of SC, Charleston, SC

Abstract: Behavioral-economic demand curve analysis offers several useful measures of drug self-administration not available in typical behavioral analyses. Demand curves are used to mathematically model the consumption of drug as a function of the effort (lever presses) required to obtain a mg of drug. Generation of demand curves with this approach previously required multiple days, with a different fixed-ratio schedule for each day. This was a serious limitation for many neuroscience studies (e.g., local drug microinfusions, unit electrophysiology). However, recent within-session threshold procedures allow demand curve construction from a single 110-min cocaine self-administration session, making this analysis relevant to a broad range of self-administration experiments. There are several useful and important demand analysis parameters; some of these can be approximated via graphical estimation, but a mathematically fit demand curve is required to predict the 'essential value' parameter (α) and to derive accurate estimates of the maximum price (or effort; *Pmax*) subjects are willing to expend for drug. A mathematical approach to demand curve fitting has not been reported for the within-session threshold procedure. *Here,* we provide a method for fitting demand curves to single-session data for cocaine threshold procedure self-administration. Animals were trained to self-administer cocaine, and then tested with the threshold procedure in which the cocaine dose was sequentially decreased in successive 10-min bins during a single FR1 session. Critically, brain cocaine concentrations were estimated based on intake and response rates, and price points outside of stable brain cocaine concentrations were removed before curves were fit. Curve-fit accuracy was determined by the degree of correlation between graphical and calculated parameters for Q_0

(desired brain concentration at null effort) and *Pmax*. Our novel fitting method generated precise estimates of Q_0 and α, and resulted in *Pmax* values with significantly closer agreement with graphical *Pmax* than conventional methods. Our results show that the exponential demand equation can be fit to single-session data using the threshold procedure for cocaine self-administration. This method provides more accurate estimates of *Pmax* than graphical methods, and allows determination of α, permitting a more comprehensive analysis of drug self-administration via a behavioral-economic framework.

Title: Addiction-prone OPRM1 118GG mice demonstrate less preference for naturally rewarding saccharin compared with 118AA mice

Authors: *C. S. FREET, P. S. GRIGSON
Dept Neural & Behav Sci., Penn State Coll Med., HERSHEY, PA

Abstract: Rodents suppress intake of a saccharin conditioned stimulus (CS) when it is paired with a drug of abuse (Cappell et al., 1973; Carey and Goodall, 1974; Goudie et al., 1978). This phenomenon, termed reward comparison, is thought to be mediated by the rewarding properties of the drug and serves as a model for a number of behaviors observed in addiction including anticipation of reward, cue-induced withdrawal, and devaluation of natural rewards (Grigson, 1997, 2000, 2008). OPRM1 A118G is a single nucleotide polymorphism (SNP) of the mu-opioid receptor that has been linked to addiction in human alcoholics and is associated with greater alcohol and drug intake in humans, non-human primates, and mice (Bond et al., 1998; Miller et al., 2004; Ray and Hutchison, 2007; van den Wildenberg et al., 2007; Ramchandani et al., 2010). Similarly, OPRM1 118GG mice exhibit greater avoidance of a cocaine-paired saccharin cue compared to their 118AA wild type counterparts and it is believed that this facilitated effect is due, in part, to less preference for the naturally rewarding saccharin cue. To investigate this possibility, OPRM1 A118G mice (118AA: n=8; 118AG: n=9; 118GG: n=10) were evaluated in a

series of one-bottle and two-bottle intake tests for saccharin (0.02%, 0.15%, 0.30%) as well as the non-gustatory stimulus capsaicin (0.5µm, 1.0µm, 4.0µm). Results demonstrate that, while intake in one-bottle tests were similar between the genotypes for saccharin and capsaicin, intake of 0.15% saccharin against dH_2O in the two-bottle test was significantly greater in 118AA compared with 118GG mice.

Title: Drug-unpaired environments modulate dendritic spine dynamics

Authors: *B. F. SINGER[1], N. BUBULA[2], V. BINDOKAS[3], P. VEZINA[2]
[1]Committee on Neurobiol, [2]Dept. of Psychiatry and Behavioral Neurosci., [3]Dept. of Neurobiology, Pharmacol. and Physiol., Univ. of Chicago, Chicago, IL

Abstract: Repeated exposure to amphetamine leads to the development of biochemical and neuroanatomical phenotypes that may underlie the formation of associative drug conditioning. Brief elevations in c-Fos expression in nucleus accumbens (NAcc) neurons following re-exposure to a drug-paired, but not unpaired, environment suggest that expression of this immediate early gene serves as a marker for neurons which process drug-context information. This correlation is supported by evidence showing that prevention of conditioning inhibits environmental regulation of c-Fos expression. In contrast, ΔFosB displays a long-lasting context-independent increase following repeated drug exposure, a neuronal expression pattern that overlaps with c-Fos activation following exposure to drug-paired stimuli. When conditioning accrues, a proportion of ΔFosB(+) cells may process this information although ΔFosB levels are also increased if conditioning is prevented. This transcription factor may thus have various functions and serve as a marker for cells encoding other information such as non-associative

behavioral sensitization that can manifest in the absence of associative conditioning. Previous research has revealed brain-region specific changes in dendritic architecture following repeated systemic amphetamine administration. Given the well documented relationship between conditioning and dendritic spine growth, we hypothesized that dendritic changes may be restricted to c-Fos(+) and ΔFosB(+) neurons that encode this behavioral information. Labeled cells were injected with the carbocyanine neuronal tracer DiI in order to characterize their dendritic spine morphology. One week after withdrawal from repeated amphetamine, NAcc FosB(+) cells showed an increase in the basal frequency (no challenge) of spines with medium head diameters. This increase was absent in c-Fos(+) neurons 30-minutes after re-exposing rats to a drug-unpaired environment, but preserved after exposure to a drug-paired environment. Consistent with these results, significant decreases in levels of the actin binding proteins Arp2 and p-cofilin were observed following exposure to the drug-unpaired environment. These results support the existence of long-lasting conditioning-related changes in the dendritic spine properties of NAcc neurons following repeated amphetamine and the inhibitory regulation of these changes by drug-unpaired environments.

Title: A nutritional supplement regime diminished addictive behavior and mean arterial pressure without affecting serum catecholamines

Authors: *L. E. YOUNG, A. M. WEBBER-WAUGH, K. A. THAXTER
Fac. of Med. Sciences, Mona Campus, The Univ. of the West Indies, Kingston 7, Jamaica

Abstract: Current treatment strategies for drug addiction often result in relapse due in part to the anhedonic effects of drug withdrawal. Signs and symptoms of withdrawal are in turn due to increased sympathetic activity. This study investigated the effectiveness of a patented nutritional supplement regime consisting of fish oil and megavitamins (developed by Dr. A. Salako) in alleviating the withdrawal symptoms of amphetamine and cocaine addiction; and its effects on

serum catecholamines and cardiovascular indices. Thirty-six male Sprague-Dawley rats (250 - 350 g) were randomly divided into 3 groups (n = 12) and exposed to a biased conditioned place preference paradigm (CPP), utilizing a 3-chambered box and an 8-day conditioning schedule. On alternate days of conditioning, 2 groups of rats received either cocaine hydrochloride (20 mg/kg/ml, *i.p.*) or amphetamine hydrochloride (5 mg/kg/ml, *i.p.*) in the non-preferred white chamber, and saline (1 ml, *i.p.*) in the preferred black chamber. The third group (controls) received saline in both chambers. Post conditioning, each rat was placed in the neutral grey chamber and allowed to freely explore the CPP box for 20 minutes. Addicted rats spent at least 80% of their time in the drug-paired white chamber and were subsequently administered increasing dosage of cocaine (20-30 mg/kg/ml, *i.p.*) or amphetamine (5 -7 mg/kg/ml, *i.p.*) over an additional 6 days. Addicted rats and controls were then randomly subdivided equally into groups of rats fed chow containing the nutritional supplement or normal rat chow for 8 weeks, and their behavior re-examined in the CPP. ELISA analysis of tail blood samples for catecholamines (dopamine, norepinephrine and epinephrine) and mean arterial pressure (MAP) measurements were done before CPP exposure (baseline), after a 3-day drug-withdrawal period and following the 8-week supplementation period. Supplemented addicted rats showed significant decreases ($p<0.05$) in number of entries and time spent in the white chamber on repeat performance in the CPP; while non-supplemented addicted rats continued to show significant preference for this chamber. Nutritionally supplemented drug-exposed rats showed significantly lower MAP values ($p<0.05$) than their non-supplemented counterparts. Serum catecholamines measured at baseline, after withdrawal and following the supplementation period did not differ significantly from baseline. The nutritional supplementation-induced decline in addictive behavior to amphetamine and cocaine is thus likely to be a central effect. Further studies into the effects of the nutritional supplement on brain catecholamine levels and the mechanism of action are needed.

Title: Dopamine-beta-hydroxylase inhibition potentiates cocaine effect on dopamine release in the medial prefrontal cortex

Authors: P. DEVOTO[1,3], R. FRAU[1], L. FATTORE[4], *W. FRATTA[2], G. L. GESSA[3]
[1]Dept. of Biomed. Sci., [2]Dept. of Neurosci., Univ. of Cagliari, Monserrato, Italy; [3]Guy Everett Lab., Monserrato, Italy; [4]CNR Neurosci. Inst., Cagliari, Italy

Abstract: Several preclinical and clinical evidence support an important role for dopamine-beta-hydroxylase (DBH) inhibition in the ability of disulfiram in reducing cocaine use. The present study was aimed at characterizing the impact of the co-administration of DBH inhibitors and cocaine in either naïve and cocaine-experienced rats, by mean of neurochemical and behavioral approaches. In naïve rats, DBH inhibitors significantly increased extracellular dopamine levels in the medial prefrontal cortex (mPFC), but not in the nucleus accumbens, as measured by microdialysis. Conversely, DBH inhibitors decreased extracellular noradrenaline concentrations in both cerebral areas. Notably, the acute pre-treatment with DBH inhibitors before cocaine injection (10mg/kg, IP) dramatically potentiated the extracellular dopamine augmentation produced by cocaine alone, in the mPFC, but not in the nucleus accumbens. Notably, the dopamine imbalances measured in the mPFC of DBH inhibitors-cocaine treated rats were correlated with behavioral impairments related to cortical dopaminergic dysregulations, including sensorimotor gating deficits and reduced social investigations. Conversely, no significant difference on the motor activity parameters between cocaine- and cocaine-DBH inhibitors treated rats were found. Finally, in rats previously trained to intravenously self-administer cocaine, DBH inhibitors prevented cocaine-induced reinstatement of drug seeking and the neurochemical assays revealed that drug combination elicited an enhancement of the increase in the extracellular dopamine fluctuations in the mPFC equivalent to those observed in naïve rats. Collectively, these results suggest that DBH inhibitors prevent cocaine-seeking reinstatement by the enhancement of cocaine effects on dopamine release selectively in the mPFC, and that this elevated cortical dopamine level might exert a negative influences on perceptual and emotional processes. Moreover, they also may underpin the reported clinical observations of paranoia and other hallucinatory states in cocaine-addicted individuals under disulfiram therapy.

Title: Behavioral sensitization elicited by Coca-paste, a drug widely consumed in Latin America, and the influence of caffeine as its main adulterant

Authors: *C. SCORZA[1], J. P. PRIETO[1], M. N. MEIKLE[1], X. LÓPEZ-HILL[1], M. GALVALISI[1], J. URBANAVICIUS[1], J. A. ABIN-CARRIQUIRY[2]
[1]Lab. of Cell Biol., [2]Dept. of Neurochemistry, Inst. de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay

Abstract: Coca-paste (CP) is an illicit drug of abuse. Despite its high prevalence and distribution throughout South America it has not been extensively studied. CP is an intermediate product of the cocaine alkaloid extraction process from coca leaves. It has a high content of cocaine base mixed with other chemical substances (impurities) and it is adulterated when it reaches the consumers. We have demonstrated that cocaine (base) and caffeine (as an active adulterant) are the main components which underlie the stimulant effect induced by acute injection of CP seized samples, and they act in an additive fashion when achieved specific proportions. However, their roles in a CP repeated administration have not been studied so far.
Firstly we evaluated the behavioral sensitization phenomenon elicited after a repeated administration of a CP seized sample in comparison with that induced by cocaine. Secondly and similarly to what was determined for acute treatment, the specific role of cocaine and caffeine in the induction of the CP behavioral sensitization was also investigated.
Male Wistar rats were intraperitoneally injected during 5 days with CP at an equivalent dose of 10 mg/kg of cocaine, cocaine (10 mg/kg) and vehicle. Additionally, other series of experiments were done in which animals were injected during 3 days with cocaine, the combination of cocaine and caffeine (at the same proportions usually found in CP seized samples) and vehicle. For both experiments, after 5 withdrawal days a challenge with each treatment was done. The animal motor activity was registered along the treatments by means of the Open Field paradigm and the Ethovision video-tracking software.
Our results showed that after 5 days of treatment, CP and cocaine induced the expression of behavioral sensitization. A 3 days cocaine treatment was not enough to elicit the expression of sensitization although a specific combination of cocaine and caffeine was.
These results highlight the relevance of caffeine in the development of addiction to CP since caffeine, as main active adulterant, could be able to accelerate the neural changes involved in the expression of the behavioral sensitization elicited by CP. These data may contribute to the understanding of the high dependence, craving and relapse in CP addicts.

Title: The effects of environmental enrichment on methamphetamine self-administration and reinstatement

Authors: *C. E. WILMOUTH, M. BARDO
Dept. of Psychology, Univ. of Kentucky, Lexington, KY

Abstract: While environmental enrichment is known to reduce the sensitivity to the reinforcing properties of various stimulant drugs, little is known about its effects on methamphetamine (METH) self-administration or reinstatement of METH seeking. In contrast to other stimulants such as cocaine and methylphenidate, a primary mechanism of action for METH is on the vesicular monoamine transporter in brain (VMAT2). The present experiment examined whether environmental enrichment alters METH self-administration, extinction and/or cue-induced reinstatement. Male Sprague-Dawley rats were reared in either enriched or isolated conditions from postnatal day 21 to 65 and then were implanted with jugular catheters. Following recovery, rats underwent an autoshaping procedure to learn to lever press for methamphetamine (0.1 mg/kg/infusion) for 10 days. All rats were then run in a dose-response experiment with 8 METH unit doses (0.0, 0.001, 0.01, 0.03, 0.05, 0.1, 0.3 or 0.5 mg/kg/infusion) presented in semi-random order. A 14-day extinction procedure then was conducted and followed immediately by cue-induced reinstatement. The intake of METH self-administered by enriched rats did not significantly differ from the isolated controls at any of the doses tested. During the extinction phase, however, enriched rats exhibited lower levels of drug seeking behavior and showed lower levels of cue-induced reinstatement compared to isolated controls. Thus, while enriched rearing does not attenuate the reinforcing effects of methamphetamine, it reduces methamphetamine seeking after a period of extinction. These preclinical findings suggest that environment-based therapeutic approaches may be useful for reducing relapse among METH abusers.

Title: Early ontogeny of d-amphetamine-induced one-trial behavioral sensitization

Authors: *C. M. NUQUI, A. T. QUIROZ, C. M. MARTINEZ, S. A. MCDOUGALL
Dept. of Psychology, California State Univ., San Bernardino, CA

Abstract: Although adult rats of various ages exhibit one-trial behavioral sensitization, young rats only show one-trial sensitization during a narrow ontogenetic window that varies depending on the psychostimulant administered. For example, cocaine induces robust one-trial behavioral sensitization on postnatal day (PD) 21, whereas methamphetamine produces strong behavioral sensitization at only younger ages (PD 12-PD16). Because these psychostimulants differ in a variety of ways (e.g., brain half-life, selectivity at monoamine transporters, mechanism of action, etc.), it is uncertain what factors are responsible for the different sensitization profiles exhibited by young rats. Among amphetamine-like compounds, d-amphetamine and methamphetamine are readily dissociable in terms of pharmacokinetic factors, although they do share the same mechanism of action. If mechanism of action is the critical factor determining the occurrence of behavioral sensitization during early ontogeny, then it would be predicted that d-amphetamine should have a sensitization profile similar to methamphetamine and different from cocaine. To examine this issue, the ontogeny of d-amphetamine-induced one-trial behavioral sensitization was characterized using preweanling and preadolescent rats. In the first experiment, rats were injected with saline or d-amphetamine (4 or 8 mg/kg) in an activity chamber or home cage on PD 12, 16, 20, or 24. One day later, rats were challenged with 2 mg/kg d-amphetamine and distance traveled was measured in activity chambers for 120 min. In a separate experiment, a broad dose range of d-amphetamine was employed in order to ensure that the absence of sensitized responding was not the result of an inappropriate dosing regimen. Results showed that a single pretreatment injection of d-amphetamine caused a strong sensitized response at younger ages (i.e., on PD 13 and PD 17), which was not dependent on environmental context. Rats did not display d-amphetamine-induced sensitization on PD 21, nor was context-dependent sensitization evident on PD 25 even when a broad dose range of d-amphetamine was used. This pattern of d-amphetamine-induced one-trial behavioral sensitization is nearly identical to the pattern produced by methamphetamine, while the ontogeny of cocaine-induced one-trial sensitization is

distinctly different. The disparate sensitization profiles resulting from repeated d-amphetamine and cocaine treatment may be a consequence of their mechanism of action (i.e., d-amphetamine functions as a dopamine releaser, while cocaine is a transport inhibitor).

Title: Using taste reactivity to track the development of responses to drug cues

Authors: *E. COLECHIO, P. S. GRIGSON
Dept Neurosci, Penn State Hershey, HERSHEY, PA

Abstract: Addiction can be devastating for addicts, their families, and for society as a whole; the emotional and economic costs are astounding. Much of this damage occurs because addiction is a brain disease of chronic relapse. Stress, the drug itself, and drug-associated cues can repeatedly initiate drug-seeking and drug-taking, even following prolonged periods of abstinence. Drug-associated cues are particularly problematic as they utilize the innate learning and memory system – a system that is designed to remember associations and engage learned behaviors for a life time. It is, then, imperative that we understand how cues gain access to this system to engage drug-seeking and drug-taking behavior. Cues, it appears, can elicit drug-seeking in one of two ways. The cue can take on the positive reinforcing properties of the drug and thereby elicit approach (Wheeler et al., 2011). Alternatively, the cue can elicit a highly aversive opponent process which also elicits approach and drug-seeking, but in this case, in an effort to correct the aversive state (see Grigson, 2008; Wheeler et al., 2008). While important, these prior studies measured cue-induced positive and negative affect only at the end of training (i.e., after the 'addictive' behavior was acquired). Here we evaluated this behavior during acquisition, on a trial by trial basis. Specifically, rats received intraoral infusion of a saccharin cue once per min for 30 min. Thereafter, they were given 90 min to self-administer cocaine. Affect was assessed by measuring aversive taste reactivity behavior (i.e., gapes) throughout each daily intraoral infusion period. The results revealed large and small drug-takers following a single taste-drug pairing. As a group, large drug-takers exhibited significantly more gapes in response to the intraoral infusion

of the drug-paired saccharin cue. Thereafter, they were faster to take the first infusion of cocaine, they exhibited greater load-up (i.e., a longer run of rapid drug infusions at the start of the session), and they continued to seek drug even when drug was not available. Some rats, then, are more resilient and others more vulnerable. Vulnerable rats acquire the aversive opponent process very quickly and these rats exhibit greater seeking and taking of drug. This work was supported by DA009815.

Title: Inactivation of the basolateral amygdala blocks the expression of cue-induced hyperactivity

Authors: *G. W. DIEHL[1], T. A. PAINE[2]
[1]Oberlin, ; [2]Neurosci., Oberlin Col., Oberlin, OH

Abstract: Background: Presentation of drug-associated cues increases drug craving, which in turn increases the likelihood of relapse. Furthermore, drug-associated cues reinstate drug-seeking behavior in self-administration paradigms, reinstate place preferences and increase locomotor activity in non-human animal models of addiction. Drug-associated cues are thought to acquire salience through classical conditioning. Understanding the neural systems by which drug-associated cues acquire salience and promote relapse may enable us to develop more effective treatments for addiction. Here we examine the ability of basolateral amygdala (BLA) inactivation to block the expression of drug cue-induced locomotor activity.
Methods: Male Sprague Dawley rats were implanted with cannulae aimed at each BLA and allowed to recover. Next, rats were habituated to locomotor activity chambers over three 60-min sessions; these data were used to divide rats into cocaine-paired and saline-paired groups. Drug-cue pairing was then established over 12 conditioning sessions. There were two types of conditioning sessions, cue present (a flashing yellow bicycle light and a metronome; CS+) and cue absent (CS-), which occurred on alternating days. Prior to CS+ sessions, rats in the cocaine-paired groups received cocaine (15 mg/kg, IP) and rats in the saline-paired group received saline (1 ml/kg). Prior to CS- sessions all rats received saline (1 ml/kg). Two days after conditioning, testing began. Prior to test sessions all rats were treated with saline (IP) and received bilateral

intra-BLA infusions of either saline (0.5 μL/side) or muscimol (25 ng/0.5 μL/side). Activity was then measured in the presence of the cue (CS+) or the absence of the cue (CS-).
Results: Cocaine-paired, saline-infused rats exhibited greater activity in the presence of the cue (CS+) than in the absence of the cue (CS-). Inactivation of the BLA reversed this effect. Activity of saline-paired rats was unaffected by either the presence of the cue or by intra-BLA muscimol infusions.
Implications: These data support the idea that the BLA is important for the expression of cue-induced activity, supporting previous findings using other models of cue-induced reinstatement. Additionally, these data support the use of locomotor activity monitoring in further study of the neural mechanisms underlying drug-associated cues.

Title: Neural mechanisms of methylphenidate's dose-dependent behavioral effects

Authors: *S. A. CARMACK, K. K. HOWELL, S. G. ANAGNOSTARAS
Univ. of CA, San Diego, La Jolla, CA

Abstract: Prescription psychostimulants containing methylphenidate (e.g. Concerta, Focalin, & Ritalin) are the mainstay of treatment for attention-deficit hyperactivity disorder (ADHD). In affected individuals, low doses reportedly reduce activity, improve attention, and reduce impulsivity. These low, therapeutic doses can also enhance learning in control populations, which has led to controversial off-label use of methylphenidate as a cognitive enhancer. We have recently developed a model using standard Pavlovian fear conditioning where we can consistently detect methylphenidate-induced memory enhancements at a low, clinically relevant dose and memory deficits at a high dose. These effects are dissociable from methylphenidate's other behavioral effects, including the induction of behavioral sensitization and conditioned

place preference. It is well established that methylphenidate inhibits both the dopamine and norepinephrine transporters, but the mechanisms underlying its cognitive enhancing and locomotor activating effects remain unknown. The present experiments investigated the neural mechanisms underlying methylphenidate's dose-dependent behavioral effects.

Title: Amphetamine-associated contextual learning produces a constellation of structural plastic changes of synapses in basolateral amygdala circuitry

Authors: *D. J. RADEMACHER[1], J. A. ROSENKRANZ[2], A. HETZEL[2], N. MENDOZA-ELIAS[2,3], G. E. MEREDITH[3]
[1]Translational Sci. and Mol. Med., Michigan State Univ., Grand Rapids, MI; [2]Dept. of Cell. & Mol. Pharmacol., [3]Dept. of Pharmaceut. Sci., Rosalind Franklin Univ. of Med. & Sci., North Chicago, IL

Abstract: Our earlier work (Rademacher et al., 2010) with amphetamine (AMPH) conditioned place preference (CPP), a widely used behavioral assay for context-induced drug-seeking, demonstrated that learning to associate a context with AMPH increased the number of asymmetric (excitatory) synapses and the excitatory drive in the basolateral amygdala (BLA). As it was not established how the increase in excitatory drive translated to the neural targets, immunohistochemistry with a cell specific marker and the stereological quantification of synapses was used in the present study to determine if context-drug learning alters the number of asymmetric and symmetric (inhibitory) synapses contacting gamma-aminobutyric acid (GABA) interneurons and/or pyramidal neurons in the synaptic circuit of the BLA. Rats were tested for place preference using a conditioning procedure that was performed in a three-chambered apparatus. One group of animals received injections of AMPH (1.0 mg/kg, i.p.) in one compartment on days 1, 3, and 5 and injections of saline in the other compartment on days 2 and 4. A second group, the delayed pairing control group, was subjected to the identical conditioning schedule with AMPH. However, these animals spent 4 hours in their home cages before being placed into the CPP apparatus. A third group received saline pairings only. Seventy-two hours

after place conditioning, animals were exposed to the CPP apparatus in a drug- and saline-free state and place preference was measured. After the test, animals were deeply anesthetized and transcardially perfused with fixative. Brain sections through the entirety of the BLA were processed for glutamate decarboxylase (GAD) immunohistochemistry to label all cellular structures of GABA interneurons. AMPH CPP increased the number of asymmetric synapses contacting spines and dendrites of BLA pyramidal neurons, multisynaptic boutons contacting BLA pyramidal neurons and interneurons, and symmetric synapses contacting the dendrites of interneurons. These data suggest that approach behavior to a context previously paired with drug is driven by a 'constellation' of structural plastic changes of synapses in BLA circuitry.

Title: Stimulation of adenosine A1 receptors in the nucleus accumbens reduces dopamine D1 receptor-induced cocaine seeking and D1-mediated phosphorylation of AMPA receptors

Authors: *B. HOBSON, C. E. O'NEILL, R. K. BACHTELL
Psychology and Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Chronic cocaine use can lead to an addiction that is especially difficult to treat because of the continuous potential for relapse. Stimulation of either AMPA glutamate or dopamine D_1 receptors in the nucleus accumbens (NAc) is sufficient to induce reinstatement of cocaine seeking in rodents. Identifying strategies to reduce the activity of these systems may shed light on the mechanisms involved in relapse, revealing potential therapeutic targets. Adenosine A_1 receptors co-localize with D_1 receptors on postsynaptic terminals of medium spiny neurons where they counteract D_1 receptor activity through opposing intracellular signaling. We hypothesized that dopamine D_1 stimulation in the NAc facilitates AMPA receptor activity to induce cocaine seeking and that stimulation of adenosine A_1 receptors in the NAc reduces D_1-mediated cocaine seeking by offsetting D_1 facilitation of AMPA glutamate activity. Male

Sprague Dawley rats self-administered cocaine during daily sessions over 3 weeks. Cocaine seeking was extinguished in 6 daily extinction sessions and reinstatement of cocaine seeking was induced by micro-infusion of the D_1 agonist, SKF 81297. We investigated the role of AMPA receptors in D_1-induced reinstatement using the AMPA receptor antagonist, CNQX, to block AMPA receptors, and viral-mediated gene transfer to bi-directionally modulate AMPA receptor activity in the NAc. Results show that either AMPA receptor blockade or downregulation of the GluA1 AMPA subunit impairs D_1-induced reinstatement. We next sought to determine whether D_1 stimulation facilitated AMPA receptor activity by analyzing synaptic phosphorylation of the GluA1 subunit. We observed that D_1 stimulation enhanced PKA-mediated GluA1^{S845} phosphorylation, an effect reversed by adenosine A_1 stimulation in the NAc. Finally, we tested the ability of A_1 stimulation in the NAc to inhibit D_1-induced reinstatement. Our results demonstrate that stimulation of A_1 receptors decreases D_1-induced cocaine seeking. Together, these findings suggest that A_1 receptor stimulation reduces D_1 facilitation of AMPA receptor phosphorylation in the NAc that is critical for D_1 receptor-mediated reinstatement.

Title: Deletion of Sorting Nexin 27 from dopamine neurons alters GABABR-GIRK currents and behavioral response to novelty

Authors: *M. B. MUNOZ[1,2], P. A. SLESINGER[1,3]
[1]Peptide Biol. Labs., Salk Inst., LA JOLLA, CA; [2]Biol. Sci., UCSD, La Jolla, CA; [3]Dept. of Neurosci., Mount Sinai Sch. of Med., New York, NY

Abstract: Natural rewards and addictive drugs increase the release of dopamine (DA) in the brain's reward circuit by augmenting the activity of dopaminergic neurons in the ventral tegmental area (VTA). Activation of G protein-gated inwardly rectifying potassium (GIRK or

Kir3) channels provides an important inhibitory signal for regulating the excitability of DA neurons. Here, we examined the effect of 5 daily injections of methamphetamine (2mg/kg) on GIRK signaling in mice (P33-42 days). Whole-cell patch clamp electrophysiology from DA neurons in acutely prepared slices containing the VTA was used to assess GIRK channel activity. We bath applied GABAB or dopamine D2 receptor agonists, baclofen and quinpirole, respectively, and observed an ~50% reduction of GABAB-GIRK currents with no change in D2R-GIRK currents. Psychostimulant-sensitive sorting nexin 27 (SNX27) is known to regulate GIRK channel surface expression and inhibitory currents. Thus, drugs of abuse have the potential to increase SNX27 trafficking of GIRK channels, dis-inhibiting DA neurons and altering reward responding in vivo. To examine the impact of SNX27 on GIRK channel trafficking in the reward pathway, we generated mice lacking SNX27 selectively in DA neurons by crossing conditional SNX27 mice (SNX27lox/lox) with DAT-Cre (Slc6a3+/cre) transgenic mice. In contrast to whole animal knockouts of SNX27, which are postnatal lethal, DA-specific knockouts are indistinguishable from wild-type littermates. DA neurons in VTA-containing slices from knockout animals exhibited similar capacitance, resting potential, and action potential duration to wild-type neurons. However, the induced firing frequency was higher in DA neurons lacking SNX27, suggesting an increase in excitability. Furthermore, GABAB-GIRK currents in DA neurons were reduced by ~70% compared to controls (floxed- and cre+-only animals), similar to results observed with repeated methamphetamine in wild-type mice. D2R-GIRK currents in DA neurons from SNX27 knockout mice were indistinguishable from those in wild-type mice. Behaviorally, mice lacking SNX27 in DA neurons exhibited an enhanced response to novelty with normal basal activity levels. These data identify a novel pathway for reward processing involving SNX27 and GIRK channels in VTA DA neurons and highlight SNX27 as a promising therapeutic target for addiction and other complex psychiatric disorders.

Title: Inducible and tissue specific knock-down of the serotonin 1B receptor

Authors: *K. M. NAUTIYAL[1], K. F. TANAKA[4], C. BLANCO[2], S. E. AHMARI[2], R. HEN[3]

Abstract: The serotonin 1B receptor (5-HT1B R), a GPCR that inhibits neurotransmitter release in axon terminals of serotonergic and non-serotonergic neurons, has been implicated in aggressive behavior and impulsivity using pharmacology and constitutive knock-out mouse models. The broad localization of 5-HT1B R in the basal ganglia, hippocampus, thalamus, cerebellum and raphe leaves open the possibility for the modulation of various neurotransmitter systems involved in the regulation of aggressive and impulsive behavior. Given evidence of serotonergic modulation of brain development, an inducible and tissue specific knock-out is necessary to delineate the role of 5-HT1B R in aggression and impulsivity. We have therefore generated a mouse line that permits temporal and spatial regulation of 5-HT1B R. A tetracycline operator (tetO) has been inserted between the promoter and coding region of the 5-HT1B R (tetO1B). Receptor binding and in situ hybridization revealed that these tetO1B mice have normal basal 5-HT1B R expression in the brain compared to 129 WT mice. Crossing tetO1B mice to transgenic mice expressing the tetracycline-dependent transcriptional silencer (tTS) under the control of β-Actin, CamKII or Pet promoters yielded mouse lines with tissue specific and inducible knock-down of 5-HT1B R . Initial characterization with autoradiography and in situ hybridization reveals promoter-specific 5-HT1B R expression patterns. β-Actin -tTS/tetO1B mice have complete elimination of all brain 5-HT1B R. CamKII-tTS/tetO1B mice lack 5-HT1B heteroreceptors in forebrain regions including the striatum, cortex and hippocampus. Pet-tTS/tetO1B mice have reduced autoreceptor 5-HT1B mRNA in the raphe. Behavioral assays using these mouse lines will assess the relative contribution of hetero- and auto-receptors to aggression and impulsivity. The developmental impact of altered 5-HT1B R expression in the brain will also be examined.

Title: Modulation of behavior by 5-HT6 receptors in mice

Authors: R. J. BLUETT[1], T. P. SABORIDO[1], M. A. BUENDIA[1], D. P. BERMINGHAM[2], C. E. KILLINGER[1], *G. D. STANWOOD[1]
[1]Pharmacol., [2]Neurosci. Grad. Group, Vanderbilt Univ. Sch. of Med., NASHVILLE, TN

Abstract: Serotonin is a critical modulator of stress, anxiety, and depression. Variations in the 5-HT6 receptor gene, in particular, have been associated with the pathophysiology and pharmacological treatment of several neurological and neuropsychiatric diseases. It has been hypothesized that 5-HT6 receptors may be a useful therapeutic target in the regulation of mood and cognition. In the current studies, we first examined the behavioral effects of a specific 5-HT6 receptor antagonist (SB-399885) and agonist (EMD-386088) in mice. Acute SB-399885 produced a dose-dependent sedative effect, while EMD-386088 induced hyperactivity. SB-399885 also decreased immobility in the forced swim test, suggesting a potential antidepressant effect. EMD-386088 had no effect on behavioral despair at the doses tested. We also examined behavioral phenotypes of 5-HT6 receptor knockout mice. These mutants did not display phenotypic variations in body weight, body temperature, anxiety or simple learning tasks. However, 5-HT6 receptor null mice were mildly hyperactive in open field tests and also exhibited slight decreases in immobility in tests of behavioral despair. 5-HT6 receptors are expressed prominently in dopamine target regions such as the striatum and frontal cortex, suggesting that the 5-HT6 receptor may be involved in modulating dopaminergic signaling. Preliminary immunoblotting data suggests that dopamine D1 receptors are significantly upregulated in the striatum of 5-HT6 receptor knockout mice, and are modestly decreased in the medial frontal cortex. SB-399885 significantly decreased anxiety responses of D1 receptor null mice as demonstrated by increased time exploring the open sections of an elevated zero maze. Taken together, these data suggest that 5-HT6 receptors affect motor activity and emotional behaviors and may serve as a substrate for functional interactions between the serotonin and dopamine systems.

Title: Behavioral and temperature effects of tramadol in mice lacking the genes for monoamine oxidase (MAO) A and B or the serotonin transporter (SERT)

Authors: *M. A. FOX[1], M. G. PANESSITI[1], K. CHEN[2], J. C. SHIH[2], D. L. MURPHY[1]
[1]Lab. Clin. Sci., NIMH, BETHESDA, MD; [2]Dept. of Pharmacol. and Pharmaceut. Sci., USC, Los Angles, CA

Abstract: Tramadol is an atypical opioid, which in addition to relatively weak actions on opioid receptors affects the reuptake and release of serotonin and norepinephrine, resulting in increased extracellular fluid (ECF) serotonin and norepinephrine levels. In mice, drugs that increase ECF serotonin levels can have a number of behavioral and physiological effects. For example, a cluster of behaviors (the "serotonin syndrome," S/S) is induced by increased serotonin levels, behaviors which include head weaving, forepaw treading, backward movement, hind limb abduction, Straub tail, tremor and low body posture. In addition, serotonin-enhancing drugs have been shown to induce hypothermia in mice. These behavioral and temperature effects are enhanced in conditions of high levels of ECF serotonin, for example following administration of a serotonin-enhancing drug such as the serotonin precursor 5-hydroxy-L-tryptophan (5-HTP), a serotonin reuptake inhibitor (SRI) or a monoamine oxidase inhibitor (MAOI). In addition, several genetic manipulations lead to high baseline ECF serotonin levels in mice, for example mice lacking the serotonin transporter (SERT) or mice lacking MAO A and B. We have previously shown that administration of various serotonin-enhancing drugs induce enhanced S/S behavioral and hypothermic effects in mice lacking SERT. Here, we compare the behavioral (overall S/S behavioral score) and temperature effects of tramadol (60 mg/kg ip) in mice lacking MAOA and B or SERT. Tramadol induced the overall S/S cluster of behaviors in all wildtype (WT) and knockout (KO) mice compared to vehicle, and these behaviors were increased in both MAOA/B-KO mice (~2-fold increase) and SERT-KO mice (~1.5-fold increase) compared to their respective controls. Further, tramadol induced a hypothermic response in all WT and KO mice compared to vehicle, although this effect was decreased in both MAOA/B-KO and SERT-KO mice compared to their respective WT controls. Genetic manipulations such as these evaluated in mice may model and predict adverse effects of many drugs including tramadol, MAOIs and SRIs in humans, as polymorphisms in the SERT and MAO genes in humans are known to reduce gene function. These polymorphisms have begun to be studied in individuals who have been treated with such drugs, taken these drugs in overdose and in suicide attempts, with some similar S/S and physiological consequences.

Title: Effects of repeated exposure to MDMA on $5HT_{1a}$ autoreceptor function: Behavioral and neurochemical responses to 8-OHDPAT

Authors: *D. ARONSEN[1,2], B. ABRAHAM[2], J. COLUSSI-MAS[2], J. DO[2], K. JONES[2], S. SCHENK*[2]
[1]Psychology, [2]Victoria Univ. of Wellington, Wellington, New Zealand

Abstract: A consistent effect of repeated exposure to MDMA is a decrease in tissue levels of serotonin (5HT). A variety of behavioral and neurochemical tests were conducted to determine whether the tissue deficits could be explained by an increased sensitivity of the $5HT_{1a}$ autoreceptor. Tests were conducted two weeks following MDMA exposure (either 300 mg/kg self-administered during 25-40 daily 2 hr test sessions or 4 injections of 10.0 mg/kg, ip, administered at 2 hr intervals in a single day). The response to several doses of the $5HT_{1a}$ agonist, 8-OHDPAT (0.003-0.5 mg/kg, sc), was measured as lower lip retraction (LLR), hypoactivity, hypothermia and 5-hydroxytryptophan (5HTP) accumulation following decarboxylase inhibition. 8-OHDPAT produced a dose-dependent increase in LLR and hypothermia and a decrease in all other measures, including the accumulation of 5HTP following decarboxylase inhibition. MDMA decreased tissue levels of 5HT and the accumulation of 5HTP but these effects were not reflected in changes in autoreceptor sensitivity. The only effect of MDMA pretreatment was a leftward shift in the dose effect curve for 8-OHDPAT produced hypothermia. Because all of the effects except for hypothermia have been attributed to $5HT_{1a}$ autoreceptor activation, the data suggest that MDMA failed to alter the sensitivity of this receptor. Hypothermia, however, has been attributed to postsynaptic $5HT_{1a}$ activation and this response became supersensitive following MDMA exposure. The data suggest that the decrease in tissue levels of 5HT produced by MDMA is due to a decrease in tryptophan hydroxylase activity and is not related to supersensitivity of the $5HT_{1a}$ autoreceptor.

Title: Fibroblast growth factor 8 deficiency impacts anxiety-like behavior in response to restraint stress in mice

Authors: *L. R. BROOKS, C. L. ENIX, S. C. RICH, C. A. LOWRY, P.-S. TSAI
Univ. of Colorado Boulder, Boulder, CO

Abstract: Vulnerability to a number of psychiatric illnesses, including anxiety, may be neurodevelopmental in origin. Animal models suggest that serotonin (5-HT) neurons in the dorsal raphe nucleus (DR) are needed to establish functional stress- and anxiety- related circuitries, and environmental stressors can affect these circuits to precipitate anxiety-like behaviors. Fibroblast growth factor 8 (Fgf8) is critical for the development of 5-HT neurons, and its deficiency has previously been shown to lead to increased trait anxiety-like behavior in mice. However, it is unclear if the development of 5-HT neurons underlying stress- induced anxiety is also dependent on Fgf8 signaling. Given that stress is an important factor in the onset and expression of anxiety in humans, this study examined both stress-induced anxiety and 5-HT cell numbers in relevant DR subdivisions (dorsal, ventral, ventrolateral, caudal, interfascicular) in wildtype (WT) and *Fgf8*-deficient mice. WT and *Fgf8*-deficient mice were assigned to either a non-stressed or stressed group. Following one hour of no stress or restraint stress, adult *Fgf8*-deficient and WT mice were immediately tested for anxiety-like behavior in the elevated plus-maze (EPM). As expected, non-stressed WT mice spent significantly more time exploring the open arms compared to non-stressed *Fgf8*-deficient mice and their WT stressed counterparts. Surprisingly, stressed Fgf8-deficient mice spent significantly more time in the open arms than their non-stressed controls, suggesting that the stressed Fgf8 Het mice are less anxious than their non-stressed counterparts. There was no genotype difference in the stressed group. These findings suggest that stress impacts anxiety-like behavior differentially in WT and *Fgf8*-deficient mice. Neuroanatomical data support these findings by demonstrating decreases in both the

number and density of neurons immunopositive for the serotonergic marker, tryptophan hydroxylase, in subregions of the DR associated with stress- and anxiety-like behaviors. These results expand our knowledge on the elements governing the development of specific subpopulations of 5-HT neurons, their functional integrity, and their relationship to stress-induced anxiety-related behavior.

Title: Characterization of the highly selective 5-HT2C receptor agonists lorcaserin and CP-809101 on food and nicotine motivated behaviors in the rat

Authors: *G. A. HIGGINS[1,2], L. B. SILENIEKS[1], W. LAU[1], I. A. M. DE LANNOY[4], D. K. H. LEE[4], A. D. LE[5,2], P. J. FLETCHER[5,3]
[1]Intervivo Solutions Inc, Toronto, ON, Canada; [2]Pharmacol., [3]Psychology, U. Toronto, Toronto, ON, Canada; [4]NoAb BioDiscoveries, Mississauga, ON, Canada; [5]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: The therapeutic potential of a drug is governed by both its clinical efficacy and side effect property. Experimental evidence supports 5-HT2C agonists as offering therapeutic potential in indications such as obesity and nicotine dependence although relatively few members of this class have been evaluated. Agonist specific features such as intrinsic efficacy, functional and target selectivity and pharmacokinetics property highlight the need to evaluate multiple 5-HT2C agonists in terms of behavioural profiles predictive of clinical efficacy and side effect liability. Therefore in this study, we have evaluated the highly selective and chemically diverse 5-HT2C agonists CP-809101 and lorcaserin, and the prototypic 5-HT2C agonist Ro 60-0175 on (1) behaviors motivated by either food or nicotine reinforcement, (2) a nicotine drug discrimination procedure, and (3) side effect profiles. Furthermore plasma levels of lorcaserin were determined at a dose (1 mg/kg SC) effective against food and nicotine motivated behavior. Adult, male Sprague-Dawley (SD) rats were used throughout, except for the nicotine self-administration experiments which utilized Long Evans (LE) rats. In rats trained to discriminate nicotine (0.3 mg/kg SC) from saline using standard operant procedures, neither CP-809101 (0.3-

6 mg/kg SC), lorcaserin (0.3-3 mg/kg SC), nor Ro 60-0175 (0.3-2 mg/kg SC) engendered reliable nicotine responding across a pharmacologically relevant dose range, however in combination tests each produced a rightward shift in the nicotine D/R implying a weakening of the discriminative property of nicotine. In separate studies, each drug similarly reduced responding for both intravenous nicotine (0.03 mg/kg/infusion) and food made available under an FR5TO20s schedule of reinforcement (e.g. CP-809101: nicotine (infusions earned): veh=26.5+2.0, 1 mg/kg=20.6+1.6, 3 mg/kg=18.3+1.5, $P<0.01$; food (pellets earned): veh=148+3, 1 mg/kg=135+4, 3 mg/kg=104+10, $P<0.01$). In tests of feeding induced by either palatability or 22 h deprivation, each drug similarly reduced overall intake although palatability-induced feeding seemed the more sensitive. At high doses, both CP-809101 and lorcaserin (3-6 mg/kg) produced behavioural signs reflective of malaise, a reported side-effect of lorcaserin at supratherapeutic doses (Schram et al, 2011, Clin. Pharmacol. Ther. 89: 683-692). At a dose of 1 mg/kg SC, plasma levels of lorcaserin in LE and SD rats were similar (LE: 118+14 ng/ml; SD: 163+21 ng/ml) further suggesting equivalent effects of 5-HT2C agonists against nicotine and food motivated behaviours.

Title: Reduced 5-HT1A regulation of anxiety-like behavior in adolescent male rats

Authors: *A. E. ARRANT, C. M. KUHN
Duke Univ., DURHAM, NC

Abstract: Adolescence is marked by normal changes in behavior such as peaks in novelty seeking and risk taking as well as the emergence of mood disorders. Ongoing development of neural circuits between the prefrontal cortex and limbic brain regions, as well as the

monoaminergic systems that modulate these pathways, may underlie these changes in behavior. Acute treatment with indirect serotonergic agonists typically produces increases in behavioral inhibition in rodent anxiety tests. Prior studies in our lab showed that adolescent rats are less sensitive to these anxiogenic effects, and that drug-stimulated increases in extracellular serotonin do not completely explain this insensitivity. The goal of this study was to investigate the role of serotonin receptors in adolescent insensitivity to serotonergic behavioral inhibition.
Adult (PN67-70) and adolescent (PN28-32) rats were tested in the light/dark (LD) test for anxiety-like behavior after administration of the mixed 5-HT2 agonist meta-chlorophenylpiperazine (mCPP, 0.5 or 1 mg/kg i.p.), the 5-HT1A agonist 8-hydroxy-2-(dipropylamino)tetralin (8-OH DPAT, 0.25 or 0.5 mg/kg i.p.), or vehicle. mCPP was similarly anxiogenic to each age group, but 8-OH DPAT produced greater increases in anxiety-like behavior in adults compared to adolescents. Treatment with 8-OH DPAT (0.5 mg/kg i.p.) also produced greater activation of brain regions associated with anxiety-like behavior in adult rats, as measured by c-Fos immunostaining. We then performed site-specific injection of 8-OH DPAT into the prelimbic region of the medial prefrontal cortex to determine if the prefrontal cortex could be involved in the reduced effects of systemic 8-OH DPAT in adolescents. Infusion of 8-OH DPAT (100 or 200 ng) into the prelimbic cortex produced anxiogenic effects in adults, but not adolescents.
These data indicate that 5-HT1A modulation of anxiety-like behavior is immature in male adolescent rats. Available data generally demonstrate mature levels of 5-HT1A expression by adolescence in rodents, but experiments in both rodents and humans show immature connectivity between the prefrontal cortex and limbic brain regions such as the amygdala. The lack of anxiogenic effects of 8-OH DPAT in adolescent rats may reflect this immature circuitry. Reduced serotonergic regulation of these neural pathways in adolescents could result in altered responses to drugs that target the serotonergic system, including therapeutic drugs such as SSRIs or drugs of abuse such as the psychostimulants cocaine and MDMA.

Title: Correlation between 5-HT1A mRNA expression and number of mitotic and progenitor cells in the human hippocampus

Authors: A. N. SANTIAGO[1], S. A. KASSIR[1], S. MIGLIARINI[2], M. J. BAKALIAN[1], K. M. BURKE[1], G. MUSOLINO[1], C. B. PALAVICINO-MAGGIO[1], G. B. ROSOKLIJA[3], A. J. DWORK[4], J. J. MANN[5], M. PASQUALETTI[2], R. HEN[6], V. ARANGO[5], *M. BOLDRINI[5]

Abstract: The serotonin 1A receptor (5-HT1AR) is implicated in morphogenesis. Stimulation of the 5-HT1A receptor is necessary for the proliferative response of cells treated with serotonin: antagonists of 5-HT1A receptor block this effect; 5-HT1AR knock-out mice do not show increased hippocampal neurogenesis and behavioral changes in response to fluoxetine. In response to stress, 5-HT1AR density and mRNA levels decrease via adrenal axis stimulation and hippocampal neurogenesis is reduced. In subjects with major depression (MDD) treated with antidepressants we found more mitotic and neural progenitor cells (NPCs) than in untreated MDDs and controls, selectively in the anterior dentate gyrus (DG). We aimed to asses if more mitotic cells and NPCs were associated with more 5-HT1AR mRNA in the human DG. Psychological autopsy identified 10 untreated subjects with major depression (MDD), nine MDD treated with antidepressants, nine non-psychiatric controls, matched for age, sex and postmortem interval. At autopsy, brain pH, neuropathology, and toxicology exams were performed. Frozen whole hippocampi were fixed and sectioned at 50 μm, mitotic cells and NPCs labeled by immunocytochemistry on sections at 2-mm intervals thoughout the anterior, mid and posterior DG and their number estimated by stereology. We carried out 5-HT1AR in situ hybridization using an 35S-labeled 5-HT1AR riboprobe and quantified the density of mRNA in CA1, CA3, DG and white matter.
In MDDs treated with tricyclic antidepressants (TCA), selective serotonin reuptake inhibitors (SSRI) or lithium, 5-HT1AR mRNA density (μCi/g) in the anterior DG correlates positively with mitotic cell density ($r = .987$, $p = .002$). In untreated MDDs, density of NPCs in the mid DG

correlates positively with 5-HT1AR mRNA density in the mid CA1 (r =.766, p=.027) and number of NPCs in the mid DG correlates with 5-HT1AR mRNA density in CA3 (r =.782, p=.022). In controls there is a positive correlation between number of NPCs in the anterior DG and 5-HT1AR mRNA density in the CA3 (r =.782, p=.038).
Results suggest role of 5-HT1AR in DG cell replication in the human brain. A larger sample will allow differentiating the effect of different classes of antidepressants.

Title: Prenatal fluoxetine exposure: Mitigation of social, emotional, motor and cognitive abnormalities with neonatal tactile stimulation.

Authors: *J. A. MILSTEIN[1], K. PLACEK[2], W. EHRIG[3], C. M. BOUSLOG[2], L. M. SITZ[2], D. O. FROST[1,4], A. M. BAILEY[2]
[1]Pharmacol., Univ. of Maryland, Baltimore, Baltimore, MD; [2]Psychology, [3]Biochem., St. Mary's Col. of Maryland, St. Mary's City, MD; [4]Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: The selective serotonin reuptake inhibitor (SSRI) fluoxetine (FLU) is the recommended antidepressant treatment for maternal depression during pregnancy, but studies remain inconclusive regarding the long-term effects of prenatal exposure on offspring. In rodent models, prenatal FLU exposure has caused long-term anomalies, including increased anxiety and depression-like behaviors, deficits in motor development, altered cognitive ability, and decreased complexity in frontal lobe neuronal structure. Tactile stimulation, a form of environmental enrichment, offers potential as an intervention to compromised neurodevelopment by increasing dendritic spine length and density in the rat frontal cortex following neonatal cortical injury,

reducing anxiety-like behaviors in adult rats subject to early-life emotional stress, and serving a neuroprotective mechanism to the hippocampus following induced neonatal hypoxia-ischemia in rats. We aimed here to test the long-lasting effects of neonatal tactile stimulation on subjects exposed to FLU prenatally. Female Long-Evans rats were administered FLU (10mg/kg/day) or a vehicle solution via the drinking water from gestational day 1 (GD1) though postnatal day 7 (PD7). One-half of the pups from each litter were given tactile stimulation from PD3-PD21. During the adolescent period, PD25-PD35, animals were measured for social play behavior. Males exposed to FLU and given tactile stimulation showed fewer defensive behaviors (p=.053) and more social interaction than non-stimulated FLU-exposed peers (p < .001). At PD 90 all animals were tested for motor ability in the rotarod test, for spatial learning and reversal in an operant box, and for emotionality in an elevated plus maze and forced swim test. Fluoxetine impaired motor performance in females on the rotarod task (p = .051). In the operant box, FLU-exposed females were no different in acquisition of a spatial rule but showed a significant increase in the number of perseverative errors (p = .013) when the spatial rule was reversed. In the elevated plus maze, males exposed to FLU but given tactile stimulation showed decreased anxiety-like behavior compared to non-stimulated FLU-exposed peers (p = .002). Finally, females exposed to FLU showed a significant increase in time spent immobile (p=.026) in the forced swim test. The interaction between prenatal exposure to FLU and neonatal tactile stimulation on behavioral outcomes will be discussed.

Title: Fluoxetine exposure during adolescence disrupts spatial memory performance in adulthood.

Authors: *S. D. INIGUEZ[1], M. J. STONE[2], R. A. RODRIGUEZ[3], G. DAYRIT[3], L. F. ALCANTARA[4], B. L. WARREN[4], E. M. PARISE[4], K. N. WRIGHT[4], C. A. BOLAÑOS-GUZMAN[4]

[1]Psychology, Cal State San Bernardino, San Bernardino, CA; [2]Psychology, [3]California State Univ., San Bernardino, CA; [4]Psychology, Florida State Univ., Tallahassee, FL

Abstract: Epidemiological reports indicate that major depressive disorders (MDD) are common in children and adolescents. The prevalence of adolescent MDD has resulted in parallel increases in the prescription of fluoxetine (FLX) and related serotonin reuptake inhibitor antidepressants within this population. Although such treatments can last for years, very little is known about the long-term consequences of antidepressant exposure during developmental periods prior to adulthood on memory performance later in life. Thus, we exposed adolescent male c57BL/6 mice (postnatal day [PD] 35) to FLX (10 mg/kg, twice daily) for 15 consecutive days. We then assessed animals' behavioral performance on the Morris Water Maze spatial memory task when they reached adulthood (PD 70+). Specifically, mice were trained to find the location of a submerged escape platform on a single day task (8 training trials), and memory for the platform location was re-tested after a 24 hr delay (distance traveled and velocity). To increase the demands of the spatial task, the mice returned to the spatial task once again, 24hr later, and completed a probe trial (escape platform absent), and the time to reach the quadrant of the target platform location, as well as total time spent in the quadrant were recorded. We found that FLX exposure during adolescence did not influence spatial memory acquisition on the training day. In addition, no differences between the groups were observed when spatial memory was examined 24 hr after training. On the other hand, mice exposed to FLX during adolescence swam longer distances to reach the location of the missing platform, when tested 48 hr after training (probe trial). Our results suggest that as the demands of the spatial memory task increase, spatial memory deficiencies become apparent in adult mice exposed to FLX during adolescence. Overall, these results underscore the need for further research for a clearer understanding of the long-term functional effects of FLX exposure on the developing nervous system.

Title: SB 399885: 5-HT_6 receptor antagonist is efficacious in animal models of food addiction and craving

Authors: *D. SHANMUGANATHAN, B. KANCHARLA, P. JAYARAJAN, R. NIROGI
Suven Life Sci., Hyderabad, India

Abstract: Extensive research is being focused on the development of new pharmacological agents to control the food addiction/binge eating behaviour, which is commonly associated with bulimia nervosa, binge eating disorder and obesity. Hedonic properties of palatable food and addictive drugs are regulated by common brain substrates. 5-HT_6 receptor is involved in the central regulation of feeding and highly expressed in dopamine rich areas. In this study, the effect of 5-HT_6 antagonist on food addiction and craving was evaluated using palatable food induced binge eating and conditioned place preference task respectively. To investigate the role of 5-HT_6 receptor on glutamate mediated feeding control, effect of SB 399885 on dizocilpine induced hyperphagia was conducted. To rule out the nonspecific effects, behaviour satiety sequence was performed. SB 399885 significantly reduced the palatable diet consumption in binge eating rats and effectively blocked the expression of palatable food induced place preference. It significantly overturned the dizocilpine induced hyperphagia. SB 399885 reduced the frequency of eating behaviour without changing the other behavioural components of satiety sequence in rats. These results demonstrate that SB 399885 has potential to reduce the over-responsiveness to palatability through the enhancement of satiety signals and inhibition of palatable food induced craving. In conclusion, 5-HT_6 antagonism appears to be a useful pharmacological approach for the treatment of food addiction and associated disorders.

Title: A novel polymorphism (a378t) in the coding region of htph2 with unique effects on enzyme properties

Authors: *I. TEKIN[1], N. CARKACI-SALLI[1], M. C. BEWLEY[2], S.-S. SUNG[1], K. E. VRANA[1]
[1]Pharmacol., [2]Biochem. and Mol. Biol., Pennsylvania State Univ., Hershey, PA

Abstract: Tryptophan hydroxylase (TPH) catalyzes conversion of the aromatic amino acid tryptophan to 5-hydroxytryptophan, which is then converted to serotonin. Conversion of tryptophan to 5-hydroxytryptophan is the rate-limiting step in the biosynthesis of this neurotransmitter. The enzyme requires binding to iron in its ferrous form in order to be active. Recently, a single nucleotide polymorphism (rs78369038) in TPH2 coding region has been reported. Molecular modeling of the variant protein, A378T, suggests that replacement of the original alanine residue at position 378 with threonine prevents iron binding to the active site of the enzyme. Characterization of the effects of this SNP on TPH2 has been performed *in vitro* using recombinant protein. Radioenzyme activity assays showed that, this SNP causes disruption of activity of the enzyme. Disruption of iron binding seems to be due to occupation of the iron binding site by the relatively large side chain of threonine. This hypothesis has been tested via targeted mutagenesis of alanine at 378 into other amino acids with different structural properties (e.g. valine, glycine, methionine, and serine). Characterization of the protein bearing each of these mutations provides insight into the structural effects of these amino acid changes at the corresponding residue. The extent of iron binding for the different mutations remains to be determined.

Title: Variations in escitalopram's behavioral effects due to the presence or absence of an allosteric site on the serotonin transporter

Authors: *K. E. MURRAY[1], K. J. RESSLER[1,2], M. J. OWENS[1]
[1]Psychiatry and Behavioral Sci., Emory Univ., Atlanta, GA; [2]HHMI, Atlanta, GA

Abstract: Escitalopram, the S-enantiomer of citalopram, is a selective serotonin reuptake inhibitor (SSRI) that binds to the serotonin transporter (SERT) to inhibit serotonin uptake. In addition to its classic SSRI mechanism it has been shown that a second escitalopram molecule is also able to bind allosterically to a distinct site on the SERT. The effects of this allosteric site are not fully understood. It is hypothesized that this allosteric site may contribute to the efficacy of escitalopram, therefore the site is thought to be a potential site for future drug development to enhance SSRI action and to understand SERT function. This study uses novel transgenic mice with either a wildtype human SERT (hSERT-wt) transgene or an allosteric-null hSERT (hSERT-mut) to examine behavioral outputs of the presence or absence of the allosteric site. Previously wildtype C56Bl/6J were shown to have decreased time immobile in the tail suspension test (TST) with increasing escitalopram doses (> 10 mg/kg escitalopram oxalate) but this same effect was not observed in the transgenic lines on a 129Sv (Taconic) strain background. This study aims to identify if the loss of escitalopram's effects is due to the strain background or if a difference in the SSRI's interaction with the human transgenes rather than the wildtype mouse SERT. Transgenic mice of both hSERT-wt and hSERT-mut strains on a C57Bl/6J background are submitted to a 6 minute TST at weekly intervals for 6 weeks to complete a dose-response curve over 6 doses (0-32 mg/kg escitalopram oxalate, i.p.). A shift in the dose-response curve for behavioral outcome between the hSERT-wt and the hSERT-mut lines would indicate of a role for the allosteric site in the escitalopram-hSERT interaction. In particular, a rightward shift in the hSERT-mut mouse dose-response curve compared to the hSERT-wt mouse curve would indicate that the allosteric site enhances escitalopram's actions.

Title: Postnatal blockade of the 5-HT2A decreases aggression in monoamine oxidase A-deficient mice

Authors: S. C. GODAR, M. BORTOLATO, S. TAMBARO, F. LI, K. CHEN, *J. C. SHIH
Pharmacol Pharm Sci., USC, LOS ANGELES, CA

Abstract: Monoamine oxidase (MAO) A is the primary enzyme responsible for the metabolism of serotonin (5-HT) and norepinephrine (NE) in the brain. Although the role of MAO A in aggression and emotional reactivity is well-established, the molecular underpinnings of this link remain elusive. MAO A knockout (KO) mice exhibit overt aggressiveness and social deficits, as well as elevated levels of brain 5-HT, especially during early developmental stages. Previous data have shown that 5-HT2A receptors play a key role in the control of aggressive responses. In order to examine the role of early postnatal 5-HT2A activation in the aggressive responses exhibited by MAO A KO mice, we studied the changes in resident-intruder aggression in these animals after treatment with the 5-HT2 receptor antagonist ketanserin (3 mg/kg/day) during the first two weeks of postnatal life. MAO A KO mice treated with ketanserin during the first postnatal week exhibited a robust reduction of fighting duration and number of aggressive bouts, as well as a marked increase in the latency to the first attack. In view of the lack of specificity of ketanserin for 5-HT2A receptors, we tested our hypothesis with a parallel set of experiments, using a transgenic model of MAO A/ 5-HT2A double KO mice. Similarly to ketanserin-treated mice, 5-HT2A/MAO-A double KO mice exhibited a marked decrease in fighting behavior. These data collectively suggest that 5-HT2A hyperactivation in early stages are critical in the aggressive responsiveness and antisocial trait resulting from low or no MAO A activity in early developmental stages.

Title: Innovations on drug discovery of Alzheimer's and other CNS diseases: Phenotypic screening with *Drosophila* disease models

Authors: *I.-F. PENG[1], Y. ZHONG[2,3]
[1]Tsinghua University; Joekai Biotech, Kunshan City, China; [2]Cold Spring Harbor Labs., Long Island, NY; [3]Tsinghua Univ., Beijing, China

Abstract: In current drug discovery pipeline, in vitro biochemical and cell-based screening assays have been widely used before the pharmacological validation tests in in vivo animal models. Nevertheless, the low translation rate of drug candidates entering into in vivo systems impairs the pipeline progress in most CNS diseases with uncertain and/or complicated mechanisms. In parallel to those in vitro assays, we have developed several Drosophila CNS disease models as supplementary approaches. These animal models preserve behavioral deficits and pathological hallmarks similar to those observed in human patients, yet are low in running cost and are suitable for high-throughput screening expansions.
We have generated the fly Alzheimer's disease (AD) model through targeted expression of a transgene encoding a secretive form of human A-betaβ42 peptides in the Drosophila brain. Such expression leads to neurodegeneration with accumulation of A-beta 42, fibril deposits in the brain area, shortened life span, and severe age-dependent memory loss, which highly mimicking neuronal death and dementia syndromes in AD human patients. A computer-controlled massive screening system for olfactory learning assay has been developed on site, enabling high throughput screening studies for industrial needs. In our internal screening study of 5,000 compounds, we have identified >20 potential drug candidates for AD treatments. Interestingly, >50% of these candidates show potency on rescuing the memory loss in transgenic mice models. The toxicity and safety studies are carrying on to support further clinical studies in humans.
In addition to AD, we have also developed several other Drosophila disease models (Parkinson's disease, Schizophrenia, autism, Noonan syndrome, and neurofibromatosis type 1/von Recklinghausen disease) for drug discovery services.

Title: Two-photon microscopy reveals that astrocytes and microglia contribute to blood-brain barrier disruption by focused ultrasound

Authors: *A. BURGESS[1], T. NHAN[1,2], A. KEATING[3], K. HYNYNEN[1,2]
[1]Imaging Res., Sunnybrook Res. Inst., Toronto, ON, Canada; [2]Med. Biophysics, Univ. of Toronto, Toronto, ON, Canada; [3]Cell Therapy Program, Princess Margaret Hosp., Toronto, ON, Canada

Abstract: Focused ultrasound (FUS) has been used to successfully disrupt the blood-brain barrier (BBB), aiding in the delivery of therapeutic agents to the brain and leading to improvements in disease treatment. However, the mechanisms of BBB disruption and the microscopic effects of this disruption on resident brain cells are not well understood. In this study, we combine a custom-built ultrasound transducer with two-photon microscopy to conduct real time monitoring of BBB disruption in vivo. We have manufactured and tested a single element piezoelectric transducer with frequencies ranging from 1.15 to 1.30 MHz. Transgenic Wistar rats, expressing enhanced green fluorescent protein (EGFP), were anesthetized and a cranial window was made in the skull. The transducer, attached to a coverslip, was glued to the skull, covering the cranial window. Dextran-conjugated Texas Red (70 kDa) was injected intravenously. FUS (0.2-0.3 MPa estimated in situ pressure, 10 ms pulses, 1Hz pulse repetition frequency for a total duration of 120 s) was applied in the presence of preformed microbubbles. In vivo, we observed the retraction of astrocytic endfeet from the vessel wall at the onset of BBB disruption. Follow-up imaging (4-6 hours after initial BBB disruption) suggests that the endfeet are reattaching to the vessels and likely contributing to the functional recovery of the BBB. We also observed migration of EGFP-expressing glial cells towards disrupted vessels. Post-mortem immunohistochemistry was used to confirm these results. Real time, in vivo monitoring of FUS-induced BBBD will significantly enhance the understanding of the fundamental mechanisms and biological effects of this promising drug delivery technique.

Abstract: Primary tauopathies cause neurodegeneration, thought by misfolding and subsequent aggregation of protein Tau into oligomers and fibrils of unknown structure. Further aggregation yields neurofibrillary tangles in soma and neuropil threads in processes, as the argyrophilic markers for post-mortem pathological diagnosis. In Alzheimer's disease (AD), tauopathy is proposed to be secondary to, but co-diagnostic with amyloid pathology, while respective contributions to clinical course and final dementia remains open for analysis and debate. Therapeutic approaches have yet to prove specificity and efficacy, emphasizing the need for additional treatment options. Immunotherapy is emerging in pre-clinical studies as a promising approach for clearing misfolded proteins, despite the fact that protein Tau is mainly an intra-cellular target. Consequently, thorough preclinical assessment of Tau-based immunotherapy is instrumental to prove potential, but above all safety.
We analyzed efficacy and safety of newly generated phospho-peptides embedded in synthetic liposomes as Tau-targeted vaccines in Tau.P301L and bigenic Tau.P301LxGSK3b mice (biGT) mice, validated pre-clinical models (Terwel et al, 2005, 2008). Liposome-based vaccines were essentially prepared as for amyloid peptides (Muhs et al, 2007) to display synthetic phospho-peptides that cover important "patho-topes" of Tau. Injection into wild-type and transgenic mice elicited robust and stable antisera responses against phosphorylated peptides already after 2 immunizations. The polyclonal antisera specifically detected tauopathy in brain sections of biGT mice with proven tauopathy (Terwel et al., 2008), labeling neurofibrillary tangles and neuropil threads in hippocampus and cortex, and corroborated biochemically by western blotting. Specific ELISA demonstrated high and stable antibody titers against synthetic phospho-Tau-peptides as opposed to negative reaction with non-phosphorylated Tau-peptides. Neuro-inflammatory reactions or other negative side-effects were not observed in brain of transgenic mice after long-term regimes of vaccination. Re-stimulation of splenocytes from immunized mice with corresponding phospho-Tau peptides did not trigger more secretion of IFN-g or IL-4 than from naive splenocytes. After 3 months, immunized Tau.P301L mice presented with improved survival, delayed motor-impairment, reduced loss of body-weight and decreased phospho-Tau isoforms in brain.
The data corroborate the premise that liposome based phospho-Tau peptide vaccines have considerable potential as safe treatment option for Tau-mediated neurodegenerative diseases.

Title: Small molecules can rescue progranulin haploinsufficiency underlying frontotemporal lobar degeneration caused by GRN mutations

Abstract: Frontotemporal lobar degeneration (FTLD) is a dementia-type as frequent as Alzheimer's disease in patients under 65. FTLD encompasses a range of neurodegenerative disorders with predominant neuronal loss in the frontal and temporal lobes. The most common cause of familial FTLD are mutations in the progranulin gene (GRN). Patients with GRN mutations have reduced GRN levels in cerebrospinal fluid and blood and GRN haploinsufficiency is thought to be the underlying pathogenic mechanism. In line with the neurotrophic properties of progranulin, pharmacological enhancement of GRN transcription holds a promising therapeutic strategy for FTLD caused by GRN mutations.
An unbiased high-throughput wet-lab screen using a neuro2a cell line in which luciferase expression is driven by a GRN promoter fragment found several compounds that induce an upregulation of luciferase signal. After initial hit confirmation, an in silico analogue search was

performed to identify additional small molecules structurally similar to the hits of the wet-lab screen. Compounds with confirmed GRN-upregulating capacity were further tested in fibroblasts from patients with a GRNIVS1+5G>C mutation and controls. Several small molecules were confirmed to increase GRN production and secretion by transcriptional enhancement in primary human fibroblasts. The reduced GRN mRNA and protein levels in primary cells of patients carrying a GRN loss-of-function mutation were completely restored to normal levels by these compounds.
Our data show that small molecules are capable to overcome GRN-deficiency caused by heterozygous loss of function mutations in GRN.

Title: Cellular characterization of histone deacetylase (HDAC) inhibitors

Authors: *R. MÜLLER, H. MACK, M. VAN GAALEN, V. LAKICS
Abbott Gmbh & Co. KG, Ludwigshafen, Germany

Abstract: Members of the histone deacetylase (HDAC) family of proteins are widely known for their epigenetic function controlling gene transcription, and they are also reported to be involved in the regulation of the tubulin cytoskeleton and macromolecular breakdown. These processes have important physiological roles and their perturbation has also been linked to cancer and Alzheimer’s disease. In the current study, the effects of selective and pan-HDAC inhibitors were investigated in various pre-clinical model systems.
To study two different functions of HDACs in a cellular environment, we have measured tubulin acetylation by HDAC6 and the acetylation of histones by class I HDACs (e.g. HDAC1/2) in the human cell line NTera2 and also in rat primary neurons. Antibodies against acetylated histone 3 and 4 as well as acetylated tubulin were used in Western blot and immunofluorescence-based high-content analysis. First, the cellular potency and selectivity of a pan-HDAC inhibitor (SAHA), as well as inhibitors reported to be HDAC1/2 specific (CI-994, BRD-6929) or HDAC6 specific (tubastatin A, tubacin) were established. In addition, the effect of tubastatin A and

tubacin on tubulin acetylation and cell death were investigated in primary neurons challenged with different excitotoxins.
SAHA efficiently increased H3 and H4 acetylation both in NTera2 cells and in primary neurons reaching statistically significant effects at a concentration of 1µM. In NTera2 cells, SAHA also increased levels of acetylated tubulin with a similar potency. CI-994 and BRD-6929 affected histone but not tubulin acetylation confirming their selectivity against HDAC6. They were slightly less potent compared to SAHA. Tubastatin A and tubacin mainly affected tubulin acetylation inducing statistically significant changes at 0.1µM and 1µM, respectively. Interestingly, at high concentrations (10µM) these agents also strongly enhanced histone acetylation albeit the considerable cell loss induced likely confounds interpretation of these effects. Treatment of primary neurons with different excitotoxins resulted in cell death and a marked reduction of tubulin acetylation indicative of cytoskeletal damage. SAHA, tubastatin A, and tubacin reversed the de-acetylation, but were unable to protect against the neurotoxicity.
In summary, using Western blot and high-content analysis we have characterised the potency and selectivity of HDAC inhibitors in different cellular environments. These values were very similar in the neuronal cell line NTera2 and in rat primary neurons. Reported neuroprotective effects of HDAC inhibitors against oxidative damage could not be extended to excitotoxic injury.

Title: Stabilisation of hydrogels containing neural cells to form CNS tissue models for monitoring neuronal and glial cell behaviour *in vitro*

Authors: C. O'ROURKE[1], J. LOUGHLIN[1], R. DRAKE[2], *J. B. PHILLIPS[1]
[1]Open Univ., Milton Keynes, United Kingdom; [2]TAP Biosystems, Hertfordshire, United Kingdom

Abstract: Recreating the 3D environment of the CNS using hydrogel matrices allows neurons and glial cells in vitro to behave similarly to their counterparts in vivo, providing a relevant tool for neurobiological studies. The overall aim is to develop engineered neural tissue models to resemble functional CNS tissue, with anisotropic tracts of neurons and glia arranged within a hydrogel, at a scale suitable for drug screening. Stability of cellular hydrogels is important for the generation of engineered tissue models and our approach employs RAFT™ technology (TAP Biosystems) that removes some interstitial fluid, increasing matrix density to stabilise the architecture of the hydrogels. In order to develop a robust CNS tissue model using this method, it was necessary to assess the sensitivity of neural cells to the stabilisation process. Initial experiments used C6 glioma cells seeded within collagen gels which were then subjected to RAFT for 15 min. Cell viability was assessed by propidium iodide staining in control constructs with no treatment and in RAFT-treated constructs at time points of 24 and 72 hours. Results demonstrated that the RAFT process did not reduce cell viability when compared to controls. After 24 hours, 0.58 ± 0.14 % cell death was seen in the treated constructs and 1.38 ± 0.26 % was viewed in controls. After 72 hours, a similar pattern was observed with cell death of 0.33 ± 0.06 % in treated and 1.80 ± 0.27 % in controls. Following initial tests with C6 glioma cells, subsequent experiments used the same approach to assess the viability of a range of primary rat CNS neural cells and other relevant cell lines including astrocytes, oligodendrocytes, microglia and neurons. CNS co-culture systems will incorporate various combinations of cells that can be tailored to suit specific neuroscience research requirements and assessing the viability of cells is a critical step in the development of culture models. Stabilisation of the cellular hydrogels through increasing the cell and matrix density in this way will be used to establish versatile engineered neural tissues. A consistent model system will provide experimental platforms to monitor neural cell morphology, proliferation, differentiation and sensitivity, as well as neuron-glial interactions to generate rapid, reliable and reproducible results.

Title: Autophagy enhancers as potential therapeutics for neurodegenerative diseases: using a flow cytometry based assay to monitor autophagy flux

Authors: *W. SHEN, S. HALLOWELL, K. L. PAUMIER, L. LI, P. LOOS, D. GEBHARD, R. DOYONNAS, A. F. STEPAN, T. T. WAGER, J. DUNLOP, W. D. HIRST, Z. BERGER

Abstract: Macroautophagy (referred to here as autophagy) is a lysosome-dependent degradation mechanism. Although autophagy was initially identified as a starvation response, it plays critical roles in many biological processes, including degradation of damaged organelles, misfolded proteins and protein aggregates. As the aggregate-prone mutant proteins, such as mutant α-synuclein and huntingtin, play a prominent role in the pathogenesis of various neurodegenerative disorders, it has been hypothesized that an increase in autophagy could represent a potential therapeutic strategy for these diseases. Thus, it is of increasing interest to identify novel mechanisms that enhance autophagy as therapeutic targets for neurodegenerative diseases. Many conventional assays, such as GFP-LC3 based image analysis do not distinguish autophagy enhancers from blockers, as the accumulation of autophagosomes can result either from an increase in the formation or a decrease in the clearance of autophagosomes. Therefore it is critical to develop a reliable assay that measures autophagy flux.
Here we describe a flow cytometry based assay to monitor autophagy flux in vitro. We generated a monoclonal, inducible cell line that expresses GFP-SQSTM1/p62 fusion protein upon addition of doxycycline. SQSTM1/p62 (referred to as p62) is a ubiquitin-binding protein that targets ubiquitinated proteins for degradation by autophagy; p62 itself is also degraded in this process. We examined this degradation of GFP-p62 in response to known small molecule autophagy modulators and found that autophagy enhancers such as rapamycin and PI-103 increase the rate of degradation of GFP-p62, whereas the autophagy inhibitor Bafilomycin A1 had the opposite effect. We also tested the effect of siRNA knock-down of several autophagy regulatory genes on the degradation of GFP-p62. siRNA knock down of mTOR decreased the accumulation of GFP-p62, while knock down of ULK1 increased the GFP-p62 abundance. Our data suggested that this GFP-p62 based assay measures the autophagy flux and discriminates autophagy enhancers from blockers. In summary, these results, suggest that this GFP-p62 based flow cytometry assay can be adapted for moderate to high throughput compound or genome-wide siRNA screen for autophagy enhancers and inhibitors.

Title: The role of histone deacetylase inhibitors in the mitigation of type 2 diabetes-mediated cognitive deterioration: Implications for alzheimer's disease therapy

Authors: *G. M. PASINETTI
Mount Sinai Sch. of Med., New York, NY

Abstract: Our laboratory recently demonstrated that epigenetic chromatin modifications associated with type-2 diabetes (T2DM) may play a role in brain pathophysiology in neurodegenerative disorders. We previously discovered that there are significant changes in the expression of select chromatin modification enzymes, such as histone deacetylases (HDACs), in the brains of T2DM subjects compared to control subjects, and that these changes coincide with altered expression of proteins involved in synaptic function, such as PSD95 and synaptophysin. We hypothesized that T2DM may induce epigenetic modifications associated with increased susceptibility to Alzheimer's disease (AD)-type neurodegeneration. Using a mouse model of diet-induced T2DM, we found that, similar to humans, T2DM mice showed differential expression of epigenetic-modifying enzymes in the brain compared to controls. In particular, we found significant up-regulation of HDAC class IIa, including HDACs 4, 5, and 9, in the brains of diabetic mice. These alterations coincided with increased susceptibility to oligomeric Aβ (oAβ) induced synaptic toxicity and oAβ-induced synaptic dysfunction, as assessed by long term potentiation (LTP). Most interestingly, we found that inhibition of class IIa HDACs using an HDAC IIa-specific inhibitor, MC1568, increased transcription levels of PSD95 and synaptophysin in primary neuron cultures from C57Bl6/J mice and prevented LTP deficits found in old-T2DM mouse ex vivo hippocampal slices. The studies provide much-needed information regarding mechanisms underlying potential risks posed by diabetes in terms of diminishing cognitive function and may provide the basis for strategies aimed at early primary prevention against key risk factors for AD. This work was supported by discretionary funding to GMP.

Title: Inhibition of GCPII for the treatment of cognitive impairment in multiple sclerosis

Authors: *K. RAHN[1], C. WATKINS[1], J. ALT[2], R. RAIS[1], M. STATHIS[2], I. GRISHKAN[1], C. CRAINICEAU[1], M. POMPER[1], C. ROJAS[2], P. CALABRESI[1], J. BRANDT[1], P. BARKER[1], B. SLUSHER[2], A. KAPLIN[1]
[1]Johns Hopkins Univ., Baltimore, MD; [2]Johns Hopkins Brain Sci. Inst., Baltimore, MD

Abstract: Cognitive impairment is a frequent comorbidity of multiple sclerosis (MS), but no treatments exist to target this aspect of disease. Human magnetic resonance spectroscopy data collected from MS patients demonstrated significant positive correlations between hippocampal N-acetyl aspartyl glutamate (NAAG) levels and performance on a battery of cognitive tests. Therefore, we hypothesized that pharmacological upregulation of NAAG, a peptide that is converted to N-acetyl aspartate and glutamate by the enzyme glutamate carboxypeptidase II (GCPII), would be an efficacious method of reversing cognitive impairment in MS. Using an animal model of MS (experimental autoimmune encephalomyelitis, EAE) and Barnes maze and fear conditioning behavior tests, we measured cognitive performance following chronic treatment of the GCPII inhibitor 2-PMPA. While disability levels (i.e. severity of paralysis) were unaffected due to the 2-PMPA treatment, two independent experiments confirmed that 2-PMPA-treated mice exhibited a significant improvement in Barnes maze and fear conditioning performance compared to vehicle-treated EAE controls. Post-mortem analysis revealed that the 2-PMPA can penetrate the blood brain barrier and that treatment significantly increases NAAG levels in the brains of these mice. In summary, these data support inhibition of GCPII for the treatment of cognitive impairment in MS.

Title: Ginsenoside Rg1 increase neurogenesis and synaptogenesis *in vivo* and *in vitro*

Authors: *J. ZHANG
Pharmacol., Inst. of Materia Medica,Chinese Acad. of Med. Sci., Beijing, China

Abstract: Basic and clinical study of Alzhemier's disease showed that senile plaques and Neurofibrillary tangles are not related to the degree of cognitive impairment. Neuro-synapse loss suspended signal delivery and signal transduction leading to neuropsychological dysfunction and memory disruption which was considered as the main pathological feature of Alzheimer disease. Thus the new strategies for prevention and treatment of dementia were increasing neurogenesis and synaptogenesis. Ginsenoside Rg1 isolated from ginseng was shown to improve learning and memory in 10 models of memory impairment. In anesthetized and freely moving rats, Rg1 could increase synaptic plasticity in both efficacy and structure. The latter is mainly to increase synapse density and dentritic spine density significantly. Their mechanism maybe due to the increase of intracellular calcium concentration and polymerization of F-actin. Furthermore, Rg1 increased hippocampal neurogenesis in vitro and in vivo, under physiological and pathological circumstances. NMDA receptor and iNOS are involved in the effect of Rg1 on increasing neurogenesis. Above mentioned findings suggest that ginsenoside Rg1 can be used for treatment of dementia and many kinds of memory impairment.

Title: Water restriction enhances chorda tympani responses to NaCl and KCl in rats

Authors: *T. G. MAST, J. A. KOSTANSEK, S. M. KELLY, R. J. CONTRERAS
Dept. of Psychology, Florida State Univ., TALLAHASSEE, FL

Abstract: Our overall goal is to uncover salt-taste coding mechanisms. Here we investigated the effect of water restriction on the two different salt detection mechanisms present in the rat chorda tympani (CT) nerve. The first mechanism is dependent upon the epithelial sodium channel (ENaC), is blocked by benzamil, and is specific to the cation sodium. The second mechanism, while undefined, is independent of ENaC, and detects multiple cations. In nature, water is present as a low-salt solution, thus we hypothesized that water restriction would differentially modulate the two salt-sensing mechanisms in the CT to maximize detection of low-salt solutions. Specifically, the benzamil-insensitive CT fibers would have enhanced responses to hypertonic and reduced responses to hypotonic solutions; while benzamil-sensitive fibers would have enhanced responses to sodium solutions due to mechanistically increasing the benzamil-sensitive ENaC. We recorded CT whole nerve electrophysiological activity in response to lingual application of NaCl (30, 75, 150, 300, 500, and 600 mM), of KCl (30, 75, 150, 300, 500, and 600 mM) and of artificial rain in control and 24hr water-restricted male rats (n = 7, each). All stimuli were presented in artificial saliva and before and after lingual application of 5μM benzamil. The low-salt stimulus, artificial rain, did not excite the CT. Water restriction significantly enhanced the integrated CT responses to NaCl, $F(1,42)=10.8$, $p=0.002$, but not to KCl $F(1,42)=1.9$, $p=0.18$. The two salt-sensitive mechanisms each had enhanced responses to NaCl; benzamil-sensitive, $F(1,42)=14.9$, $p=0.0004$, and the benzamil-insensitive, $F(1,42)=4.6$, $p=0.04$, respectively. Surprisingly, the sodium-specific benzamil-sensitive pathway_and not the generalist benzamil-insensitive pathway_had enhanced KCl responses, $F(1,42)=15.8$, $p=0.0003$. Normalizing the CT responses to ammonium chloride slightly altered these effects. Thus, deprivation significantly alters CT responses to NaCl and KCl salts and the magnitude of this effect can be lost when the integrated signal is normalized to a third cation, ammonium chloride. Future experiments will investigate the roles, if any, that osmotic and volemic thirsts play in modulating CT responses to salts.

Title: Differences between cerebral activation of analgesia by sucrose and an artificial sweetener in humans

Authors: *Y. NAKAMURA[1], T. K. GOTO[2], K. TOKUMORI[3], K. KOBAYASHI[4], K. YOSHIURA[3]
[1]Fukuoka, Japan; [2]The Univ. of Hong Kong, Hong Kong, China; [3]Kyushu Univ., Fukuoka, Japan; [4]Kyushu Univ. Hosp., Fukuoka, Japan

Abstract: Intraoral infusion of sweet taste produces analgesia in adult humans (sweet taste-induced analgesia; SIA) (Kakeda 2010). However, few studies have investigated brain activation associated with SIA (Kakeda et al. 2010). To our knowledge, there is no information on how artificial sweeteners induce SIA in human brain. The aim of this study was to examine the differences between cerebral activation of SIA by sucrose and that by an artificial sweetener, using 3-T functional magnetic resonance imaging (fMRI).
The Human Experimentation Committee of Kyushu University approved all experimental procedures. Seven males and seven females (aged 22-33 years) participated in this study. Sucrose solution [24% (w/v)] and the solution of an artificial sweetener (Palsweet^{TM}) [8% (w/v)] were used for generating the sweet condition, while artificial saliva (25 mM KCl with 2.5 mM $NaHCO_3$) was used as the control solution. Sweet and control solutions were alternately applied to the participant's mouth for 20 sec. The participants were subjected to the cold pressure test which involved applying an ice pack onto the participant's dorsum manus for 20 sec. During fMRI scanning, participants underwent 5 events: "Sucrose", "Sucrose + Pain", "Palsweet", "Palsweet + Pain" and "Pain + control." Each event was repeated 12 times randomly. The ice pack was applied to alternate hands in each pain event. Participants pressed a button with their non-stimulated hand when they began to feel the pain. Cerebral activation of SIA by sucrose and Palsweet was compared in four contrasts: "Sucrose + Pain" - "Pain + control", "Palsweet + Pain" - "Pain + control", "Sucrose + Pain" - "Palsweet + Pain" and "Palsweet + Pain" - "Sucrose + Pain". An anatomical mask was applied on the statistical maps involving the taste and pain pathways.
Cerebral activation of SIA by sucrose was observed in the right putamen [$P < 0.05$ $FWE_{\text{-corrected}}$ with small volume correction (SVC)]. Cerebral activation of SIA by Palsweet was observed in the left postcentral gyrus, the left ACC, and the right rolandic operculum ($P < 0.05$ $FWE_{\text{-corrected}}$ with SVC). No significant neural activation was observed in "Sucrose + Pain" - "Palsweet +

Pain" contrast, whereas neural activation in the right rolandic operculum was detected in "Palsweet + Pain" - "Sucrose + Pain" contrast ($P < 0.05$ $FWE_{-corrected}$ with SVC).
Cerebral activation of SIA by sucrose was observed in the putamen, which is a dopaminergic area related to the behavioral pleasantness response, whereas in "Palsweet + Pain" - "Sucrose + Pain" contrast, neural activation was observed in the pain pathways, possibly suggesting that the effect of SIA by sucrose is more significant than that by Palsweet.

Title: A common interoceptive and gustatory representation in the human insula.

Authors: *J. AVERY, K. L. KERR, J. C. BARCALOW, J. BODURKA, W. K. SIMMONS
The Laureate Inst. for Brain Res., Tulsa, OK

Abstract: The dorsal mid-insula is the location of primary gustatory cortex in the human brain. It receives direct afferent input from the gustatory nucleus of the thalamus, and numerous neuroimaging studies implicate this region in gustatory processing. The dorsal mid-insula also underlies interoceptive awareness (i.e., the awareness of internal body sensations). Visceral afferents are relayed through the nucleus of the solitary track, to the ventroposteromedial nucleus of the thalamus, before terminating in this region of the insula, and neuroimaging studies demonstrate activation of this region during tasks involving interoceptive attention. Two separate studies by our lab, one requiring focal interoceptive attention, and the other requiring passive gustatory stimulation, have found overlapping areas of activation in the insula during these disparate tasks. The apparent overlap could result from differences in insula organization among the two groups of subjects. It could also, however, reflect a common neural representation in the insula shared by both interoception and gustation, and idea that finds support in rodent electrophysiological studies that have identified insular neurons that respond to both taste and interoceptive stimulation. To date, however, there is no evidence for a common interoceptive-

gustatory representation in human insula. To assess this possibility, we asked healthy volunteers between the ages of 18 and 40 years to undergo fMRI while perform tasks involving interoceptive attention to visceral sensations as well as a “Gustatory Mapping” task using an MR compatible tastant delivery system. Imaging was conducted with a 3T MRI scanner and a 32-element receive-only brain surface coils array which granted superior image quality at high spatial resolution. Group conjunction analyses revealed overlapping patterns of activation for both tasks in bilateral regions of mid to posterior insular cortex. The identified regions were selectively responsive to visceral interoceptive attention and also exhibited strong responses to sweet versus neutral tastants. This observed overlap within the insula suggest the possibility that either gustation and interoception share some functional property to which the neurons within these regions are sensitive, or that neurons selective for gustation and interoception are intermingled in this region of the human insula and do not share a distinct topographic organization.

Title: Differences in the motivational efficacy of sucrose in sucralose preferring and avoiding rats

Authors: *G. C. LONEY, C. LOPEZ, C. LAMBRIGHT, L. A. ECKEL
Dept. of Psychology, Florida State Univ., TALLAHASSEE, FL

Abstract: Individual variation in the preference for, and consumption of, artificial sweeteners is often indicative of differential responding aimed at obtaining motivational stimuli. For instance, rats bred for a phenotypic difference in their baseline saccharin intake display similar differences in self-administration of sucrose, morphine and cocaine. Rats also display an innate phenotypic difference in their preference for sucralose. We have previously shown that rats can be classified as sucralose preferrers (SP) or sucralose avoiders (SA) based on their consumptions of sucralose and water during 2-bottle preference tests. This avoidance has been attributed to the fact that SA and SP perceive the taste of sucralose as qualitatively different. While SA generalize the taste of

sucralose to that of both sucrose and quinine, SP generalize the taste of sucralose solely to that of sucrose. This suggests that SA perceive a bitter side-taste in sucralose to which SP are relatively insensitive. This behavioral avoidance generalizes to saccharin as well as sucrose solutions adulterated with increasing concentrations of quinine. Here we investigated whether SA and SP differ in their operant responding for sucrose pellets as measured by differences in breakpoint responding in a progressive-ratio (PR) lever-pressing task. SA and SP were autoshaped to lever press for 45 mg sucrose pellets and advanced through a fixed-ratio (FR) 1, 3, 5 and 8 schedule of reinforcement before continuing to a PR schedule where the rats received daily saline injections. As the dopaminergic system has been implicated in the perceived rewarding efficacy of sucrose, after completion of the baseline PR schedule, rats were injected with 100, 200 and 300 μg/kg of the selective D2 receptor antagonist raclopride followed by 25, 50 and 100 μg/kg of the selective D1 receptor antagonist SCH 23390 (both presented in ascending order). Each drug concentration was administered at least 48 h after the previous concentration. On average, SP showed a higher breakpoint for sucrose responding under baseline saline conditions relative to SA (43.2 ± 9.6 vs. 29.3 ± 7.6, respectively). Statistical analyses revealed that both drugs except the lowest concentration of SCH 23390 were efficacious in reducing breakpoint responding for sucrose pellets (Ps < 0.01). No group differences in response to either drug were obtained using these concentrations. These findings demonstrate that rats differing in their taste perception of sucralose also differ in their operant responding for sucrose pellets under baseline conditions suggesting a difference in the motivational saliency of sucrose in these same rats.

Title: CALHM1 constitutes a conduit for cellular ATP release and mediates sweet and bitter taste perception

Authors: A. TARUNO[1], A. LI[1], Z. MA[1], P. MARAMBAUD[2], I. MATSUMOTO[3], M. M. CIVAN[1], M. G. TORDOFF[3], *K. FOSKETT[1]

Abstract: Calcium homeostasis modulator 1 (CALHM1) was discovered as a gene expressed throughout the brain and linked to Alzheimer's disease. Subsequent studies demonstrated that CALHM1 was a pore-forming subunit of a novel ion channel regulated by membrane voltage and extracellular Ca^{2+}, with a pore diameter large enough to allow permeation of small molecules up to 1 kD. Here, we have found that expression of CALHM1 induces a novel ATP permeability that releases ATP into the extracellular medium in response to maneuvers that activate the CALHM1 ion channel. CALHM1-mediated ATP release is insensitive to blockers of other putative ATP release channels and to inhibition of vesicular trafficking. CALHM1 is expressed in type II taste receptor cells that respond to sweet and bitter tastes by non-vesicular release of ATP as an essential neurotransmitter to afferent gustatory nerve fibers. Voltage-gated CALHM1 ion currents were recorded specifically in type II cells. *CALHM1* knockout mice lack the ion currents, do not release ATP from taste receptor cells in response to taste solutions, and are indifferent to bitter and sweet tastes. Thus, CALHM1 provides a missing link in taste perception, connecting signal transduction at the taste receptors and generation of action potentials to activation of afferent gustatory neural pathways. Other CALHM isoforms might also be involved in taste. They and CALHM1 may participate in physiologically important ATP release in other cell types. CALHM1 is a voltage-gated ion channel that mediates ATP release in taste buds as an essential mechanism of sweet and bitter taste transduction. Accordingly, CALHM1 is an appealing target for studying taste physiology.

Title: Characterization of rostral nucleus of the solitary tract neuron populations involved in oromotor reflexive circuitry

Authors: *J. A. CORSON[1], R. M. BRADLEY[2]
[2]Biologic and Materials Sci., [1]Univ. of Michigan, Ann Arbor, MI

Abstract: The efferent circuitry of the first-order gustatory nucleus, the rostral nucleus of the solitary tract (rNST), arises from two major pathways. Although much is known regarding the characteristics of ascending projections to the pons, the biophysical, morphological, and synaptic properties of the intramedullary descending projection neurons remains unstudied. To identify rNST descending projection neurons, iontophoretic injections of DiI were made into the reticular formation (the major target of this neuron population). One to three days post-injection, 300-400μm coronal or parasagittal (parallel to the solitary tract) brain slices containing the rNST were prepared for whole cell patch clamp recording. Most neurons (62%) responded to depolarizing current injection with a tonic firing pattern, while approximately 23% responded with an initial burst of action potentials followed by a steady-state depolarized plateau. Descending projection neurons also exhibited a number of different voltage activated currents, with some neurons expressing post-inhibitory rebound spikes, Ih currents, and A-type potassium currents. Synaptic connectivity with primary afferents was tested in a parasagittal plane of section developed to include the solitary tract, primary afferent terminal field, and projection neurons within a single 400μm slice. Small current pulses delivered to the rostral tip of the solitary tract with a bipolar stimulating electrode evoked monosynaptic excitatory post-synaptic currents in approximately half of the neurons. The remainder responded with postsynaptic currents with variable latency and reliability, indicative of polysynaptic connections. Pharmacological blockade of glutamate receptors revealed that monosynaptic responses were largely AMPAergic with only a minor NMDA component. The majority of neurons recorded were multipolar with dendrites extending into several rNST subdivisions. In contrast to other cell populations in rNST, descending projection neuron dendrites were often covered in spines, suggesting synaptic plasticity in the gustatory brainstem reflex circuitry. Individual axons were also visualized, constituting the first examination of single cell axonal morphology in the rNST for any cell population. This examination revealed that descending projection neurons often exhibit intra-rNST axon collaterals and boutons, suggesting a contribution of these neurons in intra-rNST circuits.

Title: Glossopharyngeal transection alters oil intake in food or water deprived rats.

Authors: *H. FOO, E. HANDLY, N. HORVATH, R. NORGREN
Neural and Behavioral Sci., Pennsylvania State Univ. - Col. of Med., Hershey, PA

Abstract: Recent evidence suggests that taste buds within the circumvallate papillae are responsible for the detection of fat. Taste buds in the posterior lingual papillae (circumvallate and foliate) are innervated by the glossopharyngeal (GL) nerve. We tested the effect of bilateral transection of GL (GLX) on intake of 0.3 M sucrose, 4.8%, 16%, and 100% oil emulsions during *ad libitum* food and water, food restriction, or water deprivation. The stimuli were available semi-randomly interspersed with water trials. All trials were 10 sec with an average 5 sec intertrial interval. Under *ad libitum* conditions, Sham and GLX rats licked sucrose the most, followed by oil emulsions in a concentration-dependent manner (100% > 16% > 4.8%). Transection of the GL nerves did not affect the amount of sucrose or oil consumed. When food deprived, Sham rats lost their concentration-dependent intake of 16% and 100% oil. They consumed the same amount of 16% and 100% oil as 0.3 M sucrose. In contrast, the intake of the GLX rats did not change from the *ad libitum* condition, i.e. sucrose > 100% > 16% > 4.8% oil emulsions. When water deprived, Sham and GLX rats lost their concentration dependent intake of oil. Nevertheless, the GLX rats consumed less 100% oil than Sham rats. Thus, denervating the gustatory and somatosensory receptors of the posterior oral cavity does not eliminate oil intake but under some circumstances flattens the concentration response function.

Title: Differential distribution of AgRP and POMC in taste buds of mice

Authors: S. H. MONAHAN, S. T. HENTGES, *L. M. STONE
Colorado State Univ., Fort Collins, CO

Abstract: Circuits in the oral cavity, digestive system and central nervous system work together to maintain homeostatic balance between nutrient intake and energy expenditure; a key component of these circuits is the ability to determine the nutritional status of the body. Disruption of the circuits can lead to obesity and associated diseases. In taste buds, changes in the palatability of foods due to changes in taste receptor responses may contribute to obesity. Recent studies indicate that hormone and peptide receptors are present in subpopulations of taste cells and activation of these receptors leads to changes in taste sensitivity (for review see Niki et al., 2010). These proteins are also found in the arcuate nucleus of the hypothalamus, in two main opposing circuits that regulate energy balance. Activation of the first circuit results in an increase in feeding. Cells within this orexigenic circuit express neuropeptide Y (NPY) and agouti gene-related peptide (AgRP). The opposing circuit is anorexigenic and contains cells that express proopiomelanocortin (POMC) and cocaine- and amphetamine-regulated transcript (CART). Nutritional signals such as glucose, fatty acids and hormones influence these neurons and lead to changes in feeding behavior and energy balance. Previous studies indicate that taste receptor cells express NPY (Zhao et al., 2005) and receptors for endocannabinoids and leptin receptors (for review see Niki et al., 2010). In the current study, we show that taste cells express AgRP and POMC. Subpopulations of taste cells that exhibit immunoreactivity (ir) for AgRP are present in circumvallate and foliate taste buds, but not in fungiform taste buds. In addition, although AgRP and the G protein α-gustducin are co-expressed in some taste cells, T1R3 positive taste cells do not appear to express AgRP-ir. This suggests that AgRP expression is associated with bitter sensitive taste cells rather than cells sensitive to sweet and umami stimuli. Taste buds from POMC-GFP mice exhibit GFP-ir indicating that POMC peptides may also be expressed in taste buds. POMC-GFP is present in both gustducin-ir cells and in cells that lack gustducin. In summary, taste receptor cells express peptides that are involved with maintaining energy homeostasis in the hypothalamus. Taste cells expressing these peptides also may have roles in regulating energy balance by affecting food palatability. Future experiments will investigate the relationship between taste cells expressing POMC and AgRP to determine whether these relationships are similar to, or different from, those between POMC and AgRP expressing cells in the hypothalamus.

Title: Differential effects of electrical stimulation of the central amygdala and lateral hypothalamus on taste reactivity behaviors in conscious rats

Authors: *M. S. KING, C. A. RILEY, N. K. NAGRANI
Dept Biol, Stetson Univ., DELAND, FL

Abstract: Taste reactivity (TR) behaviors are controlled by brainstem gustatory structures including the rostral nucleus of the solitary tract (rNST), parabrachial nucleus (PBN), and medullary reticular formation (RT). Several forebrain structures including the central amydgala (CeA) and lateral hypothalamus (LH) are inter-connected with brainstem gustatory nuclei and have been shown to modulate the electrophysiological responses to taste inputs within the rNST and PBN. The current study investigated the behavioral effects of electrical stimulation of the CeA and LH in conscious rats. Stainless steel electrodes were implanted into the CeA or LH of 60 male Wistar rats using a stereotaxic device. During the same surgical session intra-oral cannulas were implanted. After a one-week recovery/adaptation period the CeA or LH was electrically stimulated (0.4 ms duration, 50 Hz, 0.1-0.2 mA) for 5 min while TR behavioral responses were videotaped. During the stimulation period, 4 rats in each group received an intra-oral infusion (0.233 ml/min) of either NaCl (0.1M), sucrose (0.1 M), HCl (0.03 M), quinine HCl (0.003 M) or nothing. In the absence of taste stimuli, both CeA and LH stimulation elicited ingestive, but not aversive, TR behaviors. LH stimulation decreased ingestive TR behaviors caused by NaCl (by 72%), sucrose (by 62%), HCl (by 62%), and quinine HCl (by 79%), and aversive responses to quinine HCl (by 80%). On the other hand, CeA stimulation did not alter ingestive behaviors to any tastant tested but increased the aversive responses to NaCl (by 24-fold) and HCl (by 3.5 fold). To investigate potential neural mechanisms underlying these behavioral effects, the numbers of Fos-immunoreactive (Fos-IR) neurons in the rNST, PBN, and RT were counted. One hour after TR behaviors were videotaped, the rats were sacrificed, perfused, and their brains processed for Fos-IR. CeA and LH stimulation differentially affected

neuronal activity as indicated by the numbers of Fos-IR neurons in brainstem gustatory structures. CeA stimulation increased Fos-IR neurons within the rNST, PBN, and parvocellular RT during NaCl infusion while LH stimulation increased Fos-IR neurons in the rNST (particularly the ventral and lateral subdivisions) or the RT to each tastant tested. In sum, electrical stimulation of either the CeA or LH in conscious rats elicited ingestive TR behaviors but LH stimulation generally decreased TR responses to oral infusion of all tastants while CeA stimulation increased aversive responses to NaCl and HCl. These behavioral responses may be explained in part by the differential effects of CeA and LH stimulation on neural activity in gustatory brainstem nuclei.

Title: Intra-laminar connections in supragranular mouse core auditory cortex show functional anisotropy

Authors: *P. V. WATKINS[1], S. BANDYOPADHYAY[2], P. O. KANOLD[2]
[1]Dept of Biol., [2]Univ. of Maryland, College Park, MD

Abstract: The functional responses of cortical neurons are sculpted by cortical microcircuits. Auditory cortex neurons show a tonotopic gradient of frequency selectivity based on an orderly projections from the thalamus. Intracortical excitatory and inhibitory connections from neurons in specific locations relative to each cell and to the tonotopic gradient can form modules to combine features to create complex receptive fields. However, the intralaminar micro-circuit organization of the supragranular layer of auditory cortex is unknown. Previous studies involving anatomy or simultaneous patch recordings demonstrated that intralaminar connection probability decreases with distance. Recent application of quantitative optical techniques to neurophysiology has allowed for micro-circuitries of cortex to be measured much more precisely. Here, we

characterize the inhibitory and excitatory micro-circuits in supragranular layers of mouse auditory cortex in 2D by a combination of laser scanning photostimulation, whole cell patch recordings and 2-photon Ca2+-imaging. We find that both inhibitory and excitatory connections within auditory cortex show a spatial anisotropy with regards to the tonotopic axis on different spatial scales. Such anisotropy was absent in the visual cortex. These results suggest a stereotypical integration of stimulus feature information across the supragranular layers of auditory cortex.

Title: Perception of phasing, and motor response to subliminal phase shifts

Authors: *J. WHITALL[1], P. VISWANATHAN[1], J. L. CONTRERAS-VIDAL[2], F. A. KAGERER[3]
[1]Univ. of Maryland, Baltimore, Baltimore, MD; [2]Electrical & Computer Engin., Univ. of Houston, Houston, TX; [3]Kinesiology, Neurosci. Program, Michigan State Univ., Lancing, MI

Abstract: Unilateral tapping studies have shown that adults adjust to both perceptible and subliminal changes in phasing or frequency. This study focuses on the phasing responses to abrupt/perceptible and gradual/subliminal changes in auditory-motor relations during bilateral tapping in response to stimuli presented alternating between the two ears.
We investigated these responses in 18 healthy adults (mean age: 24.5 yrs) with and without a high perceptual acuity relating to phase shifts of acoustical stimuli as determined by an auditory threshold determination (threshold<20°: 'high' acuity). After two baseline trials of 180° phase difference (=beats regularly alternating between the two earphone speakers), the phase relationship was changed over the next eight trials either abruptly (20° or 45° shift), or gradually, increasing in 5° steps, with two repetitions per step, amounting to a total phase shift of 20°. Adults in both groups alternately tapped their index fingers in synchrony with auditory cues set at a frequency of 1.4 Hz. Both groups modulated their responses to perceptible and to subliminal changes as low as 1.4% (a 5º change) in phasing. The high threshold participants were more variable than those with low threshold in their responses in the gradual condition. Both groups

showed a synchronization asymmetry between dominant and non-dominant hands associated with the abrupt condition, as well as the later blocks of gradual condition.
Our findings suggest the presence of a subliminal phasing response mechanism to auditory cues that appears to be relatively independent of the ability to consciously perceive the auditory cues.

Title: Stimulus temporal coherence strongly influences rapid plasticity in primary auditory cortex

Authors: Y. XU, P. YIN, *S. A. SHAMMA
Univ. of Maryland, College Park, MD

Abstract: Temporal coherence of stimulus features is a key property of sounds that emanate from single source. Consequently, it is important to understand how it may influence the direction and extent of the rapid plasticity postulated to occur during the streaming of concurrent sounds. We postulated that when animals listen attentively to coherent and or incoherent stimuli, responses would adapt to effectively encode the correlational structure of the stimuli. Specifically, that correlated responses would promote mutually excitatory interactions among the neurons, and hence would rapidly enhance the responses. The opposite would occur between uncorrelated neurons, causing rapid response depression. Ferrets were trained to attend globally to two-tone sequences that were played randomly either to be synchronous (SYNC) or alternate (ALT) on a trial-by-trial basis, and to detect a transition to a random cloud of tones by licking a waterspout for reward. Neuronal activities were collected in the primary auditory cortex (A1) during performance of the task compared to passively listening to the same stimuli. In general, neuronal responses to the two-tone sequences (in both SYNC and ALT) adapted rapidly to a steady-state after 3-4 repeats of the tone burst. However, in accord with the hypothesis, a large difference in the steady-state responses was observed for ALT and SYNC responses. Specifically, SYNC (ALT) trial responses were enhanced (suppressed). Analysis of the response time-course indicated that response changes were largely due to a late response component (40-

70 ms time window from the tone onset). These changes were also consistent with receptive field changes measured immediately following the end of tone sequences using the random tone clouds. Specifically, we observed strongly suppressed receptive-fields following ALT sequences, but no changes or slightly enhanced receptive-field following SYNC sequence. These results provide neuronal evidence for the role of stimulus temporal coherence in modulating responses during attentive listening to complex sounds.

Title: Closing the loop on auditory learning in mice: Behavioral characterization and neurophysiologic correlates of learning to hear weak signals in noise

Authors: J. P. WHITTON[1,2], K. E. HANCOCK[2], *D. B. POLLEY[1,2,3]
[1]Harvard-MIT Div. of Health, Sci. and Technol., Boston, MA; [2]Eaton-Peabody Lab., Massachusetts Eye and Ear Infirmary, Boston, MA; [3]Otology and Laryngology, Harvard Med. Sch., Boston, MA

Abstract: Mice are a powerful model system for studies of auditory circuit function and plasticity but, because of their general reluctance to remain still, are difficult subjects to train in conventional auditory behavioral tasks. Given the importance of linking perceptual changes to the development and plasticity of the auditory system, we have tailored a “closed-loop” auditory discrimination task to the mouse, which we believe is better suited to their cognitive and motoric proclivities. In the task, mice were trained to use continuous auditory feedback to locate a randomly placed invisible target in a training arena. In order to provide these cues, the mouse’s position in the behavioral arena was coupled to changes in stimulus features in real time. In this way, the mice were essentially performing a “hot-cold” task, where closer proximity to the target elicited stimulus features similar to the target and greater distance from the target translated to larger deviations from the target stimulus features. In this task, mice were trained to discriminate signal-to-noise ratio by modulating the signal amplitude in a fixed noise background according

to the mouse's Euclidian distance from the target location. The least favorable SNR in the acoustic gradient served as the target auditory cue. Mice learned the procedure within 20 daily training sessions. Over approximately 60 additional training sessions, some mice made modest improvements in their performance accuracy on the task, while reducing the amount of time needed to reach the randomly placed target by 20-30%. Additionally, the animals more efficiently used the auditory gradient to navigate the training arena evidenced by an increase in their ratio of movement trajectories that were directed toward the target. Extracellular recordings from the primary auditory cortex of trained animals suggest that the representation of tonal signals presented in background noise is enhanced relative to passively exposed control mice.

Title: Reaction of neuronal networks in the murine auditory cortex to loud noise exposure

Authors: O. NOVAK, *J. M. SYKA
Inst. Exptl. Med. ASCR, Prague, Czech Republic

Abstract: It is well known that exposure to a very loud sound produces deteriorated hearing function in mammals. However, the details of this auditory deterioration are unknown to a large extent. Using in vivo two-photon calcium imaging, we investigated the reaction of the neuronal networks in the supragranular layers of the murine (C57BL/6J) auditory cortex to noise exposure.
In mice anaesthetized with ketamine/xylazine, we recorded calcium traces (after the injection of OGB1 and sulforhodamine101) as the responses of individual neurons to pure tone amplitude-modulated stimuli. Tonal receptive fields and post-stimulation time histograms (PSTH) of several neurons recorded at the same time were constructed from the responses. In addition, a z-scan of the investigated area up to a depth of 350 μm was obtained. The animals were then exposed to a loud noise (white noise, 120 dB SPL, 30 min). Following the noise exposure, the previously recorded neurons were identified and their responses to tonal stimuli were recorded

again. Finally, the z-scan was repeated as well.
There were no identifiable changes in the morphology of neurons and glial cells throughout the investigated cortical layers when compared before and after exposure to noise. As regards the calcium traces, there were two types of reaction of neurons to noise exposure observed. Some of the neurons preserved their acoustical stimulus-locked firing pattern, but their tonal receptive fields were changed with an increased threshold at the best frequency. The second population of neurons was affected more seriously. The neurons did not maintain their stimulus-locked firing pattern and exhibited increased spontaneous activity.
Our data offer an insight into the changes that occur in the supragranular layers of the auditory cortex in mice after exposure to a loud sound.

Title: Sensory-motor classifications of speech: Selectivity at the interface between speech perception and production

Authors: *G. B. COGAN[1], T. THESEN[2], C. CARLSON[3], W. K. DOYLE[4], O. DEVINSKY[3], B. PESARAN[1]
[1]Ctr. for Neural Sci., CNS - NYU, New York, NY; [2]Dept. of Neurol., [3]Comprehensive Epilepsy Ctr., [4]Dept. of Neurosurg., NYU Langone Med. Ctr., New York, NY

Abstract: Neural recordings obtained directly from the surface of the human brain offer the possibility of high fidelity recordings during the performance of uniquely human faculties such as speech and language, faculties for which animal models offer limited opportunities. Here we build on previous results that sensory motor transformations between speech perceptual auditory representations and production motor representations occur bilaterally and throughout the dorsal stream, and examine the selectivity of sensory-motor representations for spoken words.
Ten patients with pharmacologically resistant epilepsy were sub-durally implanted with an 8 x 8 electrode array (1 cm spacing; Adtech) in the temporal-frontal region. Patients were presented with one of 7 auditory CVC (consonant-vowel-consonant) syllables that differed solely on the vowel (hat, het, heat, hoot, hut, hot, hit). Subjects had to either overtly repeat these syllables after

a short delay of 2 seconds (listen-speak), or repeat after a delay without any overt sound (listen-mime). For the present analysis, these two conditions were collapsed together. A control passive listening condition was also present but not analyzed in the current study. We performed a binary classification using a multivariate linear classifier on each combination of tokens presented on electrodes that display sensory motor activity (active during both the presentation of the token as well as the repetition) using the high gamma response (70-160 Hz) on each trial. Out of 36 measured sensory motor sites, 31 displayed a significant number of binary classifications (31/36, 86.11 %). For sites that displayed significant selectivity, classification scores ranged from 0.61 to 0.90 (mean+/1sd = 0.68 +/- 0.06) (chance = 0.50). The average number of significant classifications per significant electrode was 7.16 (out of a maximum of possibility of 21). Furthermore, classifications at the sensory-motor sites during either the auditory epoch or the production epoch alone displayed different selectivity patterns: 72 % of significant binary contrasts were selective in the auditory epoch or the production epoch but not both. This suggests different forms of representation during each task epoch. Taken together, these results suggest that the sensory-motor system that links speech perception and production is selective for individual word tokens and that this selectivity gives further evidence for a transformation from sensory to motor based representation at the interface of the speech perceptual and production systems.

Title: Information flow in the ascending auditory system

Authors: *M. J. SCHACHTER[1], F. E. THEUNISSEN[2]
[1]UC Berkeley, San Francisco, CA; [2]Psychology, UC Berkeley, Berkeley, CA

Abstract: The neural representation of complex sounds has been characterized at different levels of the avian auditory system, and one of the conclusions of this body of work is that neurons in higher auditory areas, such as NCM (Nidopallum caudal medial) and CM (caudal Mesopallium) can have selective responses for conspecific songs or, more generally, familiar stimuli. However,

the role of the ascending circuitry in generating these complex responses is not well understood. To better study how the information flow in the ascending auditory system and, in particular, the role of both the local and global circuit architecture, we examined the population response of 192 cells recorded in the auditory midbrain, thalamus and pallium to a set of 18 different songs. As in previous work, we characterized the spectro-temporal receptive field (STRF) and the information both of single neurons and of neuronal assemblies to study changes in response properties. We further characterized non-linear response properties by fitting STRFs with different input and output non-linearities. Nonparametric output nonlinearities enhanced model performance primarily through a threshold-like mechanism.
In parallel, we modeled a cell response from the linear combination of the responses of other neurons to obtain what we call a neural receptive field (NRF). We used these NRFs to find neural assemblies with similar response properties as well as putative functional connectivity patterns within and across regions. Functional connectivity appears recurrent and on average hierarchical. CM cells prefer input from Field L (primary auditory cortex) and other CM cells. Field L cells prefer input from CM, Field L, and OV (auditory thalamus). Interestingly, both Field L and CM responses share some precise spike-timing properties of MLd cells, indicating a preservation of midbrain response properties up the hierarchy to cortex. The preservation of responses with high temporal precision appears to be a distinctive feature of auditory systems; we postulate that it is so because temporal information remains critical for high-level tasks such as separating song from noise in auditory scene analysis.

Title: Encoding of complex sound in inferior colliculus

Authors: *D. LYZWA[1], M. J. HERRMANN[2], *F. WÖRGÖTTER[3]
[1]Dep. Nonlinear Dynamics, Max Planck Inst. for Dynamics and Self-Organization, Göttingen, Germany; [2]Inst. of Perception, Action and Behavior, Univ. of Edinburgh, Edinburgh, United Kingdom; [3]Third Inst. of Physics–Biophysics, Georg-August-University, Göttingen, Germany

Abstract: Spectro-temporal response properties along different spatial axis within the inferior colliculus to complex sound are studied. Vocalizations, being natural stimuli and showing a variety of spectral and temporal modulations are particularly interesting and can capture evoked responses which are neglected by artificial simplified sounds.
We study responses from guinea pigs to acoustically presented species-specific vocalizations. The multi-unit recordings were taken simultaneously from 32 positions in the central nucleus of the inferior colliculus of Dunkin Hartley guinea pigs using a double shank electrode.
The vocalizations differ in spectral content and envelope shape, ranging from low to broad spectral distributions and from a highly periodic to complex envelope, and can be ordered accordingly.
Response preferences to features of the complex sounds depend largely on the characteristic frequency of the neural population, showing e.g. enhanced response for low frequency content and periodic envelopes at low CF.
Post-stimulus time histograms of the neural populations can be partly predicted by taking into account cochlear frequency band filtering, and their measured tuning curves in the ICC.
Neural discrimination between different vocalizations using linear discriminant analysis yields time windows of 0.5 ms as sufficient to distinguish features of these complex sounds.
Pooling responses from recording sites with fairly different response properties leads to improved discrimination, and is not decreased when lifting temporal correlations by shuffling across trials, which indicates independent encoding schemes. Only directly neighboring (100 μm) neural populations respond in a similar manner and have highly correlated PSTHs.
This suggests that for electrical stimulation in the IC several contacts are necessary in order to best approximate the evoked response to complex sounds.

Title: A temporal integration mechanism for enhancing frequency tuning between brainstem inputs and the inferior colliculus

Authors: *C. CHEN, H. L. READ, M. A. ESCABI
Univ. Connnecticut, Storrs, CT

Abstract: Sound information is processed through parallel pathways that synapse within the inferior colliculus (IC) and yet there is little direct evidence for how these inputs serve to create or preserve neural representations of sound. Using tetrode arrays we provide evidence for the presence of pre-synaptic action potentials ("prepotentials") within the cat IC and demonstrate a dramatic enhancement in spectral selectivity between putative input (PIN) and target IC neurons (ICN). Two pathways of PINs are identified that reflect the presence of functionally distinct parallel pathways to the IC. PINs were matched in best frequency to ICN yet exhibited broadly tuned and temporally delayed patterns of excitation and inhibition. A subset of PINs had temporally precise and spectrally interleaved peaks that that resemble a comb-filter. A neuron model that takes into account the synaptic activity of PINS and the subsequent membrane integration in the IC accounts for the radical sharpening of tuning observed in ICN responses. Sharpening of tuning is accomplished by temporal integration of the converging PIN activity where spectral excitation and inhibition are out of phase and summate at the BF but are overlapped and cancel away from BF. Thus spectral selectivity can be newly generated through constructive and destructive interferences by a temporal integration mechanism not requiring local surround inhibition. (Supported by NIDCD R01DC006397).

Title: Inactivation of ventral prefrontal cortex impairs audiovisual working memory.

Authors: *B. PLAKKE[1], J. HWANG[2], M. D. DILTZ[1], L. M. ROMANSKI[1]
[1]Dept. of Neurobio. & Anat., Univ. of Rochester Sch. of Med., Rochester, NY; [2]Johns Hopkins, Baltimore, MD

Abstract: The ventral frontal lobe is well known for its role in language processing and social communication. Previous work from this lab has demonstrated that individual neurons within ventrolateral prefrontal cortex (VLPFC) process and integrate face and vocal information (Romanski et al., 2005; Sugihara et al., 2006). We have also recently shown that VLPFC neurons are active during audiovisual working memory (Hwang and Romanski, 2010). The effect of VLPFC lesions on tasks which assess learning or memory has been equivocal, with some studies demonstrating an impairment on visual learning and memory, auditory discrimination, rule learning, and decision making, while other studies have failed to demonstrate any deficits during working memory tasks. In the current study we asked whether VLPFC was essential in an audiovisual non-match-to-sample (NMTS) task designed to assess auditory and visual working memory. During the task, monkeys attended the audiovisual sample and were required to press a button when a non-matching stimulus, i.e. one whose auditory or visual track differed from the sample audiovisual movie, occurred. Our subjects, rhesus macaques, detected the non-match with a button press in order to receive a juice reward. We inactivated VLPFC while subjects performed the task by cooling the cortical surface of VLPFC below 20° C. During each testing session, 100 baseline trials were completed (WARM trials) and then the cortex was cooled below 20° C, and another 100 trials were completed (COLD trials). We assessed performance accuracy and reaction time in the auditory and visual non-match trials of the audiovisual NMTS task during WARM and COLD trials. Performance accuracy was significantly decreased during COLD trials compared to performance during WARM trials. Interestingly, performance accuracy was significantly worse on auditory mismatch trials compared to visual mismatch trials during the COLD trials. Reaction time was not significantly different between warm and cold trials. This data confirms that VLPFC plays a role in audiovisual processing and that VLPFC may be essential in auditory working memory.

Title: Macaque sensitivity to compound amplitude modulation: Effects of component frequency and phase

Authors: *K. N. O'CONNOR, Z. CLINE-EGRI, J. S. JOHNSON, M. L. SUTTER
Ctr. for Neurosci., UC Davis, Davis, CA

Abstract: Most of the variation in the temporal envelope of natural sounds occurs at relatively low frequencies (Voss and Clark 1975; Singh and Theunissen 2003). Slow amplitude modulations (AM) are particularly prominent in human and animal vocalizations, and it is evident that this envelope variation carries important communicative information. For example, comprehension of human speech is possible with as few as three modulated noise bands (Shannon et.al. 1995). How the brain extracts this information is currently of much interest in both psychophysical and physiological acoustics. Several adaptation and masking studies support the notion that temporal envelope analysis is effectively based on a "modulation filterbank", a bank of independent bandpass filters each sensitive to a narrow range of AM frequencies (e.g., Kay and Matthews 1972; Bacon and Grantham 1989; Ewart and Dau 2000). To test this model, and examine its possible physiological bases, we have begun training rhesus macaques to detect envelope modulation in compound AM (cAM) stimuli, consisting of broadband noise carriers where the modulation function is the sum of two sinusoids. The frequencies of these sinusoids are either quite close (e.g., 5 and 6.25 Hz), designed to lie within a modulation filter, or farther apart and so not within the same filter (5 and 15 Hz). Additionally, the phases of the two sinusoids are either aligned at 0 deg or 180 deg apart. This phase manipulation produces two signals with identical modulation spectra, but different waveforms and envelopes. If cAM sensitivity is based upon a modulation filterbank we would expect summation effects for detection of the signal components lying within a filter, but little or no summation for those not within. We would also expect phase difference to have no effect on summation. To date, we have obtained preliminary results from one macaque. Comparison of thresholds for detection of the pure sine component AM, to those for detection of compound AM, suggests that summation is greater in the case of 5 + 6.25 Hz cAM, but that it also occurs to some degree for the 5 + 15 Hz cAM. It appears that phase also has an effect, with greater summation for cAM with non-aligned phase. Thus, our results at this point are not strongly supportive of a modulation filterbank model in the macaque comprising narrow independent filters, though they may be more congruent with a model in which the filters share a common noise source.

Title: Activity-dependent intrinsic plasticity of principal cells of the medial superior olive near the onset of hearing

Authors: T. BABOLA, S. CHERRY, *N. L. GOLDING
Univ. of Texas At Austin, AUSTIN, TX

Abstract: Within days after hearing onset, principal neurons of the medial superior olive (MSO) transform from slow, electrically compact neurons into fast, leaky neurons capable of detecting sub-millisecond differences in the timing of binaural excitatory and inhibitory inputs, cues used for encoding the location of sounds along the horizontal plane. While the electrical maturation of intrinsic properties has been characterized previously, little is known about how this transformation occurs developmentally or what mechanisms are involved. To address these questions, we delivered repetitive synchronous activation of excitatory inputs to MSO neurons in brainstem slices from gerbils just prior to hearing onset (P9-P11). Subthreshold synaptic stimulation (trains of 10 monolateral stimuli at 100 Hz, repeated 20 times once every 5 s) produced an average decrease in input resistance (R_N) of 44±11% (n=8), the equivalent of ~2 days of development after hearing onset. The resting potential (V_m) also hyperpolarized by ~17 mV (from -54±1 mV to -71±3 mV, n=8). These changes typically occurred 5-10 minutes after stimulation and persisted for the duration of recordings (>30 min. post-stimulus). When subthreshold synaptic stimuli (4-10 mV amplitude) were paired with action potentials triggered at the peak of each EPSP by depolarizing current pulses, a similar decrease in R_N was observed (54±9%) along with a 10±4 mV hyperpolarization of the resting membrane potential (n=5). However, action potential trains alone did not elicit these changes. Activity-dependent changes in R_N were attenuated by blocking NMDA receptor-mediated calcium influx with 50 µM AP-5 (17±11% decrease in R_N, 8±2 mV hyperpolarization of V_m, n=4) and completely blocked by depleting intracellular calcium stores with 100 µM cyclopiazonic acid (2±7% decrease in R_N, 0±2 mV change in V_m, n=7). In addition, LY379268 (100 nM), a group II metabotropic glutamate receptor (mGluR) agonist, decreased R_N by 40±5% and hyperpolarized the membrane potential by 9±2 mV (n=8). The similarity between the effects of the group II mGluR agonist to those induced by synaptic stimulation suggest that these receptors may play an important role in the maturation of intrinsic electrical properties. Based on our results, we propose a model for the development of temporal precision in MSO principal cells in which the increase in temporal correlations across excitatory inputs during early auditory experience activate mGluRs and NMDARs, which then cooperatively trigger calcium-induced calcium release and subsequent changes in intrinsic ion channels, improving the speed and precision of binaural cue processing.

Title: Depletion of vesicular GABA in horizontal cells eliminates inhibitory feedback to photoreceptors in mammalian retina

Authors: *A. A. HIRANO[1,2], X. LIU[3], L. PÉREZ DE SEVILLA MÜLLER[3], J. BOULTER[4], S. BARNES[6,3,2], N. C. BRECHA[5,2]

Abstract: While it is accepted that horizontal cells provide inhibitory feedback to photoreceptors, the cellular mechanisms and transmitter(s) underlying this inhibition in mammalian retina are less well understood. The localization of vesicular GABA transporter (VGAT) and other SNARE and synaptic proteins to horizontal cell processes and endings indicate the vesicular release of GABA may in part participate in horizontal cell function. The goal of this study was to determine whether vesicular GABA in horizontal cells participates in inhibitory feedback to photoreceptors. We generated a Cx57-iCre mouse line and crossed it with a transgenic line containing LoxP-flanked VGAT genes to eliminate VGAT selectively in horizontal cells (Cx57-VGAT null). Immunohistochemistry for VGAT on retinal sections confirmed that VGAT was eliminated from horizontal cell processes and endings in the outer retina. Analysis of iCre expression in whole-mounts of Cx57-iCre retinas indicated that iCre was expressed in all horizontal cells, identified by calbindin immunolabeling, in all regions of the retina. Moreover, Cx57- iCre crossed with a cre reporter line, to generate the Cx57-tdTomato (Cx57-Tom) line, showed fluorescent protein expression in horizontal cells distributed to all regions of the retina. Homologous coupling of horizontal cells in heterozygous Cx57-iCre-

VGAT null mice is intact. To assess inhibitory feedback to photoreceptors, retinal slices from Cx57-VGAT null and control mice loaded with Fluo-4 were imaged on a Zeiss Pascal confocal microscope. Brief superfusion with 30 mM K^+ activated photoreceptor L-type Ca channels. 50 µM Kainate (KA) and 50 µM NBQX were used to alter the feedback signal from horizontal cells. In slices from control mice, KA inhibited high-K^+-evoked Ca^{2+} signals in photoreceptors by 22% and NBQX enhanced signals by 23%, consistent with previous reports. In contrast, in retinal slices from Cx57-VGAT null mice, KA failed to inhibit high-K^+-evoked Ca^{2+} signals and NBQX failed to enhance these signals in photoreceptors, suggesting that inhibitory feedback from horizontal cells was inactive in Cx57-VGAT null mice. Taken together, the results indicate that vesicular GABA from horizontal cells is critical for feedback inhibition onto photoreceptors.

Title: Feedback inhibition extends the dynamic range of luminance and contrast coding

Authors: *N. W. OESCH, J. S. DIAMOND
NINDS/NIH, BETHESDA, MD

Abstract: The nervous system often encodes changes in signal level, rather than absolute level allowing for efficient coding of inputs over a large range. In the visual system, where this challenge is particularly acute, the measure of difference between luminance values is referred to as contrast. Recently, we demonstrated that the rod bipolar cell (RBC) synapse in the retina both computes contrast and relays luminance information in its synaptic output, and we demonstrated that contrast is calculated by a mechanism intrinsic to the synapse. This mechanism, in isolation, accurately computes contrast over only a restricted range of background luminance values, yet our perception of contrast remains constant across the entire range of vision. This argues that additional mechanisms must shape the computation of contrast. The rod bipolar cell synapse receives local reciprocal feedback inhibition, yet the role of local feedback inhibition in visual function is currently unknown. To examine the role of feedback inhibition in the computation of contrast we made whole-cell current and voltage-clamp recordings from the post-synaptic

partner of the RBC, the AII amacrine cell, and recorded post-synaptic potentials and excitatory post-synaptic currents in response to visual stimulation, while pharmacologically manipulating feedback inhibition. Here we demonstrate that feedback inhibition extends the range over which both contrast and luminance can be coded by the RBC synapse.

Title: A forward transgenic approach to zebrafish retinal circuitry

Authors: P. M. COHEN[1], F. ONO[2], S. E. BROCKERHOFF[3], *R. F. NELSON[1]
[1]Neural Circuits Unit, NINDS, NIH, Bethesda, MD; [2]Section on Model Synaptic Systems, NIAAA, NIH, Bethesda, MD; [3]Dept. of Biochem., Univ. of Washington, Seattle, WA

Abstract: Zebrafish (Danio rerio) are a genetic model for vertebrate color vision with retinas that are rich in color processing neural circuitry. A large facet of this circuitry is the lateral inhibitory network of horizontal cells that regulate cones, and which have different spectral responses to light of different wavelengths and irradiances. In this study, we used a forward transgenic ‘enhancer trap’ approach to produce a transgenic line that selectively labeled a subset of horizontal cells with eGFP. We then crossed this line with a TαCP-tdTomato line that labeled all cones with tandem dimer (td) Tomato in order to determine how these horizontal cells connect to cones of different spectral types. These connections were examined in flatmount and 25 µm frozen sections. Horizontal cells were imaged by confocal microscopy and z-stacks were taken at intervals of 1.1 µm (×40 water immersion objective) and 0.71 µm (×63 water immersion objective). The results demonstrate that the forward transgenic-labeled horizontal cells contact at least one ultraviolet cone and one double cone, indicating that they are H2 cells. The double cone contacts were confirmed in zpr-1 labeled retinas. Other studies have shown that this pattern of connections arises in spectrally biphasic types. We found that the transposon gene insertion was located in a non-coding DNA region on chromosome 14. We suspect that this insertion is within a regulatory sequence, and may report on the expression of a distant conserved gene. Our results

show that the enhancer trap method, a forward genetic approach, can selectively label chromatic horizontal cells, enabling visualization of their specific contacts with cones.

Abstract: Otx2 homeoprotein transcription factor is expressed in a variety of neural tissues including the retina where its messenger RNA can be detected in photoreceptors and bipolar cells. We analyzed the retina of mice with constitutive haplodeficiency in which one Otx2 allele was replaced by GFP (Otx2 +/GFP mouse). The expression of marker genes for different cell types was analyzed by RT qPCR in retina from 3 month-old Otx2+/GFP mice and compared with that of their wild-type littermates. No difference was observed in the expression of markers for retinal ganglion cells (RGCs), horizontal cells, amacrine cells or photoreceptors whereas the expression of PKCα mRNA - a marker of some bipolar cells - was reduced in the retina of the mutant mice. Histological analyses confirmed no cell loss in the ganglion cell layer and showed no change in the thickness of the outer nuclear layer suggesting no reduction in the number of RGCs, displaced amacrine cells or photoreceptors. However, the inner nuclear layer (INL) was significantly thinner in mutant mice and the number of cells in this layer was reduced by about 23%. Chx10/Vxx2 immunofluorescence showed that a reduced number of bipolar cells explained

the cell loss in the INL. The number of PKCα-positive cells was reduced in the INL corroborating the RT qPCR results indicating a loss of rod ON bipolar. Interestingly, no recoverin-labeled cell bodies could be observed in the INL of 3 month-old Otx2 +/GFP mouse retina reflecting a total absence of type 2 OFF bipolar cells. In conclusion, our results show that RGCs and photoreceptors are not sensitive to Otx2 haplodeficiency, whereas INL integrity, notably its bipolar cell content, depends on full Otx2 gene expression.

Title: Computational model for the formation of asymmetric connections from starburst amacrine cells to ganglion cells underlying direction selectivity in the developing retina

Authors: *S. TANAKA[1], K. YANAGAWA[1], M. MIYASHITA[2], M. YAMADA[3], S. USUI[3]
[1]The Univ. of Electro-Communications, Choufu-Shi, Tokyo, Japan; [2]Numazu Natl. Col. of Technol., Ohoka, Numazu, Shizuoka, Japan; [3]RIKEN Brain Sci. Inst., Wako, Hirosawa, Saitama, Japan

Abstract: To date, numerous studies have been attempted to elucidate how direction selectivity is formed in some types of retinal ganglion cells (GCs) during early development. Recent reports from Feller's group have clarified that the conductance of $GABA_A$Rs at postsynaptic sites from starburst amacrine cells (SACs) to a direction selective ganglion cell (DSGC) in a null side markedly increased between postnatal 7 and 14 days (P7-P14). Since blockade of neural activity during this period did not affect the formation of direction selectivity, the mechanism underlying the formation DSGCs is suspected to be activity independent. Nevertheless, it seems hard to consider that some innately expressed molecules govern the connectivity from a large number of SACs to each GC. In this study, we propose a two-step mechanism for DSGC formation, where two steps I and II are divided by the timing of GABA switch around P8. (I) Cholinergic connections from SACs to GCs are transiently formed depending on neural activity before P8. (II) $GABA_A$Rs are gradually aggregated in an activity-independent manner by taking over postsynaptic positions of nAChRs. That is, the early formed cholinergic connections scaffold the

asymmetric GABAergic connections from SACs to GCs. If this scenario holds, we need to focus on step (I) and examine whether asymmetric cholinergic connections can be formed from SACs to GCs. To build a model, we took into account Ca^{2+}-permeable nAChRs composed of α7 subunits, $GABA_A$Rs depolarizing membrane potential of GCs, Ca^{2+} influx from extracellular space through voltage gated calcium channels, Ca^{2+}-induced Ca^{2+} release from intracellular calcium stores, lateral diffusion of nAChRs and $GABA_A$Rs on the membrane of dendrites, and Ca^{2+}-dependent interaction between nAChRs and postsynaptic membrane-binding proteins. We derived a nonlinear synapse formation model based on the above observations. Computer simulations showed that asymmetric connections from SACs to a GC are formed if and only if synaptic outputs from SACs are limited to the 1/3 of distal dendrites of SACs, as consistent with the functional morphology of SACs.

Title: Cannabinoid receptor 1 agonists differentially modulate light-evoked OFF responses in mouse retinal ganglion cells under light adaptation

Authors: *J. N. PAHNG, J. YANG, G.-Y. WANG
Dept. of Structural and Cell. Biol., Tulane Univ., New Orleans, LA

Abstract: Endocannabinoids (eCBs) are retrograde neurotransmitters that are released from postsynaptic cells, bind to presynaptic cannabinoid receptor 1 (CB1R), and prevent release of transmitter from the presynapse. Studies in brain have shown that CB1R activation may inhibit postsynaptic neurons by preventing glutamate release from the presynapse, or it may excite postsynaptic neurons by preventing GABA release from the presynapse. In retina, CB1Rs have been localized to both glutamatergic and GABAergic presynaptic sites suggesting that retinal eCBs have a role in modulating both excitatory and inhibitory neurotransmission. Indeed, synthetic cannabinoid WIN 55,212-2 (WIN) application has been shown to decrease spontaneous glutamate and GABA currents recorded in mouse retinal ganglion cells (RGCs). However, it is currently unknown how eCBs modulate light-evoked responses in RGCs. To understand the role

of eCBs in visual signal processing in the retina, we performed whole-cell voltage clamp recordings of light-evoked OFF responses in mouse RGCs before and after bath application WIN under light adaptation. We found that WIN decreased the amplitude of light-evoked OFF responses in one population of retinal ganglion cells, but increased the amplitude of light-evoked OFF responses in another population of retinal ganglion cells. $GABA_C$- specific antagonist TPMPA prevented the WIN-induced increase in the amplitude of light-evoked OFF responses. Similar results were observed in experiments where WIN was replaced with the eCB 2-arachidonoylglycerol (2-AG). The results, in conjunction with previous CB1R localization studies, indicate that WIN decreases light-evoked OFF amplitudes in one population of RGCs by primarily reducing glutamate release, but WIN increases light-evoked OFF responses in another population of RGCs by reducing GABA release onto bipolar cell axon terminals.

Title: Distinctive patterns of alterations in proton efflux from goldfish retinal horizontal cells monitored with self-referencing H+-selective electrodes.

Abstract: The H+-hypothesis of lateral feedback inhibition in the outer retina predicts that depolarizing agents should increase H+ release from horizontal cells. To test this hypothesis, self-referencing H+-selective microelectrodes were used to measure extracellular H+ fluxes from isolated goldfish horizontal cells. We found a more complex pattern of cellular responses than previously observed from horizontal cells of other species examined using this technique. One class of cells had an initial standing signal indicative of high extracellular H+ adjacent to the cell

membrane; challenge with glutamate, kainate or high extracellular potassium induced an extracellular alkalinization. This alkalinization was reduced by the calcium channel blockers nifedipine and cobalt. A second class of cells displayed spontaneous oscillations in extracellular H+ that were abolished by cobalt, nifedipine and low extracellular calcium. A strong correlation between changes in intracellular calcium and extracellular proton flux was detected in experiments simultaneously monitoring intracellular calcium and extracellular H+. A third set of cells was characterized by a standing extracellular alkalinization which was turned into an acidic signal by cobalt. In this last set of cells, addition of glutamate or high extracellular potassium did not significantly alter the proton signal. Taken together, the response characteristics of all three sets of neurons are most parsimoniously explained by activation of a PMCA pump, with an extracellular alkalinization resulting from exchange of intracellular calcium for extracellular H+. These findings argue strongly against the H+ hypothesis of lateral inhibition.

Title: The influence of dopamine on the spiking activity of dopaminergic amacrine cells

Authors: *M. L. RISNER, D. G. MCMAHON
Biol. Sci., Vanderbilt Univ., Nashville, TN

Abstract: Dopamine is a major neurotransmitter that regulates learning and memory, mood, motor movement, sleep and waking, and vision. Dopaminergic neurons contributing to these processes are present in several areas of the central nervous system, including the substania nigra, ventral tegmental area, and retina. Dysfunction of dopaminergic neurons in these areas is related to Parkinson's disease, mood disorders, schizophrenia, addiction, and low vision.
We have recently generated a mouse line with a conditional allele of tyrosine hydroxylase (*TH*KO), the rate-limiting enzyme in dopamine production, and this conditional tyrosine hydroxylase allele is subject to deletion by a Cre/lox recombination system. To investigate the spiking properties of dopaminergic amacrine (DA) cells in *TH*KO animals, loose-patching recordings were made from whole-mount retinas. In addition, we examined if the D2 dopamine

receptor, native to wild-type DA cells, is present in *TH*KO retinas by applying exogenous dopamine to the bath solution.
Preliminary data suggests that the baseline spike dynamics of DA cells in *TH*KO retinas are similar to those observed in wild-type animals. We have also found that DA cells in THKO retinas are sensitive to exogenous dopamine. We will further investigate the role of dopamine in light adaptation in this mouse model at the retinal ganglion cell level.

Title: Ganglion cell morphology is altered in late stages of Retinitis Pigmentosa

Authors: *E. E. O'BRIEN[1,2,3], U. GREFERATH[2,3], E. L. FLETCHER[2,3]
[1]Dept. of Electrical & Electronic Engin., [2]Dept. of Anat. and Neurosci., Univ. of Melbourne, Melbourne, Australia; [3]Bionic Vision Australia, Melbourne, Australia

Abstract: Retinitis Pigmentosa (RP) refers to a family of inherited photoreceptor degenerations resulting in blindness. Our research focuses on further understanding the disease process of RP particularly during mid to late stages when total loss of photoreceptors has occurred and significant remodelling of inner retinal neurons has taken place. Triple mutant transgenic mice, rd1-FTL-Thy1, contain a mutation in the β subunit of phosphodiesterase 6 leading to RP, an axon-targeted β-galactosidase (β-gal) reporter system which is under the regulation of the c-fos gene as well as a fluorescent protein that labels a subset of ganglion cells in the retina. Retinae from mice between P90 to P365 were prepared as wholemounts and processed using immunohistochemistry. In rd1-FTL-Thy1 mice we have previously observed an increase in β-gal expression during photoreceptor degeneration (P10-26) followed by a complete loss of expression (P90). At P120 strong upregulation of β-gal reoccurred in the central retina, despite the loss of all photoreceptors and this expression remained until P365. Interestingly, co-localisation with glial cell markers revealed a glial dysfunction in this area. To investigate whether this β-gal expression was also associated with any morphological change in ganglion cells, we classified ganglion cells in the wild-type and rd1-FTL-Thy1 retina (cells=1065, n=28) based on their soma area, dendritic field size and stratification of dendrites into the inner plexiform layer. The dendritic fields of some ganglion cells (cells=605, n=28) were also further

analysed for their total length, total area and quantity of branching points. Interestingly, there was a decrease in size and complexity of the largest ganglion cell type, A, in the degenerated retina from as early as P90. In contrast, the smaller cell types, B and C, remained unchanged throughout degeneration. However, at P330 reductions in the coverage and complexity of these smaller cells types was observed only in regions that also expressed β-gal. This indicates that the integrity of neighbouring neurons and glia may impact surviving ganglion cells at later stages of degeneration. At P330 bi-stratified ganglion cells also showed a reduction in their coverage across the retina. Overall, there were significant changes in many types of ganglion cells at late stages of degeneration. We propose that these changes in ganglion cell morphology will most likely impact the function of individual cells as well as the retinal circuitry in the degenerated retina.

Title: A novel transgenic approach to study the function of horizontal cells on color and contrast vision

Authors: *L. C. HOLZHAUSEN, R. H. KRAMER
MCB, Univ. of California, Berkeley, CA

Abstract: Color vision allows us to appreciate the world in all its detail and beauty. The neural processing that generates color vision begins at the first synapse of the retina, where cone photoreceptors provide input to bipolar and horizontal cells (HCs). HCs project laterally in the retina, integrate inputs from many photoreceptors, and send feedback signals to cones establishing the center-surround receptive field, which is important for contrast vision. HCs also mediate feedback between cones with different spectral sensitivities and contribute to color opponency, providing the basis for color vision. Here, we use a transgenic approach in zebrafish to study the role of HCs in color and contrast vision.
In order to selectively depolarize or hyperpolarize HCs pharmacologically, we use two transgenic zebrafish lines that express exogenous neurotransmitter receptors in HCs. To enable HC-depolarization, we express a FMRF-amide sodium channel (FaNaC) from Helix aspersa.

FaNaC is a sodium selective channel that is activated by the peptide FMRF-amide. To hyperpolarize HCs, we express the newly developed chimeric channel PSAM-GlyR (Magnus et al. (2011), Science). PSAM-GlyR possesses a pharmacologically selective actuator molecule (PSAM), which binds to a chemically unique agonist. Its ion pore domain is from a glycine receptor. Together, both transgenic lines allow us to specifically activate or inhibit HCs pharmacologically, independent from any light-mediated cone signals.
We have successfully generated transgenic zebrafish lines that exhibit germline transmission of the FaNaC and PSAM-GlyR genes. Using electroretinogram (ERG) recordings on zf-larvae, we have found that expression of FaNaC in HCs does not affect retinal light responses in the absence of FMRF-amide. After the FMRF-amide addition we have detected a change in the b-wave amplitude in ERGs. The ERG b-wave amplitude represents synaptic transmission from cones to on-bipolar cells. Our results suggest that depolarization of HCs via FaNaC causes a change in cone synaptic transmission to bipolar cells, presumably through HC-mediated lateral inhibition of cone synapses. Thus, our transgenic approach provides a unique way to regulate HC activity in vivo and to investigate the role of HCs on the visual response in general as well as contrast and color vision in particular.

Title: Disruption of internal pH gradients alters cytosolic Cl- in retinal amacrine cells

Authors: *V. S. KRISHNAN, E. GLEASON
Louisiana State Univ., Baton Rouge, LA

Abstract: We have previously demonstrated that nitric oxide (NO) can release Cl- from an internal store and that this release is partially dependent upon an NO-dependent acidification of the cytosol (Hoffpauir 2006; McMains and Gleason 2011). We continue to pursue the mechanisms underlying this release of internal Cl- in amacrine cells because the cytosolic Cl- concentration determines the effect of incoming GABAergic and glycinergic synaptic inputs on amacrine cell voltage responses. Our current hypothesis is that endosomal compartments constitute the store because they are known to contain 40-60 mM Cl- and they sustain substantial

proton gradients due to the inward pumping of protons on the V-type proton pumps. Here, we examine the effects of weak bases (methylamine (MA) and chloroquine (CQ)) on the proton distribution in amacrine cells loaded with the acidic compartment label LysoSensor. Additionally, using whole cell voltage clamp recordings of GABA-gated Cl- currents, we explore the effects of methylamine and chloroquine on cytosolic Cl-.
Cultured amacrine cells were loaded with 100nM LysoSensor Green for 20 min, at RT, in the dark. The typical pattern of LysoSensor fluorescence in amacrine cells under control conditions was highly non-uniform with dense patches of fluorescence eccentric to nuclei and in discrete bright spots distributed unevenly throughout neuronal processes. Exposure to either MA (10mM) or CQ (100µM) caused a reversible reduction (mean percent reduction, MA 15%; CQ 23%) of fluorescence intensity in these regions presumably due to the buffering of compartmentalized protons. To test the effects of these reagents on the Cl- store, amacrine cells were voltage clamped in zero Cl- internal and external solutions to isolate the store. Cells were recorded either under control conditions or with internal solution containing either 10 mM MA or 100µM CQ. Cells were held at -70 mV and GABA (20 µM) was applied in 400 msec pulses. Under control conditions, the mean amplitude of the inward GABA-gated current was (3.9±1.7pA) reflecting very low cytosolic Cl- due to dialysis from the 0Cl- solution in the recording electrode. With either MA or CQ in the pipet, GABA-gated currents were significantly larger (MA, 79.7±15.9pA, $p<0.001$; CQ, 26.1±5.0pA, $p<0.0001$) implying that with the reduction in the proton gradient across internal membranes, additional Cl- is being added to the cytosol from an internal compartment. Together, these results suggest that a compartment (such as endosomes) that normally sustains a large proton gradient functions as the Cl- store.

Title: Independent modulation of bipolar cell outputs by reciprocal and lateral inhibition in the inner retina

Authors: *M. TANAKA, M. TACHIBANA
The Univ. of Tokyo, Bunkyo-Ku, Japan

Abstract: Bipolar cells (BCs) send excitatory outputs to amacrine cells (ACs) and ganglion cells, and receive reciprocal and lateral inhibitory inputs from ACs in the inner retina. However, it is not yet known how each inhibitory input modulates BC excitatory outputs and contributes to visual signal processing. Here, we performed whole-cell recordings from the giant axon terminal of Mb1 (ON-type) BCs in goldfish retinal slices and examined the properties of reciprocal and lateral inhibition. Depolarization of an Mb1-BC terminal under voltage-clamp induced reciprocal inhibition in itself and lateral inhibition in neighboring Mb1-BC terminals. Both inhibitory inputs were GABAergic but effects of GABA antagonists were different between two inputs, suggesting that each input may be mediated by a different pathway. After blockade of electrical coupling among dendrites of Mb1-BCs, lateral inhibition was abolished but reciprocal inhibition remained intact. Thus, reciprocal and lateral inhibition may be induced by activation of a single Mb1-BC and multiple Mb1-BCs, respectively. Light stimulation induced reciprocal and lateral inhibition in Mb1-BC terminals. Lateral inhibition became prominent as the area of light stimulation was increased up to approximately 1 mm. Lateral inhibition reduced the light-evoked depolarization of Mb1-BCs at weak light intensity whereas reciprocal inhibition reduced it at high light intensity. Thus, reciprocal and lateral inhibition operates at different light-intensity ranges. We constructed a model of an electrically coupled Mb1-BC array with reciprocal and lateral inhibition based on the experimental results, and we monitored the outputs of the Mb1-BC array to simulated visual inputs and endogenous random noise. We found that the different activation properties of reciprocal and lateral inhibition were effective in noise reduction and improvement of the signal-to-noise ratio of Mb1-BC outputs. Therefore, independent modulation of Mb1-BC outputs by reciprocal and lateral inhibition seems to play important roles in visual signal processing.

Title: Amacrine cells containing vGluT3 in baboon retina

Authors: *D. W. MARSHAK[1,3,3], S. L. MILLS[2], J. M. SUH[1], D. M. DOLINO[1], W. S. LIU[1], R. A. JACOBY[3]
[1]Neurobio. and Anat., [2]Ophthalmology and Visual Sci., Univ. Texas Med. Sch., HOUSTON, TX; [3]Ophthalmology, Baylor Col. of Med., Houston, TX

Abstract: The goal of these experiments was to describe the morphology and synaptic connections of amacrine cells in the baboon retina that contain immunoreactive vesicular glutamate transporter 3 (vGluT3). Retinas were labeled with anti-vGluT3 using an immunoperoxidase method and studied by electron microscopy. There were two types of immunofluorescence experiments, in which the double- or triple-labeled material was analyzed by confocal microscopy. Either vGlut 3 cells and other populations of neurons were labeled using antibodies from two different species, or else retinal ganglion cells were filled with Neurobiotin by intracellular injection, labeled with fluorescent avidin and the retinas labeled with anti-vGluT3. Antibodies from a third species and directed against synaptic markers gephyrin or ribeye were also included in some experiments. The labeled amacrine cells had the morphology characteristic of A8 or knotty type 1 cells described previously, and their dendrites formed two plexuses on either side of the center of the inner plexiform layer. The primary dendrites received synapses from a large GABA-ergic amacrine cell, and the higher order dendrites were both pre- and post-synaptic to other amacrine cells. Based on the light microscopic results, these likely include AII cells, starburst cells, knotty type 2 cells and unidentified glycinergic amacrine cells, but not the polyaxonal amacrine cells coupled to ON parasol cells. The vGluT3 cells received input from ON bipolar cells and made synapses that were not associated with ribbons onto OFF bipolar cells, likely including the DB3 diffuse type. Many synapses from vGluT3 cells onto retinal ganglion cells were observed in both plexuses. In the light microscopic experiments, vGluT3 cells made approximately equal numbers of contacts with midget and parasol ganglion cells, including both ON and OFF types. This was surprising because the vGluT3 cells had been expected to contribute preferentially to the pathway providing input to parasol cells based on their stratification pattern. Puncta containing immunoreactive gephyrin, an inhibitory synapse marker, were found at some of the appositions between vGluT3 cells and each of the four types of labeled ganglion cells; this finding is consistent with a previous report that puncta containing glycine receptors are found in neurons postsynaptic to vGluT3 cells. However, as had also been reported previously, vGluT3 cells did not contain immunoreactive glycine transporter 1. Thus, the vGluT3 cells would be expected to have ON responses to light and make synapses onto neurons in both ON and OFF pathways, but the identity of their neurotransmitter is still uncertain.

Title: GABA-mediated signaling from a retinal interneuron switches back and forth between cones at night and bipolar cells in the day due to dopamine-mediated GABAA receptor trafficking.

Authors: *S. C. MANGEL, A. J. CHAFFIOL, H. CHOI, M. ISHII, Y. CAO, A. ADELAJA, C. RIBELAYGA
Dept Neurosci, Ohio State Univ. Coll Med., COLUMBUS, OH

Abstract: **Purpose**: $GABA_A$ receptor ($GABA_AR$) expression and activity are increased when intracellular cAMP/PKA increases (Vithlani et al., 2011). Because cone-bipolar cell (cBC) dendrites express dopamine D_1, but not D_2Rs, and cone synaptic terminals express D_2, but not D_1Rs, cAMP/PKA activity is high in cBC dendrites in the day following prolonged (>30 min) light adaptation when their D_1Rs are activated, but high in cone terminals at night in the dark when their D_2Rs are not activated by the retinal circadian clock. We therefore determined whether 1) cones and cBCs express $GABA_A$Rs in the day and night and 2) the effects of GABA release from horizontal cells (HCs), an interneuron presynpatic to cones and cBCs, vary with day and night.
Methods. Rabbits and goldfish were light (photopic)-adapted for 1 h in the day or dark (low scotopic)-adapted for 1 h in the day or night. Retinal sections were processed in an identical manner for immunostaining with anti-$GABA_AR$ (β2/3) antibodies (rabbits: bd-17; fish: 62-3G1). Double labeling with cell type-specific antibodies determined whether $GABA_A$Rs are located on cone terminals (zpr-1) and ON-cBC dendrites (Goalpha). The effects of gabazine ($GABA_AR$ antagonist) on rabbit cBCs and goldfish cones were studied in the day and night using whole-cell patch-clamp recording.
Results. $GABA_AR$ antibody labeling 1) was observed on ON-cBC dendrites, but not cone terminals, following prolonged light adaptation in the day under control conditions but not in the presence of a D_1R antagonist, 2) was observed on cone terminals, but not on cBC dendrites, following prolonged darkness at night, and 3) was minimal following prolonged darkness in the day. In the day, following application of dopamine and APB (mGluR6 agonist that blocks cone to ON-BC signaling), rabbit ON-cBCs produced opposite polarity (i.e., hyperpolarizing) surround responses that were blocked by gabazine. Gabazine increased the input resistance of

goldfish cones at night, but had minimal effect in the day.
Conclusions. These results suggest that 1) prolonged light adaptation increases D_1R activation, which elevates cAMP/PKA, so that $GABA_A$R expression and activity of ON-cBC dendrites are enhanced, producing ON-cBC surrounds via direct GABA-mediated HC input to ON-cBC dendrites, and 2) when the retinal clock elevates cAMP/PKA activity in cones at night by decreasing activation of their D_2Rs, $GABA_A$Rs are expressed and active on cone terminals to a greater extent than during the day when the clock activates the D_2Rs. When bright illumination in the day activates D_1Rs on cBCs, HCs use GABA to signal cBCs, but at night when it is dark and the retinal clock does not activate D_2Rs, HCs use GABA to signal cones.

Title: Direct inhibition onto retinal ganglion cells plays a critical role in surround inhibition and direction selectivity

Authors: *J. Y. HUANG[1], D. A. PROTTI[2]
[1]Discipline of Biomed. Sci., The Univ. of Sydney, Lidcombe, Australia; [2]Discipline of Physiol., The Univ. of Sydney, Sydney, Australia

Abstract: In the brain, the exquisite balance between excitation and inhibition is important in determining neuronal output. The response of the neuron is dependent on the integration of excitatory and inhibitory inputs and the level of activity of its surrounding networks. In this study, we examined the size tuning properties and direction selectivity of ganglion cells in whole-mount mouse retinae by doing dynamic-clamp recordings. Firstly, we assessed the effects of different levels of inhibition on spatial-tuning properties of ganglion cells. Light-evoked excitatory and inhibitory conductances recorded in response to different spot sizes were injected into 14 ganglion cells. The ratios of excitatory and inhibitory conductances injected varied between 1:0 and 1:2 (5 different combinations). Secondly, digitally synthesised directionally tuned conductances (modelled on physiological responses of ON-OFF direction-selective ganglion cells) were injected to elucidate the origin of direction selectivity in 32 cells. To test

whether or not direction selectivity can be achieved by varying the amplitude and timing of directional tuned excitatory and inhibitory conductance, we injected a family of excitatory and inhibitory conductance of different angles into 21 cells. After injection of light-evoked excitatory and inhibitory conductances of different stimulus sizes (ratio = 1:1), the neuronal responses generated by the onset of conductance exhibited characteristic area-response function displaying surround inhibition. Surround inhibition was present in all conditions of different ratios; with larger indices of surround inhibition as the level of inhibitory conductance injected increased. Comparison between responses to directionally tuned ON-OFF conductances with and without inhibition at the preferred direction showed stronger responses in the absence of inhibition. For conductances in the null direction, there was no/little response to the injection of control conductance but a much larger response after inhibition was removed. This clearly indicates that inhibition is vital in conferring direction selectivity. For the 21 cells tested with various amplitude and timing of directional tuned excitatory and inhibitory conductances, directional tuning of inhibitory conductances showed to be the critical factor determining direction selectivity in ganglion cells.

Title: Two-photon imaging of light-evoked calcium responses in bipolar cell axon terminals of the wholemount mouse retina

Authors: *M. CHEN[1], S. PARK[1], B. BORGHUIS[1], L. LOOGER[2], J. ZHOU[1]

Abstract: Bipolar cell (BC) axons release glutamate in the inner plexiform layer of the retina where they also receive inhibitory feedback input from amacrine cells. To make direct measurements of the receptive field properties of BC axon terminals, we used two-photon imaging to characterize light-evoked Ca responses at individual synaptic boutons of BCs in the mature mouse retina. The fluorescent calcium indicator protein GCaMP3 was expressed in On BCs following *in vivo* electroporation of a DNA construct encoding GCaMP3 under the mGluR6

promoter. In each retina, patches of On bipolar cells, including rod BCs and various subtypes of On cone BCs, were found to express GCaMP3. The morphology of individual GCaMP3-expressing BCs were characterized by reconstructing vertical stacks of two-photon images taken from the wholemount retina. These On BCs, especially rod BCs, often generated spontaneous Ca transients. They also gave robust responses to light flashes. The kinetics of the Ca responses to light flashes varied from subtype to subtype, with rod BCs showing a more sustained decay phase. The cone BCs showed either a sustained or a transient decay phase, depending on the cell type, and had a center-surround receptive structure. We also examined the light responses of BC terminal boutons that contacted the On starburst processes in ChATcre-td-tomato mice and of BC terminals that contact the dendrites of On-Off direction-selective ganglion cells (DSGCs) which were patch-clamped and filled with a red fluorescent dye. More than one type of On cone BC was found to make apparent contacts with the displaced starburst dendrites and gave robust responses to moving light-bar stimulation. The directional properties of the Ca responses at these BC axon terminals are currently under investigation, though preliminary experiments so far have not detected pronounced direction selectivity.

Title: The role of vGluT2 in non-image forming vision mediated by melanopsin-expressing retinal ganglion cells

Authors: *A. DELWIG, K. AHERN, M. M. LAVAIL, D. R. COPENHAGEN
Ophthalmology, UCSF, San Francisco, CA

Abstract: Retinal ganglion cells in the eye rely on glutamatergic neurotransmission to relay visual signals to the brain. These cells use vesicular glutamate transporter 2 (vGluT2) to sequester glutamate into synaptic vesicles. In the present study, we investigated the role of vGluT2 in visual signaling from melanopsin-expressing retinal ganglion cells (mRGCs). mRGCs mediate non-image forming responses to light including avoidance of light and light-induced distress ultrasonic vocalization in neonatal mice and pupillary light reflex (PLR) in older animals. We used conditional knockout of VgluT2 from mRGCs to examine these responses. We found that in neonatal mice, avoidance of light and light-induced distress vocalizations are completely dependent on vGluT2. In adults, loss of VgluT2 results in inability to fully dilate pupils in darkness and to stabilize pupil size. Loss of VgluT2 also results in decreased PLR and in increased delay to maximum constriction. Image-forming vision, evaluated by optokinetic response, was not affected in conditional vGluT2 knockout mice. We conclude that non-image forming vision in young neonates depends exclusively on vGluT2-dependent glutamatergic transmission from mRGCs. In adults, vGluT2-dependent glutamatergic signaling from mRGCs contributes most but not all of the light signals for the control of pupil size.

Title: A spiking retina model with cone opponency

Authors: *S. E. CHELIAN, N. SRINIVASA
HRL Laboratories, LLC, Malibu, CA

Abstract: Retinas are believed to contain much more sophisticated processing than previously imagined. Their mixed analog-digital signaling, space variant sampling, and gain control are unmatched even by today's most advanced imaging sensors. There have been several attempts to model retinal processing in both hardware and software. However, these models often compromise biological fidelity in favor of performance requirements. Furthermore, a detailed simulation of retinal processing constrains subsequent modeling of visual processing and sensorimotor control. Here, a new model is presented that matches several key functionalities

including cone opponency in a bio-plausible way. In particular, relative proportions and spatial distributions of cone receptors were taken from retinal imaging datasets. Horizontal cells pool responses from several light receptors following a scaling function that controls both receptive field size and density. Bi-polar cell center surround receptive field dynamics were modeled with the shunting or membrane equation with inputs coming from single light receptors and horizontal cells. Finally, habituative dynamics at the ganglion cell layer use the depressing synapse model to differentiate between parvo- and magno- cellular cells. Ganglion cell activations are also converted into stochastic spike trains. Tests compare this model to the Virtual Retina, a recent monochrome spiking retina model, and show improved scaling capabilities. An 845 frame sequence with 50 ms. per frame was extracted from the CASTLE virtual environment with various resolutions. Processing times and number of neurons used for the current model and Virtual Retina were recorded with 3 runs per image resolution. In comparison to Virtual Retina, the current model is faster both in aggregate (35.0% for 64x64 and 5.36% for 128x128 images) and on a per neuron basis (69.5% for 64x64 and 81.2% for 256x256). Thus, while maintaining bio-plausibility, the current model exhibits several retinal functionalities including cone opponency along with greater scaling performance. Future applications will include modeling thalamocortical visual computations as well as the control of virtual agents.

Title: Evidence for functional role of CB1 cannabinoid receptors in the mammalian cone pathway

Authors: *A. STRAIKER[1], L. PARDON[2], J. PATEL[3], S. VISWANATHAN[2]
[1]Indiana Univ., BLOOMINGTON, IN; [2]Optometry, [3]Indiana Univ., Bloomington, IN

Abstract: CB_1 cannabinoid receptor immunoreactivity has been documented in the vertebrate retina. We investigated the retinal function of transgenic mice lacking CB_1 receptors (CB_1-/-) or the enzyme monoacylglycerol lipase (MGL-/-) involved in the breakdown of 2-arachidonoyl glycerol (2AG), an endogenous cannabinoid.
Full-field photopic flash electroretinograms (ERG) were recorded with DTL electrodes, differentially between the two eyes from anesthetized (ketamine 80 mg/kg, xylazine 10 mg/kg) wild type (WT), CB_1-/- and MGL-/- mice using an ESPION system. Pupils were dilated with phenylephrine HCL (2.5%) and accommodation blocked with tropicamide (1%). The cornea was kept moist with methylcellulose (1%) under custom contact lenses. 0.6 to 171 (P) cd.s/m^2 test flashes were delivered on a 112 (P) cd/m^2 background using blue light (640 nm, 40 nm ½ band width).
ERG waveforms of WT, CB_1-/- and MGL-/- showed a- and b-waves that increased in amplitude with flash intensity. For the 171 (P) cd.s/m^2 test flash, the average a-wave implicit time of MGL-/- was 12.8 ms and shorter than those of WT (19 ms, $p<0.0013$) and CB_1-/- (21.8 ms, $p<0.00079$). The average b-wave implicit time of CB_1-/- was 87.3 ms and delayed relative to WT (54.3 ms, $p<0.00037$) and MGL-/- (32ms, $p<0.000072$). The b-wave of CB_1-/- also took a longer time to recover as indicated by the ½ band width of 129 ms relative to those of the WT (37 ms) and MGL -/- (27 ms). The b-wave of MGL-/- was followed by a large negative potential. The a- and b-wave amplitudes were not significantly different for the 3 groups. However, the intensity response function of the b-wave amplitude indicated a smaller semi-saturation constant [14 (P) cd.s/m^2] with a slope of 1.75 for CB1 -/- relative to WT [67 (P) cd.s/m^2, slope 0.83] and MGL -/- [20 (P) cd.s/m^2, slope 2.1].
The significant alteration in the photopic flash ERG responses of transgenic mice lacking CB_1 receptors or the enzyme MGL provide further evidence for a functional a role of CB_1 receptors and endogenous cannabinoids in retinal information processing.

Title: Differential expression of cannabinoid receptors CB1 and CB2 within the vervet monkey retina

Authors: *J. M. BOUSKILA, P. JAVADI, C. CASANOVA, J.-F. BOUCHARD, M. PTITO
Sch. of Optometry, Univ. of Montreal, Montreal, QC, Canada

Abstract: The presence of the cannabinoid receptor type 1 (CB1R) has been largely documented in the rodent and primate retinas in recent years. There is however some controversy concerning the presence of the CB2 receptor (CB2R) within the central nervous system. Only recently did CB2R has been found in the rodent retina. Certainly, the involvement of both cannabinoid receptors in cannabis-like effects seems to support the presence of CB2R in the retina. The aim of this study was twofold: 1) to characterize the distribution patterns of CB2R in the monkey retina and compare this distribution to that previously reported for CB1R and 2) to solve the controversy on the presence of CB2R in the neural component of the retina. We therefore thoroughly examined the cellular localization of CB2R in the vervet monkey (Chlorocebus sabeus) retina, using confocal microscopy. Our results demonstrate that CB2R, as CB1R, is present throughout the retinal layers with however striking dissimilarities. Double labelling of CB2R and glutamine synthetase shows that CB2R is restricted to Müller cell processes, extending from the internal limiting membrane with very low staining, to the external limiting membrane with heavy labelling. Furthermore, double labeling of CB2R and retinal markers allowed us to exclude possible CB2R expression in retinal neurons. We conclude that CB2R is indeed present in the retina exclusively in the retinal glia whereas CB1R is expressed mainly in the neuro-retina. These results extend our knowledge on the expression and distribution of cannabinoid receptors in the monkey retina, although further experiments are still needed in order to clarify their role in retinal functions.

Title: The influence of hepatocyte growth factor during phagocytosis of non-specific targets by retinal pigment epithelium

Authors: C. MARRA[1], J. BLAIZE[3], J. TACHJADI[3], *W. J. L'AMOREAUX[2]
[1]Biol., City Univ. of New York - Col. of Staten Island, Staten Island, NY; [2]Biol., City Univ. of New York - Col. of Staten Island, STATEN ISLAND, NY; [3]Biol., City Univ. of New York - Grad. Ctr., New York, NY

Abstract: Inhibition of outer segment (OS) processing by retinal pigment epithelium (RPE) has been linked to photoreceptor injury and retinopathy onset. Sub-retinal clearance by RPE is facilitated by specialized phagocytosis featuring both RPE-specific and traditional FCγγR mediated signaling cascades. As a result, RPE are capable of internalizing both specific and non-specific external targets. We believe that hepatocyte growth factor (HGF) activation of its cognate receptor (cMet) may play an integral role in RPE phagocytosis. Lack of cMet signaling results in impaired phagocytosis in macrophages. Phagosome formation triggered by Rac1 is as an essential contributor to RPE phagocytosis following activation by PI3K. Since PI3K phosphorylation occurs downstream of c-Met dimerization, we hypothesize that cMet activation is responsible for mediating both specific and non-specific phagocytic clearance by RPE.
To test our hypotheses, cultured ARPE-19 and RPE-J cells were grown to 70% confluence, prior to 24hr serum starvation. Post starvation, cells were exposed to various concentrations of HGF for 1, 20 or 60 min. or 24 hr before preparing for immunohistochemical investigation. Phosphorylated and total receptor (c-Met) and enzyme (focal adhesion kinase [FAK], PI3K) concentrations were targeted in an attempt to gauge the influence of exogenous HGF on expression levels. In a concurrent study, cells were challenged with fluorescently labeled E.coli or latex beads to evaluate binding and internalization immediately following exposure to exogenous HGF. Intensity values suggest that RPE respond maximally to concentrations of 25 ng/ml of HGF when compared to controls. Unsurprisingly, phosphorylated c-Met concentrations were not significantly altered after 24 hrs; however, immuno-detection data show a two-fold increase in c-Met phosphorylation after 20 min. of exogenous HGF exposure. Elevated HGF treatments also appear to increase binding of both fluorescently labeled challengers. Our findings suggest that RPE respond to increases of exogenous HGF concentrations by up-regulating its receptor and subsequent second messengers systems. In addition, our data show a significant increase of fluorescently labeled E. coli. Interestingly, when RPE are exposed to wortmannin (chemical antagonist of PI3K) prior to elevated HGF in vitro, biding and internalization of non-specific debris appear to be reduced. Taken together, these findings suggest that RTK cross-talk initiated by c-Met activation may be sufficient in mediating general uptake of external debris by RPE.

Title: The selective activation of group III metabotropic glutamate receptors subtypes produces different patterns of Gaba immunoreactivity and glutamate release in the retina

Authors: *E. GUIMARÃES-SOUZA, K. C. CALAZA
Neurobio., Univ. Federal Fluminense, Niterói, Brazil

Abstract: Glutamate is the major excitatory neurotransmitter in the retina, being released by photoreceptors onto bipolar cells which, in turn, release glutamate onto ganglion cells. Glutamate can activate both ionotropic and metabotropic glutamate receptors, which are widely distributed in the retina. Group III metabotropic glutamate receptors, with the exception of mGluR6, are mostly found in sublayers of the inner plexiform layer. Thus, we decided to investigate the role of the activation of group III metabotropic glutamate receptors on neurotransmitter release from cells in the chicken retina. Non-selective group III agonist L-SOP promoted a decrease in the number of GABA-positive cells in relation to the control, and also in the immunoreactivity found in all the sublayers of the inner plexiform layer. This effect was prevented by the non-selective group III antagonist MAP-4, by GAT-1 inhibitor (NNC-711) and by antagonists of ionotropic glutamate receptors (MK801 and DNQX). Under the superfusing conditions used, L-SOP did not alter endogenous glutamate release from retinal cells. VU 0155041, an mGluR4 positive allosteric modulator, reduced GABA-immunoreactivity in amacrine cells of the inner nuclear layer and in sublayers 2 and 4 of the inner plexiform layer, and also evoked an increase in the release of glutamate from retinal cells, and this effect was inhibited by calcium absence. AMN 082, a selective mGluR7 positive allosteric modulator, also decreased GABA-immunoreactivity in both inner nuclear layer and sublayers 1, 2 and 3 (OFF sublayers), and increased glutamate release, effect that was also inhibited by calcium absence. DCPG, an mGluR8 selective agonist, did not significantly alter GABA-immunoreactivity in inner nuclear layer cells and it did not alter glutamate release. However, it did significantly increase GABA-immunoreactivity in sublayers 4 and 5 (ON sublayers). The results suggest that mGluRIII are involved in the

modulation of glutamate and GABA release in the retina, and that each subtype might be responsible for regulating neurotransmitter release in different regions, maybe participating in distinct visual pathways. mGluR4 might be involved with starburst amacrine cell circuitry, while mGluR7 and mGluR8 might participate, respectively, in the OFF and the ON pathways.

Title: Morphology and distribution of tyrosine hydroxylase-immunoreactive cells in the developing gerbil retina.

Authors: H. IMADA[1], K. SAKAI[2], *E.-I. MIYACHI[1]
[1]Dept Physiol, Fujita Hlth. Univ. Sch. Med., Toyoake, Aichi, Japan; [2]Dept Anat, Fujita Hlth. Univ. Fac Clin. Engin, Toyoake, Aichi, Japan

Abstract: The morphology and distribution of the catecholaminergic neurons in the vertebrate retina have been examined with immunohistochemical technique by many researchers. The catecholaminergic retinal neurons in various animals were first found during a few days after birth. We have examined the development of catecholaminergic neurons in the gerbil retina by using antibodies against tyrosine hydroxylase, the enzyme that controls dopamine synthesis. Gerbils were given a dose of Nembutal, and then perfused transcardially with 0.1M phosphate buffer (PB; pH 7.4) for wholemount preparations, and with 0.1M phosphate buffer added to 4% buffered paraformaldehyde for sections. After removed eyeballs were frozen with a rapid jet of liquid carbon dioxide, they were cut with section of 16μm using a cryostat. The sections and wholemount preparations were incubated in rabbit anti-tyrosine hydroxylase (TH) for 24h at 4°C. They were examined by ABC (avidin-biotin-peroxidase complex) staining method. In this study, TH-immunoreactive (TH-IR) cells were first detected on the first postnatal day in lightly labeled somata located in the inner part of the cytoblast layer (CBL), and in fine, poorly branching dendrites extending toward the middle of the thin and immature IPL. We have found two kinds of TH-IR amacrine cells. The two types were clearly different in somata and stratification of TH-IR dendrites in the inner plexiform layer (IPL) at P (postnatal day) 7. One type (type A) of TH-IR cells have monostratified dendrites extending in the outermost layer of

the IPL, while the other type (type B) cells have dendrites extending in the middle of IPL. The type A somata were larger and more densely stained than those of the type B cells. The type A somata showed no significant growth, while the type B somata showed significant growth between P7 and P14 days. After P 14 little change was seen in the sizes of the type B somata. After P28, the diameters of type A somata did not overlap with those of the type B somata. The type B mean density decreased drastically between P7 and P28 days, while little change was seen in the number of the type A cells. These results suggest that two kinds of dopaminergic amacrine cells have different developmental properties in the developing gerbil retina.

Title: Muscarinic AChR activation affects sustained concentric ganglion cells' center-surround receptive field organization

Authors: *C. E. STRANG, Y. LONG, K. E. GAVRIKOV, K. T. KEYSER
VISION SCIENCES, Univ. Alabama Birmingham, BIRMINGHAM, AL

Abstract: Previous studies have demonstrated that muscarinic acetylcholine receptors (mAChRs) help to shape retinal ganglion cell response properties and that the reported effects of mAChR activation vary by ganglion cell type. Thus, the purpose of this study was to identify specific ganglion cell types whose response properties were affected by muscarinic activation. This portion of the study focused on the effects of m1-m4 mAChR activation on morphologically and physiologically identified ganglion cell subtypes. Rabbit eyecups were used for whole cell patch clamp recordings to test the effects of mAChR agents on ganglion cell light responses. Patch clamp recordings were used to identify brisk and sluggish sustained ON and OFF ganglion cells. Light responses were recorded before, during, and after the application of non-specific muscarinic agonist methacholine (Mcho). Muscarinic receptor antagonists, including pirenzepine

(PZP; m1), himbacine (m2/m4), and 4-diphenylacetoxy-N-methylpiperidine methiodide (4-DAMP; m3), were also applied to determine the contributions of specific mAChR subtype activation. Cell morphology was confirmed by injecting Lucifer Yellow. Retinas were further processed with antibodies against choline acetyltransferase to determine the stratification levels of the dendrites relative to the stratification of starburst amacrine cells.Muscarinic AChR activation and blockade affected the relative weighting of contributions to center and surround of ganglion cell receptive fields. Bath application of Mcho decreased the center On responses and increased surround inhibition of sustained ON cells. In contrast, Mcho application increased the center responses of sustained OFF cells and decreased surround inhibition. Specific mAChR subtype blockade had consistent effects on the light responses of sustained ON cells, for example Himbacine, PZP, and 4-DAMP all decreased the light responses suggesting that both excitatory and inhibitory mAChR subtypes contribute to shaping the center response. Differential effects of specific mAChR blockade on the light responses of sustained OFF cells suggesting that activation of excitatory and inhibitory mAChRs can change the relative weighting of center vs. surround components of the receptive field. Our data suggest that mAChR activation affects center responses through receptors expressed in the vertical pathway, and affects surround responses through receptors expressed on horizontal and/or amacrine cells. The activation of excitatory and inhibitory mAChR subtypes expressed in vertical and lateral pathways appeared to be essential for center-surround balance.

Title: Prostaglandin (PGF2α) suppresses TEA -sensitive K currents by decreasing conductance without changing voltage-dependency in isolated rat retinal ganglion cells

Authors: *T. YAMAMOTO[1], M. FURUTA[2], Y. NISHIMURA[3], M. KONDO[2], Y. UJI[2]
[1]Dept. of Neurophysiol., [2]Dept. of Ophthalmology, Mie Univ. Grad.Sch.Med., Tsu, Japan; [3]Dept. of Pharmaceut. Sci., Suzuka Univ. of Med. Sci., Suzuka, Japan

Abstract: The glaucoma is one of the most important disorders which lead to visual loss. It has been reported that Latanoprost, a prostaglandin F2α(PGF2α) analog, decreases intraocular pressure in glaucoma. It is also suggested that Latanoprost may protect retinal ganglion cells

(RGCs) against cell death in glaucoma. However, few studies have been reported on the effects of these drugs on the ionic currents in RGCs. We suppose that such protective effects of PGF2α-analog may be through a modulation of ionic channels in RGCs. In the present study, we identified RGCs by retrograde labeling with Fast Blue (FB). FB was injected into the superior colliculi in neonatal rats (3-8 days old) by a Hamilton syringe under cryoanesthesia. Two days after the operation,these rats were anesthetized with ether and decapitated. Enucleation of their eyes was performed and RGCs were enzymatically dissociated by trituration. Isolated RGCs were dispersed in the recording chamber and FB-labeled RGCs were identified under an epifluorescence microscope.
The effects of PGF2α on voltage-dependent and TEA-sensitive potassium currents (I_K) were analyzed by whole-cell patch clamp method. I_K was recorded in the Ca-free solution containing TTX(0.5μM) and 4-aminopyridine(4AP; 5mM). PGF2α suppressed TEA-sensitive K currents of the rat RGCs by 25~35 %. PGF2α also decreased conductance of TEA-sensitive K currents (control: 12.2±2.4nS; PGF2α: 8.0±1.9nS) without changing voltage-dependency of TEA-sensitive K currents.
The present study suggests the possibility that the modulatory action of PGF2α on RGC I_K may have some effect on the survival of RGCs under high ocular pressure.

Title: Origins of intrinsic signals in the retina of pigmented rabbits

Authors: *A. NADERIAN[1], L. BUSSIÈRES[1], S. THOMAS[1], F. LESAGE[2], C. CASANOVA[1]
[1]écol d'optométrie, Univ. De Montreal, Montreal, QC, Canada; [2]École Polytechnique de Montréal, Montreal, QC, Canada

Abstract: Intrinsic optical imaging is a technique that measures neuronal activity indirectly through the coupling between metabolic activity of neuronal populations and the blood supply. Intrinsic responses have been observed in the retina, but the factors determining these signals and their exact anatomical origin have not been clearly identified. The purpose of this study was to

characterize the intrinsic retinal responses and determine the anatomic origin of these signals. Retinal intrinsic optical imaging is performed using a modified fundus camera that captures the reflected light from the retina, illuminated by near infrared light (≈ 750 nm). Stimulation of the retina is performed by a brief spot illumination of green light (≈ 550 nm). Experiments were performed on anesthetized and paralyzed pigmented rabbits. Concurrent with the imaging acquisition, electroretinograms were also recorded to have control values of retinal activity. The experiments were performed in scotopic conditions and started after 30 min of adaptation. Experimental trials consisted of 24s recordings (10 Hz frame rate) and after 3s of baseline measurements, retinal stimulations (200 ms) were given.
Initially, the relation between stimulus intensity and responses amplitude was tested. A non-linear proportional relationship was found between intrinsic signal amplitude and the stimulation intensity used (27% increase from 1.5 to 2.5 log cd.sm-2). To begin studying the contribution of different retinal cell types in these responses, we inhibited sequentially the activity of each of the retinal layers using intra vitreous injections of pharmacological agents: tetrodotoxin (TTX) to inhibit the innermost retinal layer (ganglion cells, amacrine cells), 2-amino-4 phosphonobutyrate (APB) for inhibiting the ON pathway and cis-2,3-piperidinedicarboxylic acid (PDA) for inhibiting the OFF pathway of the retina. Two sequences of injections were tested: 1) TTX, APB and PDA or 2) TTX, PDA, and APB.
Preliminary data show that TTX decreased intrinsic signals amplitude by 20% and suggests a minimal role of ganglion cells in the genesis of intrinsic responses. In the first sequence of injections the amplitude of intrinsic signals decreased by 40% after injection of APB and an additional 46% reduction was observed after the injection of PDA. For the second sequence of injection, intrinsic responses were reduced by 46 % after the injection of PDA, while subsequent injection of APB decreased responses amplitude by only 11%. Our results suggest that the activity from cells located in the outer and middle layers of the retina are responsible for the intrinsic signals observed in the retina.

Title: Pathway specific activation of AMPAR subtypes on retinal ganglion cells

Authors: *R. S. JONES, R. C. CARROLL, S. NAWY
Neurosci., Albert Einstein Col. of Med., BRONX, NY

Abstract: In the retina, AMPA-type glutamate receptors (AMPARs) are expressed on a variety of cell types, including retinal ganglion cells (RGCs). Both the GluA2-containing, Ca^{2+}-impermeable AMPARs (CI-AMPARs) and the GluA2- lacking, Ca^{2+}-permeable AMPARs (CP-AMPARs) contribute to light-evoked responses in RGCs; however specific roles for each type are not well understood. Here, we investigated the conditions for activation of CI- and CP-AMPARs in the ON pathway by measuring the light-evoked IV relationship in mouse RGCs. We find that for dim light intensities CP-AMPARs are activated exclusively and as the light intensity is increased CI-AMPAR responses are recruited. Blocking reuptake of glutamate with TBOA during dim light IV measurements reveals a large CI-AMPAR component similar to what is observed with bright light without TBOA. These results suggest that CP-AMPARs are closest to presynaptic release sites and that CI-AMPARs are located father away in the synapse and can be activated by glutamate spillover, which may be generated in response to bright light. In addition, we wanted to determine whether the dim- versus bright- light dichotomy reflects a difference in rod versus cone AMPAR utilization. We found that in RGCs of mice lacking functional cones, rod pathway responses elicited over a range of light intensities carry a large CP-AMPAR component. However, in RGCs of mice lacking functional rods, cone pathway responses are almost exclusively driven by CI-AMPARs, save for the dimmest light intensities. This suggests that AMPAR subtypes are segregated in the postsynaptic membrane, which may enable rod and cone signaling pathways to activate distinct postsynaptic responses despite converging on the same presynaptic terminal.

Title: NMDA receptor expression and functional contributions to the extrinsic light response in intrinsically photosensitive retinal ganglion cells

Authors: *B. STAFFORD, K. Y. WONG
Ophthalmology and Visual Sci., Univ. of Michigan, Ann Arbor, MI

Abstract: Purpose: There are at least five different types of intrinsically-photosensitive ganglion cell (ipGC; M1-5), each with its own morphology and melanopsin-mediated (intrinsic) light response. In addition, ipGCs also receive rod and cone inputs, similar to other ganglion cell (GC) types, and these inputs generates an extrinsic light response in these cells. However, relatively little is known about the composition of the receptors used by ipGCs to encode rod and cone inputs. Most GC types express NMDA receptors (NMDARs), and, in the case of some types, use them in a contrast-dependent fashion to encode light responses. Other GC types express functional NMDARs, but, apparently, do not use them to encode light responses. Whether ipGCs express and/or use NMDARs to encode their extrinsic light response is unknown. Here, we examined the subunit-specific expression patterns of functional NMDAR subunits as well the contribution NMDARs make to the extrinsic light response in the ipGCs.
Methods: Retinas were isolated from dark-adapted mine in which ipGCs were selectively labeled with EGFP (Ecker et al. 2010). EGFP-labeled cells were visualized with 950nm laser on a multiphoton microscope and targeted for whole-cell recording. Under voltage-clamp conditions, responses to exogenous application of NMDA were recorded at a series of holding potentials. To determine subunit specificity, responses were recorded under control conditions and in the presence of ifenprodil (10 µM), a GluN2B subunit specific NMDAR antagonist. To study the NMDA contribution to the extrinsic light response, light-evoked responses (500 micron flashes of white light) were recorded from GFP+ cells under current-clamp conditions with either control conditions or with MK-801 added to the intracellular solution.
Results: So far we have examined NMDA expression in M1 ipGCs. M1 cells express functional NMDARs and activation of these receptors is sufficient to induce spiking in these cells. NMDARs contribute to the extrinsic light response in M5 ipGCs. When NMDARs are blocked intracellularly in M5 cells, light-evoked spike output is blocked.
Conclusions: Our findings indicate that some ipGCs express functional NMDARs. Further, we find that at least one type uses NMDARs to generate its extrinsic light response. Knowledge about how the extrinsic light response is generated in ipGCs will help create a more complete understanding of how rod/cone signals might interact with and/or modify non-image forming visual function of ipGCs.

Title: Differences in the expression of GABA-A receptor subunits, GABA-C and glycine receptors on bipolar types in primate retina.

Authors: *U. GRUNERT[1], C. J. ABBOTT[2], K. A. PERCIVAL[1]
[1]Ophthalmology, Univ. of Sydney, Sydney, Australia; [2]Devers Eye Inst., Portland, OR

Abstract: Background: GABA and glycine are the major inhibitory transmitters in the mammalian retina. Bipolar cells receive GABAergic and glycinergic synapses via multiple types of amacrine cells. Electrophysiological studies of rodent bipolar types suggested that the proportions of GABA and glycine receptors differ between different types of bipolar cells. Here we studied the distribution of $GABA_A$, $GABA_C$ and glycine receptors on different bipolar types in primate retina using immunohistochemistry.
Methods: Vertical cryostat sections through the retinas of macaque and marmoset monkeys were double labeled with antibodies against bipolar types and antibodies against $GABA_A$, $GABA_C$ and glycine receptor subunits. The density of immunoreactive puncta associated with bipolar cells was quantified using an image analysis program (Imaris). Five bipolar types (OFF-midget, DB3, DB4, DB6, and rod bipolar cells) were identified and the expression of the alpha1, alpha2, alpha 3 and gamma 2 subunits of the $GABA_A$ receptor, $GABA_C$ and the alpha 1 subunit of the glycine receptor was determined.
Results: $GABA_A$ and $GABA_C$ receptors were expressed by all bipolar types but at variable densities. The alpha 1 subunit of the $GABA_A$ receptor was most strongly expressed by OFF midget bipolar cells, whereas the alpha 3 subunit was most strongly expressed by the cone ON bipolar type DB4. $GABA_C$ receptors were most strongly expressed by rod bipolar cells and by the ON cone bipolar types DB4 and DB6. The alpha 1 subunit of the glycine receptor was mostly expressed by OFF midget bipolar and DB3 cells.
Conclusions: The differential expression of GABA and glycine receptors on bipolar types in primate retina is consistent with the idea that inhibition varies between different bipolar pathways.

Title: A ganglion cell in the mouse retina with nearly linear light response

Authors: *B. KRIEGER, J. SANES, M. MEISTER
Harvard Univ., Cambridge, MA

Abstract: The notion that the mammalian retina is a simple spatiotemporal pre-filter of the visual scene has started to be replaced with the idea that the retina performs preprocessing to extract specific image attributes. In recent years a number of retinal ganglion cell (RGC) types have been described as feature detectors that selectively respond to distinct visual aspects such as movement in a particular direction or looming objects. Here we report one RGC type that departs substantially from this theme.
The so-called W7 RGCs are labeled in a transgenic mouse line produced by random insertion of a gene for a fluorescent reporter. They represent a natural RGC type as assessed by their regular spacing in a mosaic covering the retina. In constant uniform light the W7 cells fire at an elevated baseline rate (10-20 Hz) with very regular inter-spike intervals, unlike many other mouse RGCs that require a threshold stimulus to fire at all. The W7 cell has a sustained Off response with a classic center-surround receptive field. It modulates the firing rate nearly linearly with the stimulus, except for short periods of silence in bright light. As a result it can report even weak stimuli, down to a few percent contrast. Further receptive field modeling suggests that the W7 cell pools input from Off bipolar cells, each of which has an antagonistic surround, with only mild rectification at the bipolar cell synapse.
These characteristics of the W7 cell suggest that it plays a complementary role to the more specialized types of feature detectors in the mouse retina. We will discuss in particular their function in encoding the natural stimuli that the retina encounters during locomotion.

Title: Learning invariances from retinal inputs

Authors: G. GREENE[1,2], E. EHRHARDT[1], T. GOLLISCH[3,2], *T. WACHTLER[1,2]
[1]Dept. Biol. II, Ludwig-Maximilians-Univ Munich, 82152 Planegg-Martinsried, Germany; [2]Bernstein Ctr. for Computat. Neurosci., Munich, Germany; [3]Dept. of Ophthalmology, Georg-August-Universität, Göttingen, Germany

Abstract: The visual cortex is known to develop representations which are invariant to certain stimulus features. These include low level features, for example the phase of an oriented grating, as well as higher level features such as gaze direction. Numerous studies have proposed that such representations are learned by exploiting differences in the timescales over which different features persist. In general, however, these studies use raw visual stimuli as input to cortical networks, and so ignore the effects of spatio-temporal signal processing in the retina. We investigate how retinal processing contributes to the learning of invariances in visual cortex, in particular the development of complex cell properties in V1, and image stabilization under fixational eye movements.

We present a model retina with different cell types that captures both the mostly linear behaviour of midget cells, as well as much of the non-linear behaviour of parasol cells. We then use this model retina as an input layer to a cortical invariance learning network that exploits a self-organised topographical structure to learn selectivity to slowly varying features (Michler et al, J Neurophysiol 2009).

Under continuously drifting stimuli this model learns complex cell-like representations. We find that cells receiving parasol cell input display a higher degree of phase invariance than those trained on midget cell input, while remaining orientation selective. When trained on a combination of midget and parasol inputs, the complex units tune preferentially to parasol cells. Furthermore, we show how, using a non-linear combination of midget and parasol inputs, a cortical network may learn to distinguish local and global image shifts, generating a gaze invariant representation.

Our results suggest that retinal non-linearities - such as those associated with parasol ganglion cells - facilitate the learning of complex cell properties and, together with the bifurcation of

retinal inputs into parvo-cellular and magno-cellular pathways, support image stabilisation under fixational eye movements.

Title: Fixational eye movements increase acuity in a retinal Bipolar-Amacrine-Ganglion circuit model

Authors: *J. S. SHERFEY[1,2,3], A. YAZDANBAKHSH[2]
[1]Boston University, Sch. of Med., Boston, MA; [2]Cognitive and Neural Systems, Ctr. for Computat. Neurosci. and Neural Technol., [3]Mathematics, Boston Univ., Boston, MA

Abstract: The mammalian retina contains at least 11 Bipolar (B), 25 Amacrine (A), and 20 Ganglion (G) cell types, each with characteristic dendritic morphologies, stratification patterns, and physiological characteristics, all connected in complex, highly-structured networks with diverse electrical and chemical synapses. While the retina has been widely considered a simple interface between environment and brain with filters, relays, and image compression, the diversity of anatomical and physiological features present in the retina raises an important unanswered question: is retinal complexity an epiphenomenon of natural selection's lack of design or does it serve a purpose, endowing the retina with unforeseen computational capacities, previously masked by technological and experimental limitations.
To address this question, we developed a mathematical model of a B-A-G cell network with eccentricity-dependent receptive fields and focused on the poorly understood issue of how retinal processing differs in the presence and absence of involuntary fixational eye movements

(microsaccades and drift). We defined a spatio-temporal modulation index to characterize the ability of G-cells to resolve different spatial and temporal frequencies. Model parameter values were guided by data on anatomical and physiological properties of midget B-cells, parvocellular G-cells, and electrically-coupled, wide-field A-cells. The rates, extents, and directions of microsaccadic and slow drift movements were in the range of those reported for mammals. Our results indicate that there exists a biologically-motivated parameter set within which the model with fixational eye movement increases retinal sensitivity, lowering the detection threshold for sinusoidal gratings over a range of spatial frequencies (cycles per degree) and temporal flicker rates without the need for extra-retinal aid. Our future studies will investigate the mechanisms that underlie this potential image enhancing feature of fixational eye movements and the model retinal substrates on which it depends. Additionally, our current model has the capacity with parameter changes to implement symmetrical versus asymmetrical connectivity, the lack or presence of direction selectivity, and propagation delays. Simulating these conditions will enable us to further explore the computational implications of differences between mammalian retinas from rabbit to macaque and to offer predictions for future retinal experiments.

Title: Parallel nonlinear processing at retinal bipolar-ganglion cell synapses

Authors: *D. A. BUTTS[1], Y. V. WANG[2], J. B. DEMB[2]
[1]Dept. of Biol., Univ. of Maryland, COLLEGE PARK, MD; [2]Dept. of Ophthalmology and Visual Sci. and Dept. of Cell. and Mol. Physiol., Yale Univ., New Haven, CT

Abstract: Nonlinear processing in the retina has been implicated in a variety of response properties important for natural vision, including contrast adaptation and precise spike timing. Furthermore, nonlinear processing occurs simultaneously across parallel processing streams, which converge onto ~20 different types of output neurons, the retinal ganglion cells (RGCs). RGC types can be distinguished by both their morphology and response properties. To better understand the synaptic mechanisms driving parallel processing across RGC types, we recorded excitatory currents from four RGC types in the in vitro mouse retina during temporal white noise

stimulation of different contrasts. Standard linear-nonlinear (LN) characterizations of the currents revealed different levels of contrast adaptation across cell types. However, the LN model failed to capture transient components of the currents. Inspired by nonlinear modeling previously applied to explain temporal precision in spike train outputs, we constructed models structured to simulate potential physiological mechanisms such as presynaptic inhibition and synaptic depression, and fit them to the observed synaptic currents. We found that the currents recorded in most RGC types were well described by excitation combined with a delayed, multiplicative suppression, which explained the transient features not captured by the LN model. Furthermore, a single set of parameters that captured these transient features also explained the current responses across contrast, outperforming separate LN models fit at each contrast. There were also consistent differences in the nonlinear architecture across RGC types, potentially explaining the diversity in computations across parallel processing streams.

Title: Adaptation to stimulus mean and variance in the Limulus lateral eye

Authors: *C. PASSAGLIA, T. VALTCHEVA, D. COVERT
Univ. of South Florida, TAMPA, FL

Abstract: The vertebrate eye has been shown to dynamically adjust the sensitivity of its output neurons (retinal ganglion cells) to changes in luminance mean and variance though a collection of cellular and synaptic mechanisms distributed across the retinal network. Luminance mean adaptation has also been demonstrated in the output neurons of the invertebrate eye (eccentric cells), and the aim of this study was to investigate whether the homology in visual processing extends to luminance variance adaptation as well. Prior work on the lateral compound eyes of horseshoe crabs suggests that it does not but those studies did not employ a white noise stimulus, which has been effective at revealing contrast gain controls in the vertebrate eye. The spike trains of individual eccentric cells were thereby recorded from live horseshoe crabs to white noise stimuli of varying contrast delivered to optically-isolated ommatidial receptors. The stimulus was also input to a cell-based model of the Limulus lateral eye that can accurately simulate the eye's

response to behaviorally-relevant underwater movies. Linear-nonlinear models estimated from the spike output of model cells were unaffected by stimulus contrast, consistent with the longstanding idea that the retina is fairly linear at a given operating point. However, linear-nonlinear models estimated from the spike output of eccentric cells decreased in gain with increasing contrast of white noise, suggesting a heretofore unknown mechanism of contrast adaptation may operate in the retina. Given the simple organization of the horseshoe crab eye, determining whether this mechanism is distinct from those known to mediate light adaptation has broad implications to vision research.

Title: Parallel pathways for information processing in the retina

Authors: *J. GJORGJIEVA[1], H. SOMPOLINSKY[1,2], M. MEISTER[1]
[1]Ctr. for Brain Sci., Harvard Univ., Cambridge, MA; [2]Interdisciplinary Ctr. for Neural Computation, Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: Over 20 different ganglion cell types have been identified in the mammalian retina that represent parallel channels of information transmission. Each population of ganglion cells covers the entire visual field and sends a different transformation of the observed image to higher brain areas. We want to understand the origins and functional implications of this diversity. Efficient coding theory postulates that the early visual system is organized so as to transmit image information to the brain most efficiently given the statistics of natural scenes, constraints from sensory noise, and metabolic limits on neural activity. Early applications of the theory treated the retina as a linear spatial filter and derived successful predictions for the center-surround receptive fields of retinal ganglion cells. However, this theory cannot account for the splitting of the visual signal into 20 parallel pathways. Furthermore, it is apparent that the computations performed by many ganglion cells are highly nonlinear. By incorporating this new knowledge into the efficient coding framework we are exploring the constraints and possible

benefits of the diversification among retinal pathways.
A prominent instance of nonlinear pathway splitting in the retina involves the ON/OFF dichotomy. The ON and OFF channels differ in their polarity of responses to light and dark increments in a visual scene. We quantified the information gain in a system with two cell types of opposite light responses, ON and OFF, and compared it to a system where both cells are ON type. Both systems are constrained by the total firing of the cells and by Poisson noise in their spike count. The system with ON and OFF cells is more efficient. However, the difference becomes notable only when the stimulus distribution is sparse, namely when strong light increments or decrements are rare.
We also examined the diversification of ON-OFF direction selective cells in the retina. These neurons respond to moving stimuli traveling in one of the four cardinal directions, but not in the opposite direction. First we considered the encoding of a single stimulus parameter, the direction of movement, by a population of cells constrained as before by the total firing rate. For an intermediate range of firing rates, the optimal distribution of direction tuning curves around the circle is not uniform, at the expense of biasing information transmission to selected stimuli. We also analyzed what solutions emerge when one considers encoding of a second stimulus component, the stimulus velocity. This work will help us understand the constraints and consequences that have shaped the evolution of multiple pathways in the retina.

Title: Dendritic NMDA spikes in retinal direction selective ganglion cells

Authors: *A. POLEG-POLSKY, J. S. DIAMOND
NIH, Bethesda, MD

Abstract: Direction selective ganglion cells (DSGCs) in the retina reliably detect direction of movement of visual stimuli over a wide range of stimulation conditions. Direction selectivity (DS) in DSGCs depends on directionality shaped synaptic input from bipolar and starburst amacrine cells. However, the mechanism by which synaptic information is processed in DSGCs to generate DS spike output is presently unclear. To examine this question we mimicked bipolar activation by focal electric stimulation near identified dendritic processes of DSGCs and

recorded EPSPs from the somas. We found that the response to stimulation was highly nonlinear - while low intensity stimuli evoked EPSPs which were less than 4mV in size and scaled linearly with stimulation intensity, stronger stimuli generated EPSPs with average amplitude of 7.9±0.4mV, which were 211±36% above linear prediction. Dendritic calcium imaging at the location of stimulation revealed that the supralinear responses were accompanied by an increase in the dendritic calcium signal which was restricted to ~30µm region around the stimulation site. Application of NMDAR blocker AP5 blocked the supralinear responses and significantly reduced dendritic calcium signals. Further addition of AMPAR blockers completely abolished recorded responses.
In agreement with synaptic stimulation experiments, we found that NMDARs have a significant role in shaping the light responses of DSGCs; AP5 reduced both the amplitudes of subthreshold EPSP responses and the number of action potentials by about 50% for visual stimulations with stationary spots and moving bars. However, the reduction in the number of action potentials was similar between the null and preferred directions, and therefore the DS index was not significantly affected by NMDAR blockers. We conclude that excitatory inputs to DSGCs can generate NMDAR dependent regenerative events (NMDA spikes) which in turn amplify firing in DSGCs.

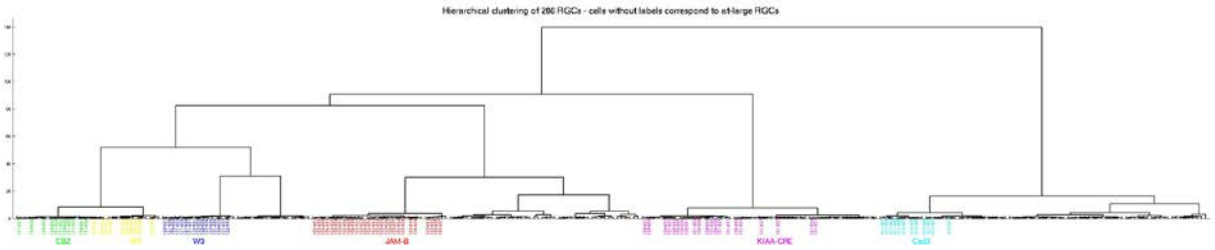
Title: Combining morphology and genetics towards a solution of the cell type identification problem



Authors: *U. SÜMBÜL[1], S. SONG[2], M. BECKER[3], K. MCCULLOCH[3], R. H. MASLAND[3], S. SEUNG[1]
[1]Brain & Cognitive Sci., MIT, Cambridge, MA; [2]Tsinghua Univ., Beijing, China; [3]Massachusetts Eye and Ear Infirmary, Harvard Med. Sch., Boston, MA

Abstract: Identifying the circuit elements is a crucial step towards mastery of neural circuits. Advances in genetic engineering have made it possible to image certain genetically defined components in some systems. Yet, the gene-to-cell type matching is not one-to-one in general and the cell type identification problem remains elusive for most meaningful circuits. The retina

has a well established morphological organization and a number of genetic labels have emerged recently. Two cells can belong to the same type only if they receive input from the same set of retinal cell types. For retinal ganglion cells(RGCs), this implies a close matching of stratification patterns. We characterized the stratification specificity of genetically defined RGC types at the resolution of imaging, with the starburst amacrine cell dendrites (ChAT bands) as fiducial marks. This information is used for classification. Genetic labels guide the inclusion of further morphological features, creating a hierarchy of such features, and ultimately a classification of cell types.

Convolutional neural networks are used to enhance the image quality. The arbors are traced semi-automatically using the Simple Neurite Tracer of the FIJI software package. The ChAT bands are detected automatically, quasi-conformally mapped to two parallel planes, and used to unwarp the RGC arbor trace in the wavy tissue. The stratification profiles of different RGCs are registered against each other using the flattened ChAT bands. Further morphological features are added by calculating those features within a moving thin in-plane slice, thus creating a continuum in depth for every feature.

We obtained the stratification profiles of more than 280 genetically defined RGCs including JAM-B, CB2, W3, W7, KIAA-CRE, Cad3 lines, and RGCs of unknown types from GFP-M animals. The stratification of known cells was remarkably precise, with submicron standard deviations of the peak plane. Hierarchical clustering was consistent with the available genetic labels, and suggests identities for the at-large RGCs, where there are no known genetic markers.

Title: A stationary spatial representation of moving edges in a population of motion sensing cells in the retina

Authors: *S. TRENHOLM[1], V. BALASUBRAMANIAN[2], D. SCHWAB[3], G. B. AWATRAMANI[4]
[1]Dalhousie University/University of Victoria, Victoria, BC, Canada; [2]Univ. of Pennsylvania, Philadelphia, PA; [3]Princeton Univ., Princeton, NJ; [4]Univ. of Victoria, Victoria, BC, Canada

Abstract: Introduction
The point-by-point mapping of visual space on the retina is critical for creating a realistic representation of the world. However, the slow transduction of information by the early visual system poses a serious challenge for coding moving stimuli. During the 50-100 ms response latency of second order retinal neurons, moving objects can cover a substantial distance. The visual system must therefore compute delays and dynamically update the spatial map to accurately localize objects. Here we show that such a computation is made by a population of directionally selective ganglion cells (DSGCs) within the retina, providing insights into the biophysical mechanisms underlying this process.
Methods
We recorded responses to moving stimuli from electrically coupled and uncoupled ON-OFF DSGCs (cDSGCs and uDSGCs) and reconstructed their dendritic arbors using 2-photon techniques.
Results
In response to moving stimuli (~200-2000 um/s), the position where uDSGCs first detected the leading edge shifted in space in a velocity-dependent manner, consistent with a fixed transduction delay (i.e. the edges of faster moving stimuli initiated responses further in space compared to slower moving edges). Remarkably, cDSGCs registered the leading edge at nearly the *same* spatial location (~150 μm *before* the nearest dendrite) over the 10-fold range of velocities tested. The ability to code moving edges at a relatively stationary location was found to require lateral interactions. When stimuli were presented locally over the cDSGC (400 μm mask), these cells lost their ability to compensate for delays, and the location at which edges initiated responses drifted in space as a function of velocity, similar to uDSGCs. A similar trend was observed when gap junctions were pharmacologically blocked (18β-glycyrrhetinic acid), suggesting that these were required for mediating lateral interactions. Finally, we constructed a mathematical model to demonstrate that a velocity-dependent increase in gap junction-mediated signals from neighbouring cells can endow cDSGCs with the unique ability to encode a veridical spatial representation of moving edges in the retina.
Conclusions
A population of DSGCs in the retina dynamically corrects the representation of moving stimuli

online to remove processing latencies via a novel mechanism involving gap junctions. The new mechanism allows the retina to convey the actual spatial coordinates of moving objects, via retinotopic connections, to higher visual centres. This active updating of the spatial map at the level of retinal ganglion cells likely aids the accurate and rapid localization of objects moving in space.

Title: Genetic analysis of visual circuits controlling image stabilization

Authors: *O. S. DHANDE[1], M. E. ESTEVEZ[2], R. N. EL DANAF[1], L. QUATRROCHI[2], P. L. NGUYEN[1], D. M. BERSON[2], A. D. HUBERMAN[1]
[1]Neurosciences Department, Univ. of California San Diego, La Jolla, CA; [2]Dept. of Neurosci., Brown Univ., Providence, RI

Abstract: As the head moves, retinal motion signals drive compensatory eye movements that stabilize the retinal image to optimize visual performance. A critical relay for such motion signals is the accessory optic system (AOS), a collection of midbrain nuclei that receive visual inputs from On-type direction selective retinal ganglion cells (ON-DSGCs). Through an anatomical screen, we discovered a transgenic mouse line with GFP expression largely confined to ganglion cells innervating the AOS, paving the way to detailed structure-function relationships

of AOS circuits. Retinofugal labeling in this mouse line is largely restricted to the medial terminal nucleus and the nucleus of the optic tract; except for sparse labeling in the lateral geniculate nucleus and superior colliculus, other retinal targets lack substantial labeling. Intracellular dye fills and patch recording showed many GFP cells were ON-DSGCs, with characteristic form, and with all three canonical directional preferences. However, bistratified cells resembling ON-OFF DSGCs as well as non-directional selective cells were also encountered. Our results suggest that AOS nuclei stabilize images based on inputs received from both canonical ON-type DSGCs, but that other RGC subtypes may also contribute. Genetic tools such as those described here should prove valuable for parsing the function, structure, development and plasticity of defined visual circuits.

Title: Using segregated on and off leaflets in the ferret lateral geniculate nucleus to explore push-pull circuitry

Authors: *V. SURESH[1], J. WONG[1], F. SOMMER[2], J. HIRSCH[1]
[1]Biol. Sci., USC, Los Angeles, CA; [2]Univ. of California, Berkeley, Berkeley, CA

Abstract: En route to the primary visual cortex, visual information coming from the retina is influenced by local thalamic circuits in the lateral geniculate nucleus (LGN). Receptive fields of relay cells in the LGN are made up of concentrically arranged subregions that have opposite preference for luminance contrast, On or Off. Furthermore, within each subregion there is a ‘push-pull’ arrangement of excitation and inhibition for stimuli of reverse contrast. Push-pull has been implicated in linearizing the response profile of relay cells, playing an important role in promoting efficient detection of local contrasts and decreasing sensitivity to redundancies in the stimulus. Past studies have postulated that push-pull is generated by circuits that operate as follows: preferred stimuli evoke feed forward excitation from the retina whereas stimuli of the reverse contrast elicit feed forward inhibition generated by local interneurons having the opposite stimulus preference. In species commonly used to study visual processing, On and Off cells are

intermingled in the LGN, making it difficult to study On and Off circuitry. However in the ferret LGN, cells within the principal laminae are separated according to their preference for On or Off stimuli. This segregation into On and Off leaflets makes the ferret a promising model system to study the structure of On and Off circuits. Hence, we first investigated whether ferret relay cells show a push-pull organization of excitation and inhibition. Different hypothetical circuits that might underlie relay cell responses are listed: 1. Relay cells having dendrites spanning across leaflets could receive inhibition from interneurons residing in the sublamina selective for stimulus of the opposite sign. 2. Relay cells that do not cross leaflet boundaries could derive inhibition from the projections of interneurons in the adjoining leaflet. 3. Alternatively, there could be a mechanism by which interneurons within a leaflet provide inhibition to relay cells in its layer by converting the sign of its retinal input; for example, an interneuron receiving On retinal input would provide Off inhibition. We have begun to investigate these scenarios using dye-filled pipettes to make whole cell recordings from neurons in the ferret LGN. Our immediate goal was to map receptive fields there and explore spatial arrangements of excitation and inhibition within subregions. We have found that relay cells with dendrites that span leaflets have push-pull responses and are currently exploring responses in other morphological populations of cells.

Title: Flicker modulation isolates the magnocellular layers of the human lateral geniculate nucleus

Authors: *J. D. VIVIANO[1], K. A. SCHNEIDER[1,2]
[1]Dept. of Biol., [2]Ctr. for Vision Res., York Univ., Toronto, ON, Canada

Abstract: The lateral geniculate nucleus (LGN) is composed of multiple neural populations with distinct retinal inputs and thus stimulus response properties. The magnocellular (M) and parvocellular (P) layers receive differ in response properties on several stimulus dimensions,

including color, contrast, spatial frequency, and temporal frequency. We sought develop an experimental paradigm to robustly differentiate between these two cell types in the human LGN using functional magnetic resonance imaging (fMRI). Participants were scanned using a Siemens Trio 3T MRI scanner and 32-channel head coil in York University's Neuroimaging Laboratory. Anatomical regions of interest (ROIs) were manually generated for the LGN and surrounding thalamic nuclei by manually tracing 4 hours of interpolated proton density weighted images. fMRI scans utilized a EPI sequence with 19 coronal slices, 2 mm thick, with a 128 matrix and 192 mm field of view resulting in an in-plane resolution of 1.5 mm2 [TR = 2 s, TE = 42 ms, flip angle = 90^0]. Ten scans were acquired per participant, who fixated on a contrast-reversing rotating hemi-field. Contrast reversal modulated between 2 Hz - 30 Hz at a frequency independent from rotation. Scans were co-registered, linear detrended, averaged and analyzed with a Fourier transform. The flicker modulation activated only a portion of the LGN that was activated by the retinotopy stimulus. By coregistering the functional data to the high-resolution anatomical ROIs, we were able to determine that the flicker modulations were confined to the ventral surface and M layers of the LGN. In sum, we have developed a temporal frequency paradigm that specifically isolates the M layers of the human LGN.

Title: Plasticity inside and outside critical period: Time-course and effects of ligth deprivation on the retinocollicular reorganization induced by monocular enucleation

Authors: *P. TRINDADE[1], A. T. GOMES[1], H. R. MENDONÇA[1], A. C. FARIA-MELIBEU[1], P. CAMPELLO-COSTA[1], R. LINDEN[2], C. A. SERFATY[1]

Abstract: AIM: Several types of injury are able to induce plasticity of intact circuits in the central nervous system. Monocular enucleation is a widespread model to study injury-induced plasticity that has been used in the past 40 years for the understanding of sensory processing in visual system. However, little is known about the mechanisms involved in plastic reorganization induced by monocular enucleation and the time course of these plastic events inside and outside the critical period. Therefore, we decided to investigate the time course of monocular enucleation-induced plasticity on retinocollicular axons of the remaining eye within and outside the critical period and the effect of light deprivation.
METHODS: Lister Hooded rats were submitted to monocular enucleation on postnatal day ten (PND10), PND21 or PND70 and maintained through different periods after surgery. After eye enucleation at PND21, some animals were kept in dark rearing during 24h or 1 week. Animals received intraocular injections of peroxidase or cholera toxin as anterograde tracers in order to map the topography of ipsilateral axons from intact eye.
RESULTS: During the critical period (PND10), monocular enucleation induced an intense sprouting of intact ipsilateral axons 12 hours after injury. This expansion was maintained up to 1 year after enucleation. At PND21, a phase that marks the end of retinocollicular critical period, monocular enucleation also induced an intense sprouting of intact axons 12 hours after injury. However, this sprouting decreased progressively until 6 months after injury. At PND70 we also detected a robust sprouting 12h after monocular enucleation that was reverted 1 week after. Animals subjected to light deprivation after a monocular enucleation at PND21 continued to exhibit an intense sprouting 24h after injury. However, we observed maintenance of this sprouting one week after enucleation at PND21.
CONCLUSION: Together our results indicate that, contrary to what the literature has been proposing, the plastic capacity of neurons in response to injury is present and strong even after the critical period. It also suggests that the elimination of topographically unrelated fibers appears to depend on visual experience. However, the sprouting induced by enucleation was not dependent on the visual experience.

Title: Inhibition of calcineurin and microglial activation alter plasticity of intact retinocollicular pathway following monocular enucleation

Authors: *C. A. SERFATY, L. S. CHAGAS, P. TRINDADE
Neurobio., Federal Fluminense University, Inst. De Biologia, Dept. Neurobiologia, Niteroi, Brazil

Abstract: Lesions to the developing central pathways are able to induce rapid plasticity of intact axonal populations that undergo a rapid compensatory growth during the critical period of development. At latter stages, lesions are able to induce slower and more limited plastic responses. Calcineurin is a serine-threonine phosphatase involved both in synaptic plasticity and microglial-induced inflammatory responses. We used a model of monocular enucleation to study the plastic response of ipsilateral retinocollicular axons from the intact eye in order to address the role of calcineurin and microglial cells in the plasticity that takes place in the collicular visual layers. Therefore we compared the blockade of calcineurin activity and the direct blockade of microglial activation in this form of compensatory plasticity during early postnatal development. Between postnatal days (PND) 7-10 rats were given systemic injections of cyclosporine A (CsA - 10mg/kg), a calcineurin inhibitor or vehicle. At postnatal day 10 (PND10), rat pups were submitted to a monocular enucleation under isoflurane anesthesia. At the same time an intravitreal HRP injection was made in the intact eye to label the ipsilateral axonal population to the denervated superior colliculus. A 24h survival followed both enucleation and axon tracing experiments. Systemic CsA administration inhibited the sprouting of intact ipsilateral axons following a monocular enucleation. CsA also inhibited microglial activation as demonstrated by reduction in immunofluorescence of Iba-1 and IB-4 in the superior colliculus contralateral to eye enucleation. To directly access the role and timing of microglial cells activation in the sprouting reaction, we tested either a microglial inhibitor, minociclin (125 mg/kg, sc) or CsA (50 mg/kg) administered four hours after the enucleation procedure. Both treatments were able to inhibit the sprouting of the ipsilateral pathway after a monocular enucleation. The data suggest that calcineurin-induced microglial activation is required for the lesion-induced plasticity of central visual pathways.

Title: Ultrastructure of mouse tectogeniculate terminals

Authors: N. ZHOU[1], T. E. KRAHE[2], C. W. D. JURGENS[2], W. GUIDO[2], *M. E. BICKFORD[1]
[1]Univ. Louisville Sch. Med., LOUISVILLE, KY; [2]Anat. and Neurobio., Virginia Commonwealth Univ. Med. Ctr., RICHMOND, VA

Abstract: The mouse dorsal lateral geniculate nucleus (dLGN) is a model system for the study of thalamic circuits. As in other species, the synaptic terminals of the mouse dLGN have been classified into four main categories: large profiles with round vesicles and pale mitochondria (RLP profiles; retinogeniculate terminals), small profiles with round vesicles and dark mitochondria (RSD profiles; corticogeniculate and cholinergic terminals), and GABAergic axon (F1 profiles) and dendritic terminals (F2 profiles). However, whether projections from the superior colliculus (SC) to the dLGN fit one of these categories remains unknown. The ultrastructure of tectogenicualte terminals has been difficult to identify because the injection of traditional tracers into the SC can also label retinogeniculate terminals. To specifically label tectogeniculate terminals, we injected a viral vector into the SC that induced the expression of the red fluorescent protein TdTomato. After a 10 day survival time, TdTomato was robustly expressed in SC neurons as well as their axon terminals in the dLGN, pretectum, lateral posterior nucleus and ventral lateral geniculate nucleus. Within the dLGN, TdTomato-labeled axons were distributed adjacent to the optic tract (lateral shell). This region is the primary recipient zone for a number of identified retinal ganglion cells that respond to the direction of movement. The TdTomato was tagged with a DsRed antibody, horseradish peroxidase, and a diaminobenzidine reaction. The tissue was then processed for electron microscopy. Thus far, we have examined a total of 113 tectogeniculate synapses. The tectogeniculate terminals were of medium size (mean area 0.48 um^2); i.e. larger than RSD profiles (mean 0.22 um^2), but smaller that RLP profiles (mean 1.33 um^2). Similar to retinogeniculate terminals, tectogeniculate terminals contact relatively large caliber dendrites (mean 0.84 um^2), many of which extend small protrusions into the presynaptic terminal. In tissue stained for the type 2 vesicular glutamate transporter (vGLUT2, a marker for retinogeniculate terminals) confocal microscopy indicated that tectogeniculate terminals are closely associated with retinal terminals. This association was confirmed at the ultrastructural level; tectogeniculate terminals were often located adjacent to RLP profiles. Our results indicate that tectogeniculate terminals form a fifth category of dLGN synaptic profiles, and the lateral shell may serve as a point of convergence for the integration of retinal and tectal signals involved in the processing of motion direction.

Title: Mechanisms governing the response of identified neurons in the superficial layers of the mouse superior colliculus to visual stimuli

Authors: *S. D. GALE, G. J. MURPHY
Janelia Farm Res. Campus, HHMI, Ashburn, VA

Abstract: The diversity and specificity with which individual neurons respond to features of sensory cues has been characterized exhaustively via extracellular recordings of neural activity in vivo. By contrast, the synaptic connectivity and biophysical properties that determine the set of stimuli to which neurons do and do not respond remains largely unclear.
To fill this gap in understanding we have focused on the mechanisms governing signal processing in the superficial layers of the superior colliculus (SC). Neurons here can be grouped into several distinct classes on the basis of (1) morphological features or (2) the specificity with which they respond to the size, speed, and/or direction of visual cues. We used juxtacellular recording and labeling in mice to determine to what degree distinct morphological classes of SC neurons exhibit distinct sensitivities to stimulus characteristics. Complementary whole-cell patch clamp recordings performed in slices, paired with activation of channelrhodopsin-2 (ChR2) expressed in subsets of retinal ganglion cells (RGCs) that project to the SC, enables us to assess the source of synaptic input that specific SC cell types receive and the intrinsic properties that shape responses to RGC input.
Consistent with previous work, we found at least four morphologically distinct classes of superficial-layer SC neurons: wide-field (WF), narrow-field (NF), piriform (P), and horizontal (H) cells. The same classes of neurons can be distinguished unambiguously on the basis of intrinsic biophysical features including input resistance, resting potential, spike shape, and spike rate in response to current injection. Preliminary in vivo results further suggest that WF, NF, P, and H neurons respond preferentially to distinct features of visual stimuli. For example, while both WF and H cells have broad dendritic arbors large spatial receptive fields, WF cells prefer small and moving stimuli whereas H cells respond better to large stimuli. NF and P cells have comparably more restricted dendritic arbors and spatial receptive fields. While most SC cells

were weakly or non-selective for movement direction, the majority of strongly directionally selective (DS) cells were NF cells. We are in the process of recording responses to synaptic input from specific types of DS-RGCs in brain slices in order to determine (1) which SC cells receive DS input and (2) how intrinsic membrane properties and dendritic architecture shape responses to such input.

Title: Three dimensional topography and projection lines within the mouse dorsal lateral geniculate nucleus (dLGN)

Authors: M. N. LEIWE[1], A. S. LOWE[1], S. J. EGLEN[2], *I. D. THOMPSON[1]

Abstract: The basic organisation of connections within the mammalian visual system is a series of ordered point to point maps that replicates the visual world. However, such topographical representation in central targets is complicated by the fact that the retina samples visual space through multiple retinal ganglion cell (RGC) channels. How does parallel processing integrate into a unified topographic representation? Classically, for the retino-geniculo-cortical pathway, this is defined by the ‘projection line’: the column of geniculate neurons projecting to a given point in primary visual cortex that sub-sample different RGC inputs. These lines have been best defined in primates and carnivores: along a projection line, the location in visual space is constant but the functional inputs vary. The mouse is an increasingly important model organism for understanding the emergence and organisation of retino-geniculo-cortical circuitry but little is known about the topological organisation within the dLGN. Unlike cortex or colliculus, it is not obvious that the dLGN is reducable to a two-dimensional sheet and linear projection paths.
Our classic approach to the ‘projection line’ is to inject retrograde tracers (<10 nl latex microbeads, LumaFluor) into the V1 of anaesthetised mice. Subsequently, we analysed the foci

of labelled cells in serial coronal sections of the dLGN. However, in order to understand the topology of projection paths in mouse dLGN, we have reconstructed the 3D shape of the dLGN by aligning the sections to a MRI template. This was achieved through manual alignment to the template, followed by fast free-form deformation to correct for histological distortions. This has allowed us to interpret the 3D distribution of labelled neurons within the standard dLGN space. For our range of cortical injections, we find that both the number and regional spread of labelled cells within dLGN do not correlate with the injection site volume. Our new 3D analyses allow us to define the co-ordinates of geniculo-cortical projection paths, and determine which parameters change with injection site location. Furthermore, using the same standard dLGN space allows us to examine information regarding the topography of the geniculo-cortical mapping by pooling data across animals. For instance, we can compare virtual pairs of injections to gain insight into the precision of the geniculo-cortical projection, which can then be verified experimentally. These findings not only describe the 3D topology of the retinotopic representation within the mouse dLGN but also have implications for investigating the functional heterogeneity of thalamic inputs into V1.

Title: Brain state and direction-selective cells in the dorsal lateral geniculate nucleus of awake rabbit.

Authors: *X. HEI[1], C. R. STOELZEL[1], J. ZHUANG[1], Y. BERESHPOLOVA[1], J. HUFF[1], J.-M. ALONSO[2,1], H. A. SWADLOW[1,2]

Abstract: Awake animals often shift between alert and non-alert states and the shift is correlated with profound changes in the behavior of the dorsal lateral geniculate nucleus (LGNd) concentric cells, such that, in the alert state, these cells have higher spontaneous activity, lower burst rates and stronger visual responses (Bereshpolova et al., 2011; Cano et al, 2006). The alert state is defined by the presence of hippocampal theta activity and cortical desynchronization; the non-

alert state is defined by high voltage irregular hippocampal activity and slow wave cortical activity. While the effects of state on concentric neurons have been well studied, direction-selective (DS) neurons make up a small but significant proportion (6.5-13.5%) of LGNd neurons in rabbit (Levick and Oyster, 1969; Swadlow and Weyand, 1985), and the effects of brain state on these cells are not known. Here we examine the receptive field properties of DS cells in rabbit LGNd in alert and non-alert states. We found that: 1) the distribution of preferred direction for ON-OFF DS cells fall into four groups, which is similar to that of ON-OFF retina DS ganglion cells (Oyster and Barlow, 1967); 2) Similarly to what we have shown for concentric cells, the spontaneous firing rate is higher in alert than non-alert states (13.7 spike/s vs. 7.8 spike/s, ~43% of reduction, p<0.01, n=7), while the burst rate is lower in the alert state (0.06 burst/s vs. 1.9 burst/s, p<0.001; n=6); 3) When compared to the non-alert state, the mean response rate in the preferred direction is significantly higher in the alert state (alert: 65.6 spike/s; non-alert: 51.6 spike/s; p<0.05, n=6). 4) In both states, the mean firing rate in the null direction is lower than the spontaneous firing rate (alert: p<0.01; non-alert: p<0.05; n=5). However, the rate reduction in the null direction is greater in alert state (mean rate=1.7 spikes/s) than in non-alert state (mean rate=3.7 spikes/s, p<0.05, n=6), and the directional selectivity index (DSI) is significantly larger in the alert state (0.95 vs. 0.87; p<0.01, n=5; DSI = (Pref - Null) / (Pref + Null); 5) There is no significant difference in directional tuning in these two states (half width at half height, alert: mean=52.5 degree; non-alert: mean=55.9 degree; p=0.51, n=6). These results show that the distribution of preferred direction is faithfully transmitted from retina to LGNd and the state effect on spontaneous firing and bursting is similar in rabbit LGNd DS cells and concentric cells. Although there is no effect of state on the directional tuning of these ON-OFF DS cells, the signal to noise ratio along the preferred-null axis is increased from non-alert to alert state.

Title: Very long lasting changes in the lateral geniculate nucleus after prolonged visual stimulation

Authors: *J. HUFF[1], C. R. STOELZEL[1], Y. BERESHPOLOVA[1], J. ZHUANG[1], X. HEI[1], J.-M. ALONSO[2,1], H. A. SWADLOW[1,2]

Abstract: The visual system adapts to prolonged intense visual stimulation at multiple levels, and psychophysical experiments, as well as those in retina and other central visual structures have examined such adaptations. Most single neuron studies have revealed adaptation effects that last from tens of milliseconds to a few minutes, while some psychophysical experiments have examined effects lasting tens of minutes. Here, we describe a novel, very long lasting adaption in the dorsal lateral geniculate nucleus (LGNd) of awake rabbits that persists for > one hour. We recorded single unit activity from concentric neurons in LGNd in awake rabbits. After characterizing the receptive field of the neuron with sparse noise stimulation, we recorded the spontaneous firing rates in the presence of a gray monitor screen. Initially, we studied only sustained LGNd cells, with a flickering high-contrast stimulus (1 sec on, 1 sec off) over the receptive field center for 10 - 30 minutes. This generated a sustained, high-frequency response to either the on or off phase of the stimulation. Following this prolonged stimulation regimen, all cells (n = 4) showed a severe reduction in spontaneous activity for as long as we studied these cells (periods of up to 50 minutes after stimulus, where recovery was still < 50%). All measures were taken in the alert state (Stoelzel et al. 2009). We then studied this phenomenon using less intense and less prolonged visual stimulation. One protocol was to use a drifting, high contrast grating for 10 minutes, after which we recorded the activity to the diffusely illuminated screen again. All trials resulted in a very long lasting pronounced reduction in firing rate (mean response 5-10 minutes after stimulation = 29.6% of the baseline activity, $p < 0.005$, n =4; mean response 70-75 minutes after stimulation = 47.6% of the baseline activity, $p < 0.005$, n=4), with one case not reaching 50% recovery in over two hours. A number of mechanisms could result in such a prolonged reduction in spontaneous firing. For example, such intense stimulation could cause a membrane hyperpolarization through various mechanisms. We propose that this is the case, because we measured a pronounced increase in “bursting” of the LGNd neuron throughout the periods of reduced spontaneous firing. These phenomena and their effects on visual responsiveness are currently under investigation.

Title: Abnormal visual system development in human albinism: A comparison of the optic chiasm and lateral geniculate nucleus using high resolution MRI

Authors: *L. MCKETTON, K. A. SCHNEIDER
Biol., York Univ., Toronto, ON, Canada

Abstract: *Introduction*
Albinism has been characterized as a genetic condition of hypopigmentation caused by melanocyte or melanin depletion due to an abnormality in melanin pigment synthesis. The lack of melanin severely impacts the development of the eye and visual system, including a variety of ophthalmic deficits such as reduced visual acuity and an abnormal decussation pattern of the optic chiasm. Our objective was to measure the extent of abnormal chiasmatic crossing in an albino population and examine the structure of the lateral geniculate nucleus (LGN).
Methods
Participants were scanned using a Siemens Trio 3T MRI scanner and 32-channel head coil in York University's Neuroimaging Laboratory. Anatomical regions of interest (ROIs) were created for the LGN by manually tracing 1 h of registered and averaged proton density weighted images and for the optic nerve and chiasm, from registered and averaged T1 weighted images. All masks were registered to DTI space for probabilistic tractography to visualize and quantify tracts coming from each optic nerve to each LGN as well as the inputs to different LGN layers. A whole-brain DTI scan was acquired with 64 diffusion directions, 8:05 minutes in acquisition time, field of view 192 mm, 56 2mm thick slices, TR = 6900 ms, TE = 86 ms and a 128 x 128 matrix. A second diffusion-weighted scan was acquired for diffusion spectrum imaging (DSI), which can resolve crossing fibers. This scan covered the eyes, optic nerves, optic chiasm, optic tracts and the LGN, using 256 diffusion directions, 10.57 minutes in acquisition time, 20 2mm thick slices, TR = 2500 ms, and TE = 86 ms.
Results
Using high-resolution imaging, we were able to reliably identify portions of each LGN innervated by either the left or right optic nerve. The LGN of albinos were significantly smaller than those of controls. We were able to measure the fraction of crossed and uncrossed fibers through the optic chiasm in the two populations using DTI and DSI.
Conclusions
We have demonstrated that it is possible to visualize and quantify differences in the visual system of subjects with albinism compared to controls using high resolution MRI.

Title: Functional mapping of the magnocellular and parvocellular subdivisions of human LGN

Authors: *R. N. DENISON[1], A. VU[1,3], D. A. FEINBERG[1,3], E. YACOUB[4], M. A. SILVER[1,2]
[1]Helen Wills Neurosci. Inst., [2]Sch. of Optometry, Univ. of California, Berkeley, Berkeley, CA; [3]Advanced MRI Technologies, Sebastopol, CA; [4]Dept. of Radiology, Ctr. for Magnetic Resonance Res., Univ. of Minnesota Med. Ctr., Minneapolis, MN

Abstract: Parallel processing in the visual system is well established in the lateral geniculate nucleus (LGN) of the thalamus, which has distinct anatomical subdivisions with complementary functional response properties. In particular, the magnocellular (M) subdivision of the LGN is selective for high temporal frequencies and low spatial frequencies, while the parvocellular (P) subdivision is selective for low temporal frequencies, high spatial frequencies, and color. However, the subdivisions of the LGN have rarely been studied in humans. Research has been limited by the difficulty of measuring neural responses from LGN subdivisions due to their small size and their location deep in the brain. We used high-resolution fMRI at field strengths of 3T and 7T, combined with presentation of visual stimuli designed to differentially activate M and P neurons, to functionally localize the M and P subdivisions in humans. At both 3T and 7T, we found a robust spatial gradient of BOLD responses to M-type and P-type stimuli across the LGN consistent with the known anatomical organization of M and P LGN layers. In addition, we found that the functional SNR in the LGN was significantly higher at 7T, thereby allowing for more reliable measurements or, alternatively, higher spatial resolution for equivalent SNR. This demonstrates the advantage of higher field strengths for studying functional properties of subcortical structures. The ability to reliably localize the M and P subdivisions of the LGN in humans will facilitate investigations of the roles of these specialized early visual pathways in human visual perception, attention, and cognition.

Title: Assessment of binocular interaction in the primate LGN.

Authors: *B. LANKOW, W. M. USREY
UC Davis, DAVIS, CA

Abstract: A central hypothesis regarding the eye- and stream-specificity of LGN lamination is that it facilitates the targeting of corticofugal fibers that participate in a feedback control circuit involved in the processing of visual information. Given the binocularity of many of the neurons that project from the visual cortex and from the thalamic reticular nucleus to the LGN, it is predicted that interocular modulation of LGN cell responses can be driven through these feedback pathways. This has been a contentious issue; while some studies have failed to find any reliable interocular influences in the LGN, other studies have suggested that it may be possible to modulate LGN responses with dichoptical stimulation paradigms. Several factors may drive these inconsistencies. On the one hand, because the activity of corticogeniculate neurons is strongly influenced by anesthesia and corticogeniculate synapses display rate-dependent facilitation, experiments testing feedback modulation need to be carried out in the alert animal. On the other hand, the small influence expected from non-dominant eye modulation may be difficult to assess reliably with traditional tuning measurements in the alert animal, where data can be noisy due to eye movements and other factors. We feel that this question of feedback and interocular modulation is important enough to warrant careful, focused testing. We are therefore conducting a series of experiments using a sensitive dichoptic reverse-correlation procedure to test interocular modulation of the response properties of LGN neurons in the individual layers of the LGN in the alert macaque monkey. Using reverse-correlation techniques, we have made measurements of luminance, disparity, chromaticity, and perceptual influences of non-dominant eye stimulation on the impulse response functions of individual LGN neurons. Preliminary results from these experiments suggest a negligible influence of binocular modulation in the visual processing of LGN cells in all layers of the LGN. These results indicate that binocular

factors in visual processing are implemented no earlier than layer 4c of the primary visual cortex.

Title: Retinal KCC2 and NKCC1 effects on direction selective ON and OFF responses in the rat's nucleus of the optic tract

Authors: *C. DISTLER[1], K. SPOIDA[2], A.-K. TRAMPE[2], K.-P. HOFFMANN[3]
[2]Zoology and Neurobio., [3]Animal Physiol., [1]Ruhr Univ. Bochum, D-44780 Bochum, Germany

Abstract: In the present study we investigated in vivo the effects of pharmacological manipulation of retinal processing on the response properties of direction selective retinal slip cells in the rat's nucleus of the optic tract and dorsal terminal nucleus (NOT-DTN), the key visuomotor interface in the pathway underlying the optokinetic reflex. Employing a moving visual stimulus consisting of either a large dark or light edge we could differentiate direction selective ON and OFF responses in retinal slip cells.
To disclose the origin of the retinal slip cells' unexpected OFF response we selectively blocked the retinal ON channels and inactivated the visual cortex by cooling. Cortical cooling had no effect on the direction selectivity of the ON or the OFF response in NOT-DTN retinal slip cells. Blockade of the retinal ON channel with APB led to a loss of the ON and, to a lesser degree, of the OFF response and a reduction in direction selectivity. Subsequent blocking of GABA receptors in the retina with picrotoxin unmasked a vigorous albeit direction unselective OFF response in retinal slip cells of the NOT-DTN. Disturbing the retinal chloride homeostasis by intraocular injections of bumetanide or furosemide led to a loss of direction selectivity in both the NOT-DTN's ON and the OFF response due to a reduced response in the neuron's preferred direction under bumetanide as well as under furosemide and a slightly increased response in the null direction under bumetanide.
Our results indicate that the direction specificity of retinal slip cells in the NOT-DTN of the rat strongly depends on intraretinal chloride homeostasis which was shown to be important for retinal direction selectivity (Gavrikov et al., PNAS 100: 16047-16052, 2003;Gavrikov et al.,

PNAS 103: 18793-18798, 2006). On top of the well established input from ON center direction selective ganglion cells we could demonstrate an equally effective input from the retinal OFF system to the NOT-DTN.

Title: The anatomy of the centrifugal visual system and its influence on eye development.

Authors: *C. M. DILLINGHAM, J. A. GUGGENHEIM, J. T. ERICHSEN
Visual Neurosci. and Mol. Biol., Cardiff Univ., Cardiff, United Kingdom

Abstract: Purpose: We investigated the role of the centrifugal visual system (CVS), which projects from the brain to the retina, in emmetropization
Methods: In Experiment 1, electrolytic lesions of the isthmo-optic nucleus/tract (ION/t) or sham-surgeries were performed on 4/5-day-old chicks (n=54; Shaver-Black) to disrupt centrifugal efferents to the retina. Ocular phenotyping (A-scan ultrasonography, keratometry and retinoscopy) was performed 7 and 21 days post-surgery. In Experiment 2, lesions were performed as above. Then, following surgery, either a plus (n=21), a minus (n=20) or a plano lens (n=14) was fitted in front of the treated (contralateral) eye for a period of 7d, followed by a recovery period of 14d. Ocular phenotyping was performed 7d, 14d and 21d post-surgery. At the completion of both experiments, an intra-vitreal injection of WGA was made to the eye contralateral to the lesion, followed 48hr later by perfusion fixation, sectioning, anti-WGA immunohistochemistry and stereological analysis. Counts of remaining (i.e. labeled) ION/t centrifugal neurons were compared to sham controls to determine lesion success. Subjects were split into quartiles based upon lesion success (Q1-Q4) with Q1 representing the lowest and Q4 the highest lesion success.
Results: An overall lesion effect on refractive state asymmetry was found 7 days post-surgery ($F(3,50) = 7.104$, $p<0.001$): Treated eyes of subjects in the highest percentage lesion success quartile (Q4) showed a mean hyperopic shift, relative to control eyes (T-C) at 7d post-surgery of 2.31 D ± 2.46, $p=0.568$). After 21d post-surgery, the initially observed anisometropia in the highest lesion success quartile was no longer apparent (Q4 anisometropia −0.17 D ± 0.48,

p=0.214). In response to myopic and hyperopic defocus, all lesion groups showed comparable refractive and axial compensation (p=0.534 and 0.213, respectively). While all groups showed a similar recovery capability from lens-removal induced defocus, Q4 subjects treated with plus lenses showed a minor but significant overshoot in correction from induced hyperopia relative to both sham operated controls and fellow control eyes (both $p<0.05$). Pathway tracing experiments reveal brainstem interhemispheric connections within the CVS that may play a role in normal eye development.
Conclusions: Unilateral disruption of centrifugal efferents to the retina of the contralateral eye appears to result in a moderate axial hyperopia that is subsequently reversed in a developmentally induced recovery period. However, compensation to lens induced defocus and subsequent recovery are largely unaffected.

Title: Thalamocortical conduction latencies and latencies of visually evoked responses in marmoset lateral geniculate nucleus.

Authors: S. K. CHEONG[1,2], A. N. J. PIETERSEN[1,2], B. DREHER[3], S. G. SOLOMON[3,2], *P. R. MARTIN[1,2]
[1]Save Sight Inst., Univ. of Sydney, Sydney, Australia; [2]ARC Ctr. of Excellence in Vision Sci., [3]Sch. of Med. Sci., The Univ. of Sydney, Sydney, Australia

Abstract: ***Purpose:*** To study connectivity of the “Blue-ON” koniocellular (K) visual pathway from the lateral geniculate nucleus (LGN) to the primary visual cortex (V1). We also asked whether the conduction latencies of LGN cells significantly contribute to the latencies of visually evoked responses in the parallel visual pathways. ***Methods:*** Single unit, extracellular recordings were made in the LGN of sufentanil-anaesthetized marmosets (*Callithrix jacchus*, n = 4). Electrical current (0-5 mA, 50 μs) was injected into V1 using bipolar electrodes. Antidromic activation of LGN cells was assessed using the collision test and conduction latencies were measured. Visual response latencies were measured in LGN using a 70% Michelson contrast, spatially uniform stimulus filling the receptive field. Receptive fields were characterized using

drifting sinusoidal achromatic and short wavelength sensitive (S)-cone isolating gratings. ***Results:*** 23 LGN cells were activated antidromically from V1: 4 Blue-ON K cells; 1 "non-Blue" ON K cell; 6 parvocellular (P); and 12 magnocellular (M) cells. The P cells had latencies of 1.89 ± 0.16 ms (mean ± SD); M cells 1.17 ± 0.23 ms; and Blue-ON K cells 1.80 ± 0.27 ms. The ON K cell had a latency of 2.39 ms. Thalamocortical latencies were on average 3 ± 1% (mean ± SD) of the visual response latency and were positively correlated with visual response latencies (r^2 = 0.68, p = 0.002). Orthodromic activation was observed in three M cells with latency 2.04 ± 1.53 ms (mean ± SD). ***Conclusion:*** Blue-ON K LGN cells make direct connections to V1, substantiating the hypothesis that the K pathway carries signals serving the blue-yellow axis of color vision. The latency of this connection is similar to that of P cells. The conduction latency of thalamocortical fibers contributes very little to the overall latency of visually-evoked signals arriving at V1.

Title: The distribution of synapsin I & II in the visual thalamus of bush babies

Authors: J. P. PATEL[1], M. KOO[1], K. LI[2], J. A. MAVITY-HUDSON[3], R. T. MARION[4,5], G. PURUSHOTHAMAN[3], D. YAMPOLSKY[3], Y. JIANG[2], *V. A. CASAGRANDE[3,2,6]

Abstract: As part of larger project designed to understand the organization of primate visual thalamus, we compared the distribution of two proteins, synapsin I and synapsin II to the location of visuotopic maps and known inputs to the pulvinar and lateral geniculate nucleus

(LGN) of the prosimian primate, Otolemur garnettii. Synapsin I and II are proteins that tether a reserve pool of synaptic vesicles and have been linked to synaptic plasticity in the mouse visual system (Kielland et al., 2006). Additionally, these proteins have been shown to identify tecto-pulvinar terminals in tree shrew as well as cortico-thalamic but not retino-fugal pathways in the both tree shrew and rat (Wei et al.,2011). We used standard immunocytochemical methods to identify these proteins which also were compared to the known distributions of other markers of pulvinar subdivisions and LGN layers in bushbaby such as vesicular glutamate transporter 2, VGluT2 and cytochrome oxidase (CO). Synapsin I and II showed an even above background distribution in pulvinar that did not correlate with pulvinar subdivisions defined by visuotopic mapping, tectal connections or other protein markers but could reflect the broad input that all subdivisions of pulvinar receive from cortex. In contrast, in the LGN synapsin I and II were most dense in koniocellular layer 4 (K4) and least dense in the parvocellular (P) layers. It is noteworthy that LGN layer K4 receives a dense input from the superior colliculus, yet the colliculus also projects to the other K LGN layers which were clearly defined by VGluT2 immunostaining but did not stand out as more heavily labeled than the magnocellular (M) LGN layers with either synapsin; VGluT2 densely and precisely outlined all the K LGN layers. In fact, VGluT2which has been shown to exist in retinogeniculate terminals, appeared to be particularly dense in the terminals within all the LGN K layers and was only weakly evident in the terminals within the P LGN layers and moderately dense in the LGN M layers. VGluT2 also was evident in dense terminal patches in lateral and inferior pulvinar which co-localized to some extent with CO patches in these subdivisions of pulvinar. That could indicate the location of collicular inputs to these subdivisions of pulvinar (Baldwin et al.,2011). These results suggest that the synapsin proteins do not localize specifically in zones of primate pulvinar that receive collicular input as might be the case for VGluT2. Instead, the distribution of synapsins appeared to correlate most closely with the distribution of cortical input which innervates all subdivisions of primate pulvinar.

Title: Molecular specificity of monkey retinal ganglion cells during development

Authors: *K. D. MURRAY[1], D. VAN DER LIST[2], W. MARTIN USREY[3]
[1]Psychiatry & Behavioral Sci. and Ctr. for Neurosci., [2]Neurobiology, Physiol. & Behavior and Ctr. for Neurosci., [3]Neurobiology, Physiol. & Behavior and Ctr. for Neurosci., Univ. California Davis, Davis, CA

Abstract: Visual information travels from the eye to the dorsal lateral geniculate nucleus (dLGN) of the thalamus via parallel pathways that originate from distinct classes of retinal ganglion cells (RGCs) distinguished by unique receptive-field properties, cytoarchitecture, and axonal termination patterns. Despite the profound influence of these parallel pathways on subsequent visual processing, we know relatively little about the mechanisms that guide the functional maturation of RGC diversity. To address this issue, we investigated the molecular maturation of parasol and midget RGCs in the macaque monkey; these cell types target the magnocellular and parvocellular layers of the dLGN, respectively. Using a discovery-based approach we identified sets of genes unique to parasol and midget RGCs that might underlie their functional maturation. Parasol and midget RGCs were individually isolated from embryonic (GD140), early postnatal (10 week old) and adult monkey retinas by laser-capture microscopy, and total RNA was processed for Affymetrix microarray analysis. On average 28±2% of arrayed probe sets were positively hybridized by monkey RGC RNA. A probe level analysis was performed on robust multichip-averaged data using GeneSpring GX software (v. 12.0) and genes that satisfied a 2-fold expression difference (based on age or cell-type comparisons) and a p value of ≤ 0.05 (2-way ANOVA) were identified. Overall, significantly more genes were downregulated ($\sim$800) than upregulated ($\sim$400) during development. A surprising number of genes had transiently increased expression at 10 weeks of age ($\sim$600) compared to embryonic or adult RGCs. When we compared cell type, a greater number of genes were differentially expressed between parasol and midget RGCs in adult retina ($\sim$150) compared to early postnatal ($\sim$60) and embryonic ($\sim$80) retinas, suggesting a developmental maturation of cell-type specificity. Analysis of the interrelatedness of differentially expressed genes using Ingenuity Pathway Analysis software suggested molecules associated with intercellular signaling and cellular organization and development were among the top differentiators of RGC identity. Subsequent cellular confirmation of differential expression will identify markers useful for delineating the functional maturation of monkey retinal circuitry.

Title: Firing-rate models for the retina-LGN connection derived from experiments

Authors: T. HEIBERG[1], B. KRIENER[1], T. TETZLAFF[2], A. CASTI[3], G. T. EINEVOLL[1], *H. E. PLESSER[1]

Abstract: Firing-rate models provide a practical tool for studying the signal processing in the early visual system (Dayan & Abbott, 2001). Nordlie et al (2010) have recently shown that rate-based models can capture the response properties of model neurons with strong synapses, as commonly found in retinogeniculate connections. Here we obtain firing-rate models of lateral geniculate nucleus (LGN) relay cells based on a neuron model with conductance-based synapses and after-hyperpolarizing currents fitted to cat relay cells (Casti et al, 2008) and on a spike-response model fitted to macaque relay cells (Carandini et al, 2007).
Our approach is based on Nordlie et al (2010): Input spike trains were modeled as inhomogeneous Poisson point processes with sinusoidally modulated rate. Average rates, modulation amplitudes, and phases of the period-averaged spike responses were measured for each of the data-fitted neurons and a broad range of stimulus parameters. The resulting responses are well described by a linear first-order low-pass filter. Combining this filter with the nonlinear response characteristic for stationary inputs, we constructed a linear-nonlinear firing-rate model, which accurately predicted the population response for a variety of non-sinusoidal test stimuli.
Spike trains from the retina have been shown to be more regular than a Poisson process (Troy & Robson, 1992). Thus, we further investigated the effect of presynaptic spike-train regularity on the models. We found that more regular spike input can lead to rectification of low-rate and linearization of high-rate input. Overall, the rate models perform well for both regular (high-order Gamma) and irregular (Poisson) input.
Our results indicate that firing-rate models with time constants as low as a few milliseconds can be used to model signal processing at the retina-LGN connection.

Title: Functional coupling between neuronal Fc-gamma receptor and the transient receptor potential canonical 3 (TRPC3) channel in IgG immune complex-induced activation of dorsal root ganglion neurons

Authors: L. QU[1], Y. LI[2], X. PAN[2], P. ZHANG[1], R. H. LAMOTTE[1], *C. MA[3]
[1]Dept. of Anesthesiol., [2]Dept. of Genet., Yale Univ. Sch. of Med., New Haven, CT; [3]Dept. of Anatomy, Histology and Embryology, Inst. of Basic Med. Sciences, Chinese Acad. of Med. Sciences, Sch., Beijing, China

Abstract: Pain may accompany antigen-specific immune diseases but the underlying mechanisms remain obscure. One common feature of these diseases is the elevated serum/tissue level of IgG immune complex (IgG-IC). We previously demonstrated that IgG-IC directly excited a subset of dorsal root ganglion (DRG) neurons in rats through neuronal Fc-gamma receptor I (FcγRI) and may induce pain. However, the signaling pathways and transduction

channels activated downstream of IgG-IC are largely unknown. In the rat DRG neurons, recorded with whole-cell patch-clamp electrophysiology, IgG-IC induced a non-selective cation current (I_{IC}) carried by Ca^{2+} and Na^{+}, and regulated/sensitized by intracellular Ca^{2+}. Single-cell RT-PCR revealed that the mRNA of transient receptor potential canonical 3 (TRPC3) was always coexpressed with FcγRI mRNA in the same DRG neuron. Moreover, the I_{IC} was inhibited by ruthenium red (a general TRP channel blocker), BTP2 (a general TRPC channel inhibitor) or pyrazole-3 (a selective TRPC3 blocker). Specific knockdown of TRPC3 using small interfering RNA attenuated IgG-IC-induced Ca^{2+} response and the I_{IC}. Additionally, the I_{IC} was blocked by tyrosine kinase Syk inhibitor OXSI-2, phospholipase C (PLC) inhibitor neomycin, or the IP_3 receptor antagonist 2-aminoethyldiphenylborinate or heparin, but not affected by DAG analog OAG. These results indicated that TRPC3 functionally couples to neuronal FcγRI through the Syk-PLC-IP_3 pathway, and acts as a key downstream transduction channel mediating the depolarizing effects of IgG-IC on DRG neurons. Our findings may provide new therapeutic strategies for the pain related to antigen-specific immune diseases.

Title: Contribution of TRPC channels to calcium regulation in DRG sensory neurons and nociception

Authors: H. ALKHANI[1], A. R. ASE[1], R. GRANT[2], D. O'DONNELL[2], *P. A. SEGUELA[1]
[1]Dept Neurol & Neurosurg., Montreal Neurol. Inst., Montreal, QC, Canada; [2]AstraZeneca R&D Montreal, Ville Saint-Laurent, QC, Canada

Abstract: Pain is an unpleasant sensation experienced following injury, inflammation or ischemia. Pathologically abnormal intracellular calcium levels in DRG neurons are linked to

hyperexcitability and chronic pain. Tight regulation of cytosolic calcium levels is key to maintaining calcium homeostasis and SOCE (store-operated calcium entry) has been implicated as a major control mechanism of intracellular calcium levels. The TRPCs (transient receptor potential, canonical) are tetrameric calcium-permeable cation channels with a documented role in store- and receptor-operated responses linked to phospholipase C. TRPCs have been shown to integrate intracellular and extracellular stimuli, including algesic mediators ATP and glutamate, into membrane potential changes and calcium entry, therefore they could play a critical role in peripheral nociception. Our in situ hybridization data on the cellular distribution of the entire 7-member TRPC gene family indicated that TRPC1 and TRPC3 mRNAs are strongly expressed in adult rat DRG sensory neurons. Using calcium imaging, pharmacology as well as expression of STIM1 and TRPC dominant-negative mutant subunits, we gathered evidence for a significant involvement of both TRPC1 and TRPC3 in calcium responses as store- and GqPCR-operated channels in recombinant and native preparations. We are currently investigating the contribution of TRPC1 and TRPC3 function to DRG neuron excitability and calcium-dependent pathways in physiological conditions and chronic pain states.

Title: A genetically tractable model of noxious cold detection in *Drosophila* larvae

Authors: *H. N. TURNER, M. J. GALKO
Biochem. and Mol. Biol., MD Anderson Cancer Ctr., Houston, TX

Abstract: An organism’s comfort and ultimately its survival depends on the ability to detect and avoid noxious thermal stimuli thus preventing tissue damage. In some disease states, patients can experience painful and maladaptive perception of innocuous cold and heat or an inability to perceive noxious cold or heat. Our current understanding of the basic biology of noxious cold perception is gravely minimal. Our goal is to determine the genetic basis for noxious cold perception using the genetically tractable Drosophila model. We have developed a novel “cold probe” that allows focal application of a defined noxious cold stimulus (3-15 ºC), and found that

Drosophila larvae produce a mutually exclusive set of primary reactive behaviors, distinct from the previously described aversive “corkscrew” behavior seen in response to a high temperature probe (1). These behaviors include a tail raise (TR) of approximately 45-90°, a combined head and tail raise (HT) of 45-90°, and a full-body scrunching (SC) behavior, likely to be similar to the “accordion-like” behavior reported previously (2). Below 12º C, the resulting behaviors occur in approximately 60% of larvae, and are consistent and reproducible. We have attained 13 transient receptor potential (TRP) whole animal mutants and are testing these larvae with the cold probe to determine the possible contributions of each of the TRP channels on producing the cold-specific behaviors. To date we have found that two mutants previously reported to affect perception of noxious heat, pyrexia and dTRPA1, both show an increase in HT behavior and a decrease in SC behavior. Meanwhile, brivido mutants recently reported to affect ambient cold preference, have exactly the opposite phenotype- decreasing HT behavior and increasing SC behavior. We will report on the behavioral phenotypes of these and other TRP mutants. Taken together, our unique tool and assay and the other sophisticated genetic approaches available in the fly should allow us to uncover the conserved molecular/genetic basis of noxious cold perception. Title: Translational profiling approach for the molecular characterization of trpm8 sensory neurons

Authors: *D. MCCOY, D. MCKEMY
USC, Los Angeles, CA

Abstract: The sensory nervous system is responsible for the detection of a wide variety of environmental cues. One sensory pathway in which biological players have been identified is that of temperature sensation. A number of Transient Receptor Potential (TRP) ion channels

have been found to play integral roles in the perception of temperature in that they are thermally-gated, leading to nerve firing upon activation. The channel TRPM8 detects both noxious and innocuous cold and is the molecular basis for the cooling associated with menthol. It has been directly implicated in the cold allodynia associated with inflammation, nerve injury, and certain chemotherapeutic drug treatments. TRPM8 knockout studies have shown that the channel is necessary for the development of many of these injury-induced cold hypersensitivities making it likely that cold-sensitive, TRPM8 positive neurons change in response to injury. Recent work has identified candidate molecules involved in the sensitization to cold stimuli. For example, specific potassium channel Kv1 inhibitors have been shown to increase cold sensitive neuron temperature thresholds in vitro. Additionally, recent work in our lab has shown that Phospholipase C (PLC)-mediated depletion of the phospholipid PIP2 results in reduced cold-induced TRPM8 currents. Thus, a gene expression analysis of cold-sensitive, TRPM8-expressing neurons in models of these hypersensitive states would help in the understanding of the molecular basis for thermal hypersensitivity and could reveal new therapeutic targets for these conditions. Typical gene expression profiling approaches use fluorescence-activated cell sorting (FACS) to collect a specific cell subtype to be profiled. However, TRPM8 is expressed in a small subset of neurons and, due to the inefficiencies in attaining ample amounts of mRNA using FACS, an alternative approach is needed. Here we describe the development of a mouse transgenic model which can circumvent these pitfalls using the (TRAP) Translating Ribosome Affinity Purification technique which employs the use of an eGFP labeled ribosomal protein L10a (eGFP-L10a) as a means to pull down cell-specific translating mRNA sequences when genetically targeted to TRPM8-expressing neurons. Additionally, we have further diversified the use of this technique by developing a CRE-dependent construct in which eGFP-L10a and mCherry-L10a can be selectively targeted. This technique allows for transcripts from two different populations to be simultaneously isolated from the same tissue source and will be particularly beneficial in the characterization of cell types in which distinct subpopulations have been identified.

Title: Cold receptor activity in the tongue of TRPM8 and TRPA1-deficient mice

Authors: *B. L. DENLINGER, F. VIANA, C. BELMONTE
Inst. de Neurociencias, San Juan de Alicante, Spain

Abstract: The tongue is richly innervated by cold-sensitive nerve afferents. The molecular basis of cold transduction in sensory fibers is not fully understood; TRP channels and leak K+ channels are thought to play important roles. We developed an 'in vitro' preparation of the superfused mouse tongue to record impulse activity in single sensory fibers of the lingual nerve in wild-type, TRPM8 (Dhaka et al., 2007), TRPA1 (Kwan et al., 2006) and TRPM8/TRPA1 null mice and analyzed the effect of controlled thermal stimuli on this activity. Sustained nerve impulse discharges were evoked in a fraction of sensory fibers when temperature of the perfusing solution was decreased from a basal temperature of 34-35º down to 10ºC. Based on their thermal threshold, cold-sensitive fibers were subdivided into low (greater-than or equal to 26ºC, LT) and high threshold (< 26ºC, HT) fibers. Deletion of TRPM8 did not completely abrogate the population of cold-sensitive fibers with those still responding to cold exhibiting thresholds in the low and high ranges. The vast majority of cold-sensitive fibers in TRPA1 -/- were LT fibers, supporting the contention that cold transduction in the population of HT fibers depends largely on TRPA1. In TRPM8/TRPA1 -/- mice, cold-sensitive fibers were still found, all being LT fibers. Chloroform (20 mM), an activator of thermosensitive TREK-1 potassium channels, attenuates or eliminates responses of these fibers to cold. Altogether, these results indicate that activation of lingual sensory fibers by cold depends on several transduction mechanisms. TRPM8 appears to be important but not unique for the detection of discrete temperature reductions. Other channels, presumably background potassium channels appear to be also involved, while TRPA1 seems to mediate transduction of more intense cooling.
We also explored the contribution of cold thermoreceptors in the oral mucosa to drinking preference and overall water intake in mice using an experimental cage in which the water temperature of two drinking bottles could be cooled and heated from a control temperature of 22ºC. After water deprivation during 24 hours, drinking time and volume were measured over a 1 hour period. Wild-type mice drastically preferred water at 22ºC over cooler water, while TRPM8 -/- mice had no preference and TRPM8/TRPA1 -/- mice even preferred the cooler water. TRPA1 -/-mice preference closely resembled that of the wild-type mice. All knockouts also spend a longer total time drinking at each temperature than wild-type mice. These data suggest that cold thermoreceptor signaling, in particular mediated by TRPM8 channels is an important cue in thirst and in preabsorptive signaling of satiety.

Title: The role of TRPM8 and TRPA1 in the cold responses of mice

Authors: *D. S. BRENNER, R. W. GEREAU, IV
Washington Univ. In St Louis, Saint Louis, MO

Abstract: Pain is an important clinical and societal issue, costing $99 billion in federal and state medical expenditures in 2008 alone. Despite this expense, recent studies have concluded that pain management must be improved in key patient populations including postoperative patients and cancer patients. Pain can be subdivided into different categories including mechanical, heat, and cold pain, which can have different mechanisms of transduction and transmission. Cold pain is particularly clinically relevant, as broad populations including multiple sclerosis, chemotherapy, and stroke patients all experience types of cold hypersensitivity.
Work over the last decade has suggested that the Transient receptor potential (TRP) channels TRPM8 and TRPA1 may be physiologically sensitive to cold stimuli. Nevertheless, there is still some controversy over the role of TRPA1 in cold pain. This controversy is due, in part, to limitations in the behavioral assays currently available to measure cold responses in vivo. To complement the assays currently in use, we have applied our new assay of cold response threshold, the cold plantar assay, to further define the roles of TRPM8 and TRPA1 in acute, inflammatory, and neuropathic cold responses.

Title: Thermal sensitivity of voltage-gated Na^+ channels and A-type K^+ channels confers sensory discrimination between innocuous and noxious cold by primary afferent neurons

Authors: *J. GU[1], I. SARRIA[2], J. LING[2], R. IKEDA[2]
[1]Univ. Cincinnati Col. of Med., Cincinnati, ; [2]Univ. Cincinnati Col. of Med., Cincinnati, OH

Abstract: Both innocuous and noxious cold activate TRPM8, a principal cold transducer, raising a question how the two subtypes of sensory modalities are discriminated by the sensory system. Since TRPM8 is located on both tetrodotoxin-sensitive (TTXs) and tetrodotoxin-resistant (TTXr) Na^+ channel-expressing primary afferent neurons, we hypothesize that the sensory discrimination between innocuous and noxious cold is partially due to thermal sensitivity differences between TTXs channels and TTXr channels. To test this hypothesis, we investigated whether and how action potential firing properties in TTXs and TTXr neurons of rat dorsal root ganglions were differentially modified by cooling temperatures. We found that action potential firing in response to membrane depolarization was suppressed in TTXs neurons but maintained or facilitated in TTXr neurons at noxious cold temperatures. We showed that cooling temperatures strongly inhibited TTXs Na^+ channels and A-type K^+ currents (IA) but had fewer inhibitory effects on TTXr Na^+ channels, and that the thermal sensitivity of these voltage-gated ion channels determined action potential firing properties in both TTXs and TTXr neurons at cooling temperatures. Finally, we found that TRPM8-expressing TTXs neurons and TRPM8-expressing TTXr neurons fire action potentials at innocuous and noxious cold temperatures respectively, demonstrating sensory discrimination between innocuous and noxious cold by the two groups of cold-sensing neurons.

Title: Acute cold hypersensitivity characteristically induced by oxaliplatin is caused by enhanced responsiveness of TRPA1 in mice

Authors: *M. ZHAO, H. SHIRAKAWA, T. NAKAGAWA, S. KANEKO
DEPARTMENT OF MOLECULAR PHARMACOLOGY, Kyoto Univ., KYOTO, Japan

Abstract: Oxaliplatin, a platinum-based chemotherapeutic agent, causes peculiar acute peripheral neuropathy. Oxaliplatin-induced acute peripheral neuropathy appears in almost all patients rapidly after infusion and is triggered or exacerbated by cold, but the mechanisms are poorly understood. In this study, we investigated the involvements of thermosensitive transient receptor potential (TRP) channels, TRPA1, TRPM8 and TRPV1 in the oxaliplatin-induced acute hypersensitivity in mice. A single intraperitoneal administration of oxaliplatin (5 mg/kg) induced cold hypersensitivity within 2 hours, while mechanical hypersensitivity was not observed in the early phase. The oxaliplatin-induced acute cold hypersensitivity was inhibited by calcium (0.5 mmol/kg i.v.) or gabapentin (30 mg/kg, i.p.). Similar with oxaliplatin, a single intraperitoneal administration of oxalate (1.7 mg/kg), a metabolite of oxaliplatin, also induced cold hypersensitivity within 2 hours, while neither cisplatin (5 mg/kg) nor paclitaxel (6 mg/kg) induced mechanical or cold hypersensitivity 2 hours after oxaliplatin. These findings suggest that the rapid-onset cold hypersensitivity is representative of the acute peripheral neuropathy characteristic to oxaliplatin in mice. The oxaliplatin-induced acute cold hypersensitivity was abolished by a TRPA1 antagonist, HC-030031 (100 mg/kg) or TRPA1 deficiency. Furthermore, nocifensive behaviors induced by intraplantar injection of allyl-isothiocyanate (AITC; TRPA1 agonist) and menthol (TRPM8/TRPA1 agonist) were significantly enhanced 2 hours after oxaliplatin, while capsaicin (TRPV1 agonist)-induced nocifensive behaviors were not affected. Similarly, oxalate enhanced the AITC-induced nocifensive behaviors, while cisplatin and paclitaxel had no effects. When mouse cultured dorsal root ganglion (DRG) neurons were pretreated with oxaliplatin (100 μM) for 1, 2 or 4 hours, the number of AITC-sensitive neurons was increased, but neither that of menthol- nor capsaicin-sensitive neurons was changed. In HEK293 cells expressing recombinant human TRPA1, high dose oxaliplatin (1 mM) evoked a calcium response. Taken together, these results suggest that short treatment with oxaliplatin characteristically leads to the enhanced responsiveness of TRPA1, but not TRPM8 and TRPV1, on DRG neurons, which may contribute to the oxaliplatin-induced acute peripheral neuropathy.

Title: A high density of TRPM8 expressing sensory neurons in specialized structures of the head

Authors: *J. NEWSOM[1], J. L. HOLT[1], J. K. NEUBERT[2], R. CAUDLE[2], A. H. AHN[1]
[1]Col. of Med., [2]Col. of Dent., Univ. of Florida, Gainesville, FL

Abstract: Transient receptor potential melastatin 8 (TRPM8) receptor is expressed at high levels in the trigeminal ganglion, and is much more abundant there than in the dorsal root ganglia. Among the possible explanations for this are a higher number and density of cold-receptive nociceptors in the head than in other regions of the body. Alternatively, certain structures in the head that serve their own unique functions could differentially express a high density of TRPM8 expressing terminals, which would include the sensation of cold pain, such as in the eye, teeth, face, and oropharynx. In order to better appreciate the functional significance of high levels of TRPM8 in the trigeminal ganglia, we have characterized the expression of TRPM8 receptor terminals in the above terminal fields. Using a mutant mouse in which a GFP reporter has been mutated directly into the TRPM8 locus (Dhaka et al 2008), we determined the expression of GFP-expressing terminals in whole mount sections of the head. By the immunohistochemical detection of GFP, together with functional markers of primary afferent neurons, we have determined the localization and neurochemical identity of TRPM8-GFP expressing neurons in the head and compared them to other non-trigeminal terminal fields. The neurochemical identity of these neurons was determined in relation to the lectin IB4, a marker of non-peptidergic unmyelinated nociceptors, as well as CGRP, a marker of peptidergic nociceptors. We found only sparse innervation of the mucosa of the nasopharynx and turbinates, optic nerve, and the dura-meninges (as was reported previously by retrograde labeling of the dura). However, we found numerous and dense terminal arbors in the epithelium of the midline oropharynx and distal tongue, cornea, and conjunctiva. Accordingly, we found GFP-expressing axons of passage in the corresponding branches of the trigeminal nerve, such as the superior alveolar nerve, a branch of V2 that lies directly above the oropharynx, as well as the mandibular and lingual nerves, originating in the V3 branch of the trigeminal nerve. These findings will be of translational interest in understanding a number of pain behaviors and experiences related to cold pain and reactivity to cold such as dental pain, trigeminal neuralgia, migraine, and possibly the experience of “ice-cream headache.”

Title: Cold-activated trpm8 channels are activated by the volatile anaesthetic chloroform

Authors: A. PARRA, J. MANENSCHIJN, O. GONZÁLEZ, H. VARA, C. MORENILLA, C. BELMONTE, *F. VIANA
Inst. De Neurociencias UMH-CSIC, San Juan De Alicante, Spain

Abstract: TRPM8 is a member of the transient receptor potential family of non-selective cationic channels. TRPM8 is activated by cold temperature, cooling compounds and voltage. Recent studies have implicated TRPM8 in the pathophysiology of cold nociception and cold allodynia, leading to a strong interest in the search for novel modulators of TRPM8 activity. Here we describe the effects of chloroform (CLF), a volatile aneasthetic.
Using patch-clamp techniques, we studied CLF-induced responses in a HEK293 cell line stably expressing rat TRPM8. CLF activated whole-cell currents with a typical TRPM8 signature (strong outward rectification and near zero mV reversal). Using ratiometric fluorescence calcium imaging, we found that the effect of CLF was concentration-dependent and reversibly blocked by BCTC, a TRPM8 antagonist. CLF activated HEK293-cells transfected with the menthol-insensitive Y745H-TRPM8 mutant normally. We also investigated effects of CLF on cold-sensitive neurons from the dorsal root ganglia (DRG) of adult TRPA1-KO mice, and found that CLF activates these neurons, an effect which is reversibly blocked by BCTC. Similar effects were found in TRPM8-YFP(+) cold-sensitive DRG neurons driven by the TRPM8 promoter. Our results suggest that a low concentration of CLF is able to decrease

the threshold of TRPM8 by cold.
Finally, we recorded spontaneous Nerve
Terminal Impulse (NTI) activity from cold thermoreceptors innervating the mouse cornea *in vitro*. CLF augmented NTI
resting activity and increased mean frequency during sustained cooling pulses. The excitatory effects of CLF were reversibly blocked by BCTC and did not exist in TRPM8 -/- mice.
In brief, we show robust activation of
heterologously and natively expressed TRPM8 channels by CLF. The mechanism of activation is yet unexplained. However, the absence of the menthol binding site did not affect the effect of CLF on TRPM8, suggesting that this site is not critical for its activation by chloroform.

Title: Splice variants of trpm3 and their roles in sensory transduction

Authors: T. KIM[1], J. JUNG[1], D.-J. YANG[1], *Y. JANG[2], H. CHUN[1], H. KIM[1], J. OH[1], U. OH[1]
[2]Pharmacol., [1]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Transient receptorpotential melastatin 3 (TRPM3), a member of transient receptor potential channel superfamily, is a non-selective cationic channel with various splice variant forms. TRPM3 is now known to play a role in Ca^{2+}-induced insulin release from pancreatic beta cells or contraction of vascular smooth muscle. Recently, TRPM3 is also known to function as a thermo-sensor in sensory neurons. TRPM3 has many splice variants. However, roles of TRPM3 splice variants are largely unknown. Because TRPM3 is highly expressed in dorsal-root ganglion neurons, thus each splice variant may have different functions in sensory transduction. Thus, we sought to identify genes of splice variants of TRPM3 in sensory neurons and determine their

biophysical responses to various stimuli.
Six of TRPM3 splice variants were cloned based on sequence information of NCBI gene bank. All of six splice variants were expressed in mouse dorsal root ganglion neurons. Especially, TRPM3 *variant 2* (*v2*), *v3* and *v6* showed higher expression levels than *v4 and v5*. We then examined whether these splice variants have different responses to heat and pregnenolone sulfate (PS), an endogenous agonist of TRPM3. Although TRPM3 *Variant 1-5* showed similar current amplitudes (0.23±0.05 nA to 50 μM PS). TRPM3 *v6* showed significantly smaller currents to the PS. In contrast, all of TRPM3 splice variants were activated to heat with identical thresholds and current responses. These results show that splice variants of TRPM3 may have different roles as they have different sensitivities to endogenous stimuli.

Title: Keratinocyte stimulation is sufficient to trigger pain in mice

Authors: *M. CATERINA[1], T. SAKAMOTO[1], Z. PANG[1], A. D. GULER[2,3]
[1]Biol. Chem., Johns Hopkins Sch. Med., BALTIMORE, MD; [2]Biochem. Dept., Univ. of Washington, Seattle, WA; [3]Howard Hughes Med. Inst., Seattle, WA

Abstract: The close proximity of skin keratinocytes to sensory afferents, the expression by keratinocytes of multiple transducers of physical and chemical stimuli, changes in the expression levels of these transducers in pathological states, and the release by keratinocytes of substances capable of activating or sensitizing nociceptors have provided circumstantial evidence that keratinocytes might initiate acute pain responses. Yet, this concept has not been directly tested in vivo. Here, we describe a “chemogenetic” transgenic mouse strategy in which the capsaicin-

gated cation channel, Transient Receptor Potential Vanilloid 1 (TRPV1) is selectively, inducibly, and ectopically expressed in keratinocytes of mice lacking endogenous TRPV1. In vitro, keratinocytes from these mice exhibit robust capsaicin-evoked calcium influx, whereas their sensory neurons are completely insensitive to capsaicin. Topical administration of capsaicin to these mice in vivo triggers spinal cord c-fos induction, acute pain-related behavior and mechanical hyperalgesia. Together, these findings demonstrate the sufficiency of keratinocyte activation for the initiation of pain and introduce a robust system for the dissection of interaction between keratinocytes and sensory afferents.

Title: 17(R)-resolvin D1 specifically inhibits epidermal TRPV3 ion channel leading to peripheral antinociception

Authors: *S. HWANG[1], S. BANG[1], S. YOO[1], T.-J. YANG[1], H. CHO[2]
[1]Grad Sch. Med., Korea Univ. Ansan Hosp. #3513, Gyeonggi-Do, Korea, Republic of; [2]Col. of Pharm., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Transient receptor potential ion channel vanilloid 3 (TRPV3) is expressed in epidermal keratinocytes and sensory neurons and plays an important role in thermal and chemical nociceptions in the periphery. The presence of TRPV3 inhibitors would improve our understanding of TRPV3 function and help to develop receptor-specific analgesics. However, little is known about physiological substances that specifically inhibit TRPV3 activity. Here, we investigated whether 17(R)-resolvin D1 (17R-RvD1), a naturally occurring pro-resolving lipid specifically affects TRPV3 activity. We examined the effect of 17R-RvD1 on sensory TRP

channels using Ca(2+) imaging and whole cell electrophysiology experiments in a HEK cell heterologous expression system, cultured sensory neurons and keratinocytes. We also examined changes in sensory TRP agonist-specific acute licking/flicking or flinching behaviours and mechanical and thermal pain behaviours using Hargreaves, Randall-Selitto and von Frey assay systems in the absence and presence of inflammation. We showed that 17R-RvD1 specifically suppresses TRPV3-mediated activity at nanomolar and micromolar concentrations. The voltage-dependence of TRPV3 activation by camphor was shifted rightwards by 17R-RvD1, which indicates its inhibitory mechanism is as a result of a shift in voltage-dependence. Consistently, TRPV3-specific acute pain behaviours were attenuated by locally injected 17R-RvD1. Moreover, the administration of 17R-RvD1 significantly reversed the thermal hypersensitivity that occurs during an inflammatory response. Knockdown of epidermal TRPV3 blunted these antinociceptive effects of 17R-RvD1. 17R-RvD1 is a novel natural inhibitory substance specific for TRPV3. The results of our behavioural studies suggest that 17R-RvD1 has acute analgesic potential via TRPV3-specific mechanisms.

Title: Tonic inhibition of trpv3 by mg^{2+} in mouse epidermal keratinocytes

Authors: J. LUO[1], R. STEWART[1], R. BERDEAUX[1], A. QIAN[1], *H. HU[2]
[1]Integrative Biol. and Pharmacol., UTHSC at Houston, Houston, TX; [2]Uthsc-Houston, Houston, TX

Abstract: The transient receptor potential vanilloid 3 channel (TRPV3) is abundantly expressed in epidermal keratinocytes and plays important roles in sensory biology and skin health. Mg^{2+} deficiency causes skin
disorders associated with pruritus under certain pathological conditions such as type 2 diabetes

mellitus. In this study, we investigated the effect of Mg^{2+} on TRPV3 in primary epidermal keratinocytes. Extracellular Mg^{2+} ($[Mg^{2+}]_o$) inhibited TRPV3-mediated membrane current and calcium influx. TRPV3 activation induced a calcium signaling pathway culminating in activation of the cAMP response element binding (CREB). TRPV3 inhibition by $[Mg^{2+}]_o$, the TRPV3 blocker ruthenium red or TRPV3 siRNA suppressed this response. In TRPV3-expressing Chinese hamster ovary (CHO) cells, both extracellular and intracellular Mg^{2+} inhibited TRPV3 single-channel conductance but not open probability. Neutralization of an aspartic acid residue (D641) in the extracellular pore loop or two acidic residues (E679, E682) in the inner pore region significantly
attenuated the inhibitory effect of extracellular or intracellular Mg^{2+}
on TRPV3-mediated signaling, respectively. Our findings suggest that epidermal TRPV3 is tonically inhibited by both extracellular and intracellular Mg^{2+}, which act on both sides of the channel pore loop. Mg^{2+} deficiency may promote the function of TRPV3 and contribute to the pathogenesis of skin diseases.

Abstract: Introduction
The treatment of bone cancer pain is challenging because its mechanisms still remain to be elucidated. This study investigated the contribution of TRPV2 activation to the bone cancer-induced pain behaviors using TRPV2 siRNA in a murine model of bone cancer pain.
Methods
The protocol for this study was approved by the Animal Care Committee of our institution. Male C3H/Hej mice were used in the experiment. Sarcoma cells were injected into the left femur medullary for the development of bone cancer pain. Mice received intrathecal (it) TRPV2 siRNA

or vector alone once a day for 3 consecutive days from day 14 after sarcoma injection Bone cancer pain-related behaviors were assessed before and from day 14 to day 21 after sarcoma injection. The quantification of spontaneous flinches was used to measure ongoing pain. Limb use during ambulation and weight bearing were assessed as indications of movement-evoked pain. In some mice, expression of TRPV2 in DRGs was evaluated using Western blot analysis.
Results
Western blot analysis showed that it TRPV2 siRNA significantly reduced TRPV2 expression in lumbar DRGs compared to the vector alone at day 17 after osteosarcoma injection. Mice exhibited bone cancer-related pain behaviors, including spontaneous flinches, impaired limb use during ambulation, and impaired weight bearing during spontaneous standing at day 14 after sarcoma injection. It vector alone did not affect the 3 bone cancer-related pain behaviors. On the other hand, it TRPV2 siRNA significantly improved limb use and weight bearing but not the number of spontaneous flinches.
Summary and conclusion
The results of this study showed that primary afferent-expressing TRPV2 was involved in bone cancer-induced movement-evoked pain but not ongoing pain.

Title: Delta-opioid receptors are involved in the central antinociceptive effect of high doses of oxycodone in mice

Authors: P.-P. YANG[1,2], G.-C. YEH[1], P.-Y. LAW[3], H.-H. LOH[3], *P.-L. TAO[4,2]
[1]Grad. Inst. of Med. Sci., Taipei Med. Univ., Taipei, Taiwan; [2]Dept. of Pharmacol., Natl. Def. Med. Ctr., Taipei, Taiwan; [3]Dept. of Pharmacol., Univ. of Minnesota, Minneapolis, MN; [4]Inst. of Population Hlth. Sci., Natl. Hlth. Res. Inst., Zhunan, Taiwan

Abstract: Oxycodone has been used clinically for over 80 years. While it is known as a μ-opioid receptor agonist, Ross and Smith (1997) reported the antinociceptive effects of oxycodone (171 nmol, i.c.v.) are induced by putative κ-opioid receptors in SD rat. In this study, we have used mu-opioid receptor knock-out (MOR (-/-)) mice to investigate this issue. We found that systemic administration of oxycodone (above 40 mg/kg, s.c.) could induce significant antinociceptive effect in MOR(-/-) mice by the tail flick test. Either kappa-opioid receptor antagonist (nor-BNI, 20 mg/kg, s.c.) or delta-opioid receptor antagonist (naltrindole, 1 mg/kg, s.c.) could partially block this effect. In order to exclude the possible effect of oxycodone metabolites, we have injected oxycodone directly to brain by intracerebroventricular (i.c.v.) injections. We found that oxycodone induced the antinociceptive effect at doses above 50 nmol in MOR (-/-) mice. Delta-opioid receptor antagonists (naltrindole at 10 nmol or ICI 154,129 at 20 micro g) completely blocked the supraspinal antinociceptive effect of oxycodone in MOR (-/-) mice. These data indicated that delta opioid receptors are involved in the central antinociceptive effect of oxycodone at high doses.

Title: Differential role of beta-arrestin 1 and 2 on ligand-directed trafficking of the delta opioid receptor

Authors: A. A. PRADHAN[1], M. L. SMITH[1], W. WALWYN[1], A. BANA[1], B. L. KIEFFER[2], *C. J. EVANS[1]
[1]UCLA, LOS ANGELES, CA; [2]IGBMC, ILLKIRCH, France

Abstract: G protein coupled receptors exist in multiple conformations, and agonists can stabilize different active states. These specific ligand-induced receptor conformations result in distinct receptor-effector complexes, which initiate diverse signaling and trafficking events. This concept, referred to as ligand-directed signaling or functional selectivity, has important biological and therapeutic implications. Delta opioid receptors are currently being developed for the treatment of chronic pain and emotional disorders. Convergent evidence from a number of in vitro and in vivo studies has revealed functional selectivity at the delta opioid receptor. Specifically, we compared agonists with similar binding and analgesic properties, but high-(SNC80) or low-(ARM390) internalization potencies. We found that following chronic administration two distinct forms of tolerance were observed depending on the internalization property of the agonist. SNC80 produced a generalized tolerance resulting in receptor downregulation throughout the central and peripheral nervous systems. In contrast, ARM390 produced an analgesic specific tolerance at the level of the dorsal root ganglia. We recently examined the effects of SNC80 and ARM390 in beta-arrestin 1 and beta-arrestin 2 knockout mice. The behavioral effects of SNC80, but not ARM390, were potentiated in beta-arrestin 1 knockout mice, and these mice did not show receptor desensitization to this particular agonist. In contrast, in beta-arrestin 2 knockout mice, the effects of SNC80 were unaffected, whereas the properties of ARM390 were adversely affected. These results suggest that high and low internalizing delta opioid receptor agonists differentially recruit beta-arrestins, resulting in divergent biological effects.

Abstract: We recently developed a new mu-opioid receptor agonist amidino-TAPA, which shows extremely potent antinociception by systemic administration. Unlike other mu-opioid receptor agonists, amidino-TAPA does not show rewarding effect at antinociceptive doses. However, in prodynorphin-deficient mice, amidino-TAPA shows potent rewarding effect. The evidence suggests that amidino-TAPA is a potent analgesics lacking psychological dependence liability by releasing the endogenous kappa-opioid peptides. In the present study, antinociceptive mechanism of amidino-TAPA in supraspinal site was described to investigate the underlying mechanism for lack of the psychological dependence liability for amidino-TAPA. Amidino-TAPA showed extremely high affinity and relatively high selectivity for mu-opioid receptors in opioid receptor binding assays. However, the antinociception induced by i.c.v.-administered amidino-TAPA was attenuated by i.c.v. pretreatment with kappa-opioid receptor antagonist in addition with mu-opioid receptor antagonist. Moreover, i.c.v. pretreatment with antisera against endogenous kappa-opioid peptides dynorphin A and dynorphin B attenuated the antinociception induced by amidino-TAPA. The results suggest that amidino-TAPA given supraspinally stimulates novel mu-opioid receptor, which subsequently causes the release of dynorphins to produce antinociception. Although only one gene of mouse mu-opioid receptors (MOR-1) has been identified, more than 30 of splice variants for MOR-1 have been reported. In mice the splice variants containing exon-1 and exon-13 of MOR-1 have been desensitized using the exon-specific antisense oligodeoxynucleotide, the supraspinal antinociception induced by both amidino-TAPA and morphine was attenuated. The antinociception induced by amidino-TAPA, but not morphine, was also attenuated by the desensitization of MOR-1J and MOR-1L, exon-12 and exon-14 containing splice variants, respectively. Moreover, in the condition MOR-1J was desensitized, the inhibiting effect of antiserum against dynorphin A on amidino-TAPA-induced antinociception was disappeared. In contrast, the inhibiting effect of antisera against dynorphin A and dynorphin B was disappeared in the condition MOR-1L was desensitized. The present results suggest that the release of endogenous kappa opioid peptides by amidino-TAPA in supraspinal site is mediated through the activation of MOR-1J or MOR-1L. The supraspinal release of dynorphins by amidino-TAPA via activation of MOR-1J and MOR-1L may be involved in the lack of the psychological dependence liability for amidino-TAPA.

Title: Involvement of RF-amide peptides in the modulation of nociception and analgesic effects of opiates

Authors: *F. SIMONIN[1], J.-P. HUMBERT[1], I. BERTIN[1], B. PETIT-DEMOULIÈRE[2], H. MEZIANE[3], F. BIHEL[4], M. SCHMITT[4], J.-J. BOURGUIGNON[4], K. ELHABAZI[1]

Abstract: Mammalian RF-amide peptides are encoded by five different genes and act through five different G protein-coupled receptors. Neuropeptides SF and VF (NPSF and NPVF, also called RFRP1 and RFRP3) have been proposed to represent endogenous peptides for NPFF1 receptor, neuropeptides AF and FF (NPAF and NPFF) for NPFF2 receptor, and Prolactin releasing peptide (PrRP), Kisspeptin (or metastin) and 26RFa for GPR10, GPR54 and GPR103, respectively. However, results from several studies suggest that the selectivity of these peptides for their receptors is low and that expression patterns of these receptors and their corresponding ligands only partially overlap. In this study, we took advantage of the cloning of the five human RF-amide receptors to systematically examine their affinity for and their activation by all human RF-amide peptides. Binding experiments performed with membrane from CHO cells expressing these receptors indicated that GPR10, GPR54 and GPR103 display a remarkably good affinity and selectivity for their endogenous ligands. Conversely, we observed a high affinity of NPFF1 and NPFF2 receptors for all RF-amide peptides. Moreover, GTPgammaS and cAMP assays performed with cells expressing these receptors indicated that almost all RF-amide peptides efficiently activate NPFF1 and NPFF2 receptors. As NPFF has been shown previously to induce

hyperalgesia and/or to prevent the analgesic effect of morphine, we further performed a systematic analysis of the hyperalgesic and anti-morphine analgesic effect of mammalian RF-amide peptides in mice. Our results show that all RF-amide peptides induced hyperalgesia and/or prevented morphine analgesia following icv administration. Moreover, these effects were prevented by administration of RF9, a compound that blocks NPFF1 and NPFF2 receptors but not GPR10, 54 and 103. These results point to NPFF receptors as essential targets for the hyperalgesic and/or anti-morphine analgesic effect of exogenously administered RF-amide peptides. Taken together our data suggest that NPFF receptors could be endogenously activated not only by their known endogenous ligands (NPSF, NPVF, NPAF, NPFF) but also by other RF-amide peptides PrRP, Kisspeptin and 26RFa.

Title: Preclinical pharmacology of mu opioids - A comparison of morphine, oxycodone, hydrocodone and fentanyl in rodent pain models.

Authors: *I. Y. CHOI[1], C. ALI[1], J. EVANS[1], K. GOGAS[1], M. A. GUILLON[1], H. GURSAHANI[1], S. D. HARRISON[1], G. C. KIM[1], D. M. MCWEENEY[1], J. W. PFEIFFER[1], P. QUACH[1], J. RIGGS-SAUTHIER[2], P. C. TRINCHERO[1], T. A. RILEY[2]
[1]Nektar Therapeut., San Francisco, CA; [2]Nektar Therapeut., Huntsville, AL

Abstract: The pre-clinical pharmacological effects of mu opioid receptor agonists are well described in literature, but the experimental conditions employed often vary between studies. In most cases, pre-clinical pharmacological studies using mu opioids utilize intravenous or subcutaneous dosing routes. In this study, we evaluated the *in vivo* analgesic and side-effect profiles of commonly used mu opioids following oral dosing. In addition, we characterized the *in vitro* binding and function at the mu opioid receptor for each compound.
We examined binding affinities and efficacy of the opioids in membrane preparations or whole cells expressing human opioid receptors. Analgesia was measured in rodent models of acute (mouse acetic acid writhing, rat hot plate), persistent (rat formalin paw), inflammatory (rat

carrageenan-mechanical hyperalgesia, complete Freunds adjuvant-mechanical hyperalgesia) and neuropathic (rat spinal nerve ligation) pain following oral dosing of the selected mu receptor opioids. Mu opioid receptor mediated side effects were evaluated using the mouse gastrointestinal transit model and the rat Rota-rod test.
The *in vitro* rank order binding affinities were morphine (4.6 ±0.2 nM) > fentanyl (9.7 ±0.6 nM) > oxycodone (16 ±0.6 nM) > hydrocodone (113.4 ±18.7 nM). All of the mu opioids were analgesic across the panel of rodent pain models with fentanyl being the most potent agonist across these tests. As expected, in rodent models of gastrointestinal transit and motor coordination, all four agonists produced some level of impairment. The rank order potencies for side-effect profiles however, did not directly correlate to the analgesic potency. For example, the therapeutic indices for fentanyl and morphine with respect to mouse acetic acid writhing and mouse gastrointestinal transit were ~30 and ~3 respectively.
Taken together, these data show that orally administered mu opioid agonists are potent analgesics that produce complete suppression across a panel of rodent pain models, but differ in their therapeutic indices relative to their mu opioid mediated side-effects. These data will be useful in further benchmarking and differentiating the pharmacological activities of novel oral opioid agonists.

Title: Assessing the effects of peptide helicity and linker flexibility on opioid receptor binding and antinociceptive efficacy of endorphin-based glycopeptides

Authors: L. ST. LOUIS[1], Y. LI[2], J. BIDLACK[3], R. POLT[2], *E. J. BILSKY[4]
[1]Neurosci., Univ. of New England, Biddeford, ME; [2]Chem., Univ. of Arizona, Tucson, AZ; [3]Pharmacol., Univ. of Rochester, Rochester, NY; [4]Univ. New England, BIDDEFORD, ME

Abstract: Our group has previously demonstrated that glycosylation of small enkephalin-based peptides (i.e., glycopeptides) can significantly increase their stability, blood-brain barrier transport and systemic antinociceptive potency. Recently we have modified much larger endorphin- and dynorphin-based peptides to explore the delivery of these larger molecular weight compounds into the central nervous system. The current research explores two key aspects of these glycopeptides: (1) the flexibility of the linker segment between the core enkephalin message region and the larger address segment of the molecule, and (2) the effects of varying helicity in the address segment. The helicity was varied at two positions in the address segment to promote or inhibit helix formation (alpha-aminoisobutyric acid, alanine or glycine), while flexibility was altered with other amino acid substitutions in the linker region (L- or D-Proline, L- or D-Alanine, GABA or DAVA). The degree of glycosylation (unglycosylated, monosaccharide or disaccharide) was studied to assess the effects on overall helicity and activity of the compound. Helicity affected the glycopeptides in predictable ways as measured by circular dichroism (CD) in different solvents (H2O, CF3CH2OH and SDS micelles). In general, most of the analogs retained high affinity for mu, delta and kappa opioid receptors, and displayed potent antinociceptive effects when administered intracerebroventricularly (i.c.v.) to mice in the 55°C tail-flick assay. Exceptions included the linker substitution of D-Proline along with other the less flexible linkers. Surprisingly, a number of these glycopetides produced dose-related antinociception when administered intravenously (i.v.). These data indicate that a balance in hydrophilicity/hydrophobicity, helicity and linker flexibility resulted in optimal potency/efficacy following systemic administration. These studies are guiding the development of peptide-based therapeutics to overcome historical obstacles to CNS delivery.

Title: The effect of naltrexone on neuropathic pain in mice locally transfected with the mutant mu-opioid receptor gene in spinal cord

Authors: *J. KAO[1], P.-Y. LAW[2], H. H. LOH[2], P.-L. TAO[3]
[1]Natl. Def. Med. Center/Graduate Inst. of Life Sci., Taipei City, Taiwan; [2]Dept. of Pharmacol, UM Med. Sch., Minneapolis, MN; [3]Div. of Mental Hlth. & Addiction Med., Natl. Hlth. Res. Inst., Miaoli, Taiwan

Abstract: The opioid antagonists, such as naloxone and naltrexone, exhibited agonistic properties in the mutated mu-opioid receptor, MORS196ACSTA, in which the conserved Ser196, Thr327, and Cys330 were mutated to Ala, Ala, and Ser, respectively. In our previous study, systemic naloxone (10 mg/kg, s.c.) elicited antinociceptive effect (determined by tail-flick test) without the induction of tolerance, dependence, and rewarding effect in mice 2 weeks after intrathecal administration of dsAAV2-MORS196ACSTA-EGFP. In the present study, we further investigated whether this antinociceptive paradigm could be effective in mice with neuropathic pain. The spinal nerve ligation (SNL) surgery was performed on mice 3 or 4 weeks after intrathecal injection of the lentivirus which carried the gene of MORS196ACSTA-EGFP (called LV-MORS196ACSTA). The von Frey test and tail flick test were used to detect the anti-allodynic and antinociceptive effects of systemic naltrexone before and after gene transfection. After 14 days of naltrexone or morphine treatment (10 mg/kg, s.c., q.d.), the natural withdrawal signs were counted at 22 and 46 hours after the last drug injection. Our results showed that the paw withdrawal pressure and tail flick latency increased after naltrexone (10 mg/kg, s.c.) or morphine (10 mg/kg, s.c.) treatment in mice transfected with LV-MORS196ACSTA in spinal cord. However, chronic treatment of morphine (10 mg/kg, s.c., q.d.) but not naltrexone (10 mg/kg, s.c., q.d.) induced natural withdrawal signs. These data imply that systemic injection of naltrexone may have therapeutic potential for chronic neuropathic pain without the development of dependence after the gene therapy with the expression of MORS196ACSTA in the spinal cord.

Title: Ketamine co-administration increases morphine brain concentrations

Authors: T. O. LILIUS[1], V. JOKINEN[1], P. V. RAUHALA[1], *E. A. KALSO[2]
[1]Pharmacol., Inst. of Biomedicine, Univ. of Helsinki, Helsinki, Finland; [2]Anaesthesia & Intersive Care Med., Helsinki Univ. Central Hosp., Helsinki, Finland

Abstract: Ketamine is widely used in perioperative analgesia with morphine. Here we focus on the effect of ketamine on morphine metabolism and on the effects of ketamine on the development of hyperalgesia in a rat model of postoperative pain (Brennan's model). Morphine is metabolized to morphine-3-glucuronide (M3G) by UDP-glucuronosyl transferase (UGT) 2B1 in rodents. M3G has hyperalgesic effects through mechanisms not related to opioid receptors. Therefore, the metabolism of morphine to M3G is considered harmful. Because ketamine has been shown to inhibit UGT2B1 *in vitro* we studied the effects of ketamine on morphine metabolism and brain concentrations in the rat.
Sprague-Dawley (SD) rats (n = 5) received subcutaneous racemic ketamine (30 mg/kg) with or without 4 mg/kg morphine. Tissue samples were collected at 30 minutes. In the postoperative pain model, SD rats (n = 6) were subjected to a plantar incision in the hindpaw in isoflurane anesthesia. Subanesthetic ketamine (10 mg/kg subcutaneously) was administered at timepoints -20, 0, 60 and 180 minutes relative to the time of the incision. Primary hyperalgesia was measured with a dynamic plantar aesthesiometer after 60 and 180 minutes of the surgery and on postoperative days 1-5.
Ketamine co-administration significantly increased the concentration of morphine in the liver (by 410%) and in the brain (by 22%) but not in the serum (by 10%). The concentration of M3G was significantly decreased in the liver (by 59%) but not in the serum (by 50%) or in the brain (by 44%). No M6G was detected as expected. In the postoperative pain model, the mean force for eliciting the withdrawal response at baseline was 39.6 ± 5.9 g in the saline control group, and after the surgery the threshold force was at its lowest at 180 min (17.6 ± 5.2 g). It returned to the baseline level by postoperative day 4. The administration of ketamine did not significantly alter the development of primary hyperalgesia in this model.
The present results suggest that ketamine increases the brain concentration of morphine and inhibits the formation of M3G, which may contribute to the positive effects of ketamine on morphine analgesia. In the postoperative pain model ketamine did not show antihyperalgesic properties.

Title: BU 08073, a kappa, delta, and NOP antagonist with partial agonist activity at mu opioid receptors, can attenuate antinociception induced by kappa and mu opioid agonists

Authors: *T. V. KHROYAN[1], L. TOLL[2], W. E. POLGAR[1], G. CAMI-KOBECI[3], S. M. HUSBANDS[3]
[1]SRI Intl., Menlo Park, CA; [2]Torrey Pines Inst. for Mol. Studies, Port St. Lucie, FL; [3]Univ. of Bath, Bath, United Kingdom

Abstract: BU 08073 is a buprenorphine analog that binds with high affinity to mu, delta, kappa, and NOP opioid receptors, with Ki values of less than 10 nM at each site. BU 08073 has very low efficacy (less than 10% relative to full agonists) at delta, kappa, and NOP receptors. At mu receptors BU 08073 has moderate efficacy but high potency (EC50 2.9 nM, % stimulation 31.9%), having both higher efficacy and potency than buprenorphine, but having potentially lower brain penetrance compared to buprenorphine. We examined the effects of a single injection of BU 08073 on the tail flick assay, alone or as a pretreatment to morphine or U 50,488 administered 1-h to 10 days post injection from BU 08073. Surprisingly, an acute injection of BU 08073 does not increase tail flick latency in mice at any time point. Despite moderate efficacy at mu receptors, BU 08073 blocks analgesic activity of both morphine (mu-mediated) and U50-488 (kappa-mediated). However, the kinetics of inhibition of opiate-mediated analgesia are unusual. At 1-h post injection BU 08073 is inactive and does not alter mu or kappa-mediated antinociception. However, 6-h following an injection of BU 08073 (3 mg/kg) both morphine and U 50,488-induced analgesia are blocked. BU 08073 still blocks U 50,488 antinociception for 3 days presumably by acting as an antagonist at the kappa receptor. BU 08073 can block morphine-induced antinociception for up to 6 days presumably through its activity at the mu receptor. BU 08073 was also tested for anxiolytic or anxiogenic activity using the elevated zero-maze. BU 08073 alone decreased the time spent in the open quadrant, indicating anxiogenic activity. Surprisingly, a single injection of BU 08073, given as a pretreatment, induced anxiolytic activity for up to 10 days when mice were tested one hour after administration of the anxiogenic compound U 50-488. The reason this compound has no antinociceptive activity, in the tail flick assay, despite greater efficacy at mu receptors than buprenorphine and other mu-opioid partial agonists is unclear. The mechanism by which two anxiogenic compounds can become anxiolytic is also perplexing, however, both of these phenomena probably have to do with the slow onset of action and unusual kinetics of BU 08073.

Title: Group III mGluR-selective agonist potentiates morphine-induced inhibition of sensitized peripheral nociceptors.

Authors: *A. BAKER, S. CARLTON
Neurosci and Cell Biol, Univ. of Texas Med. Br., Galveston, TX

Abstract: Morphine is widely used to treat acute and chronic pain but causes significant deleterious side effects when taken in high doses or for long periods of time. Current studies aim to establish receptor groups and agonists that might potentiate analgesic efficacy of morphine at low doses in order to minimize side effects. One receptor family of interest is the metabotropic glutamate receptors (mGluRs) of which intrathecal and systemic application of Group III agonists have been established to potentiate morphine analgesia. In this study, we aimed to determine if peripheral administration of a Group III agonist potentiates morphine analgesia in acute inflammation. We employed behavior, electrophysiology, and immunohistochemistry techniques to examine the Group III mGluR agonist L-AP-4 plus morphine. In a model of peripheral inflammatory pain (i.e. inflammatory soup (IS) intraplantar), we obtained individual IC50s based on sensitivity to a heat stimulus (Hargreaves plantar test) for morphine (1, 10, 15, 20 mM) and L-AP4 (0.1, 1, 3, 10 µM) after intraplantar injection in the rat hindpaw. Isobolographic analysis of responses to thermal stimuli was conducted to determine the combined IC50 and to reveal if the relationship was synergistic, additive, or antagonistic. Preliminary results indicated that L-AP-4 synergistically potentiated morphine anti-hyperalgesia. Similar experiments were conducted in the *in vitro* skin-nerve preparation to determine if the

combination decreased sensitization at the nociceptor level. Morphine alone, L-AP-4 alone, and the combination were applied to sensitized fibers and responses to thermal and mechanical stimuli were assessed. Preliminary results suggest that the combination reduced mechanical sensitization. We also aimed to examine the anatomical basis underlying the relationship of Group III mGluRs and morphine by double-labeling dorsal root ganglion (DRG) cells for Group III mGluR8 and the mu opioid receptor (μOR). Data indicated that the receptors are co-localized in 28-55% of small and medium DRG cells, which are generally considered to be nociceptors. This will be further confirmed via triple-labeling DRG cells with mGlur8, μOR and either TRPV1 or Isolectin B4. The co-localization evidence hints that the Group III plus morphine combination works through an intracellular mechanism. Overall, preliminary data suggest that peripheral Group III mGluR activation increases morphine-induced inhibition of inflamed nociceptors via modulation of an intracellular pathway.

Title: Characterization of spontaneous activity in nociceptive fibers from glabrous skin of morphine treated-mice

Authors: *D. HOGAN[1], J. A. MORON CONCEPCION[2], S. M. CARLTON[1]
[1]Neurosci. & Cell Biol., Univ. Texas Med. Br., Galveston, TX; [2]Dept Anesthesiol., Columbia Univ. Med. Ctr., New York, NY

Abstract: Repeated use of opioids, either for treatment of chronic pain or as a drug of abuse, induces neuroadaptive changes forming the neurobiological basis for drug dependence and addiction. One consequence of morphine use is increased pain sensitivity (allodynia and/or hyperalgesia), documented in both animal and clinical studies. We analyzed this phenomenon, recording from nociceptors in a skin-nerve preparation. Adult male C57BL6 mice were injected with escalating doses of morphine (5, 8, 10, and 15 mg/kg) or saline every 12h for 48h. Mice were sacrificed ≈16h following the last injection. Recordings were obtained from C and A-delta

fibers innervating the hind paw. Spontaneous activity (SA) was defined as activity greater than 2 standard deviations above background for that fiber type from saline-treated mice. SA was measured during an initial 2 min period and during 5 min periods between heat, cold, and mechanical testing.
Forty fibers (20.4% of total fibers) from 16 of 26 morphine-treated mice showed SA, versus only 2 fibers (1.5%) from 2 of 30 saline-treated mice. In morphine mice, 26.4% of C fibers and 17.8% of A-delta fibers exhibited SA. There were 61 SA events from the 40 morphine fibers. Twelve SA events were characterized by regular firing (average 1.9 Hz.) Seventeen events were characterized by burst-like activity of > 10Hz. The remainder of SA events had slower, irregular firing patterns. Nineteen SA events occurred in the first 2 min recording period before any stimulation. Of the remaining 42, 17 were post-heat, 8 post-cold, and 17 post-mechanical stimulation. Of the post-stimulus events, 17 consisted of continued firing after the end of the stimulus (1 heat, 6 cold, 10 mechanical.) The other 25 post-stimulus SA events occurred an average of 102.7s (range 12-340s) after the end of the stimulus (16 heat, 2 cold, 7 mechanical.) There was no correlation between the type of fiber (heat or cold responsive) and the occurrence of SA events, e.g., heat responsive fibers could show abberent responses after heat, cold or mechanical stimulation. Neither was there any preference for C or A-delta fibers in any category of SA.
In morphine-treated mice, aberrant firing of nociceptors in the absence stimulation could underlie spontaneous pain and contribute to increased pain sensitivity. Sustained firing post-stimulation could underlie hyperalgesia and allodynia. Importantly, this peripheral SA is most likely driving central sensitization which also contributes to hyperalgesic and allodynic states. In human patients, nociceptor activity that is either spontaneous or post-stimulus is likely to be interpreted as pain, and could contribute to opioid-induced hyperalgesia.

Title: Analgesic efficacy estimates for intrathecally administered opioid agonists in mice

Authors: *S. JASWAL, M. R. GAJJAR, D. M. NAVANI, B. C. YOBURN
Pharm. Sci., Col. of Pharmacy, St. John's Univ., Jamaica, NY

Abstract: The present study used a quantitative model to estimate the analgesic efficacy in mouse spinal cord of four opioid agonists (sufentanil, DAMGO, oxycodone and fentanyl) administered intrathecally (IT). Initially, the time of peak analgesic effect and EC_{50} for each drug were determined using the tailflick assay. Peak effect was 5, 15, 10 and 10 min for sufentanil, DAMGO, oxycodone and fentanyl respectively. The EC_{50}s were: sufentanil 1.8 ng/mouse; DAMGO 0.5 ng/mouse; oxycodone 0.38 µg/mouse; fentanyl 33.0 ng/mouse. ED_{50}s determined using quantal data indicated similar relative potencies. Analgesic efficacy was estimated using the receptor depletion approach with the irreversible µ-opioid receptor antagonist cloccinamox. The operational model of agonism was used to calculate the efficacy parameter (Tau: τ). This approach utilizes graded data (mean latency in sec) and estimation of EC_{50}s. Mice were treated with vehicle (dH_2O containing ≈ 4% DMSO) or cloccinamox (6.4 - 12.8 mg/kg, i.p.), and 24 hrs later IT dose-response studies were conducted for sufentanil, DAMGO, oxycodone and fentanyl. Cloccinamox dose-dependently reduced the potency of all drugs. Cloccinamox (6.4 mg/kg) increased the EC_{50} by 3.9, 4.8, 4.8 and 19-fold for sufentanil, DAMGO, fentanyl and oxycodone respectively. Cloccinamox (12.8 mg/kg) resulted in flat dose-response functions for all drugs except sufentanil, for which the shift in the EC_{50} was 4.7-fold. These shifts in EC_{50}s suggest that sufentanil, fentanyl and DAMGO are higher analgesic efficacy opioids than oxycodone in the mouse spinal cord. When these preliminary data were used to estimate efficacy using the operational model of agonism, the τ values were 62, 54, 47 and 24 for fentanyl, DAMGO, sufentanil and oxycodone; respectively. Studies estimating τ after systemic opioid agonist administration have reported τ values of 58 and 20 for fentanyl and oxycodone respectively, which is in general agreement with the present estimates in spinal cord. The estimation of analgesic efficacy of spinally administered opioids may be useful to characterize the potential utility of opioid agonists used clinically for spinal analgesia.

Title: Analgesic and neuroexcitatory effects of hydrocodone and its metabolites

Authors: *D. M. NAVANI, S. JASWAL, B. C. YOBURN
Pharmaceut. Sci., Col. of Pharmacy, St. John's Univ., Jamaica, NY

Abstract: Hydrocodone (HYC), an opioid agonist for moderate to severe pain, is metabolized to hydromorphone (HYM) and norhydrocodone (NHYC). HYM is believed to be pivotal in HYC induced analgesia, while NHYC is considered to contribute minimally. Although NHYC levels in human plasma and urine following oral HYC may exceed that of HYM, it is not clear if this may impact on analgesic or toxic effects. In this report, we examined analgesia and toxicity produced by NHYC, HYC and HYM in mice. Peak analgesia (tailflick) following s.c. HYC, HYM and NHYC was 15, 45, 45 min respectively and analgesic ED_{50}'s (95%CL) were: HYM: 0.3 mg/kg (0.2-0.4); HYC: 1.4 mg/kg (0.9-2.0); NHYC: 95.8 mg/kg (63.7-146.2). Next, spinal intrathecal (IT) analgesia was determined. The IT ED_{50}'s (95%CL) were: HYM: 7.0 ng/mouse (0.5-100.5); HYC: 1.9 µg/mouse (0.2-48.8). IT NHYC did not produce antinociception at any dose. Naltrexone (1 mg/kg, s.c.) antagonized s.c. analgesia for all three opioids and IT analgesia for HYC and HYM. IT naltrexone (10 µg/mouse) antagonized IT analgesia for HYC and HYM. All compounds produced tonic-clonic seizures at higher IT doses. The ED_{50}'s (95%CL) to induce seizures were: NHYC: 4.3 µg/mouse (2.9-6.8); HYM: 5.2 µg/mouse (3.5-8.3); HYC: 19.4 µg/mouse (12.6-31.6). Naltrexone (1, 10, 30 mg/kg, s.c. or 10 µg/mouse, IT) did not antagonize seizures induced by NHYC (10 µg/mouse, IT). The ratio of IT ED_{50}'s for analgesia and seizures were: HYM: ≈ 740; HYC: ≈ 10; (as noted, NHYC lacked an IT analgesic effect). Displacement binding studies in spinal cord indicated that K_i values (95%CL) for µ (DAMGO) and δ (DPDPE) receptors were, respectively: HYM: 1.3 nM (1.1-1.4), 54.7 nM (27.0-110.9) δ/µ = 42 ; HYC: 76.3 nM (57.4-101.5), 1385 nM (708.5-2706) δ/µ = 18; NHYC: 189.1 nM (127.1-281.4), 4055 nM (2865-5738) δ/µ = 21. Taken together, all compounds produced systemic analgesia, although only IT HYC and HYM produced spinal analgesia. All compounds produced seizures at higher IT doses. Analgesia induced by all compounds was opioid receptor mediated, while seizures induced by IT NHYC were non-opioid mediated. Finally, all three compounds demonstrated µ versus δ-opioid receptor selectivity. These results suggest that NHYC possesses systemic analgesic activity which may contribute to HYC analgesia. However, the finding of spinal neuroexcitatory effects raises the possibility that with repeated administration of HYC, NHYC levels may rise and produce unwanted non-opioid toxicity.

Title: Opioid-induced hyperalgesia is associated with increased MOR-1K gene expression levels

Authors: *F. OLADOSU[1], M. S. CONRAD[3], D. PRUSIK[2], J. GAUTHIER[2], G. SLADE[2], N. U. RASHID[2], L. DIATCHENKO[2], A. G. NACKLEY[2]
[1]Ctr. of Neurosensory Disorders, [2]Neurobio., Univ. of North Carolina At Chapel Hill, Chapel Hill, NC; [3]Neurosci., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Opioids commonly used in the treatment of acute and chronic pain have been reported to produce a paradoxical opioid induced hyperalgesia (OIH) in a subset of the population. Recent evidence indicates a potential role for MOR-1K, an alternative splice variant of MOR-1, in OIH. Unlike its parent receptor MOR-1 that mediates opioid analgesia via cellular inhibition, MOR-1K facilitates cellular excitation upon activation. Because of its opposing cellular effects, we hypothesized that MOR-1K contributes to OIH in genetically-susceptible individuals. To test this hypothesis, pain behavioral responses and MOR-1K gene expression were evaluated in three genetically diverse strains of mice (C57BL/6J, CXBK,129SV/EV) receiving subcutaneous injections of vehicle or escalating amounts of morphine sulfate (10, 20, 20, 40 mg/kg) over four days. Responses to mechanical and thermal stimuli were evaluated at baseline, before and following morphine administration on days 1-4, and following morphine cessation on days 5-7. In separate groups of mice, levels of MOR-1K gene expression in spinal cord and brain were measured at baseline and on days 1, 4, and 5. At baseline, C57BL/6J, 129SV/EV, and CXBK mice exhibited different pain sensitivity profiles in response to mechanical and thermal stimuli. Compared to the classic C57BL/6J inbred strain, 129SV/EV mice were the least pain sensitive, exhibiting the highest paw withdrawal threshold and the lowest degree of mechanical and thermal heat hyperalgesia. In contrast, CXBK mice were the most pain sensitive, exhibiting the lowest paw withdrawal threshold and the highest degree of mechanical and thermal heat hyperalgesia. Following morphine administration, C57BL/6J, 129SV/EV, and CXBK mice exhibited different analgesic and hyperalgesic response profiles. C57BL/6J mice displayed analgesia following morphine administration on days 1-4 and hyperalgesia following morphine cessation on days 5-7. 129SV/EV mice displayed analgesia following morphine administration on days 1-4, but failed to develop hyperalgesia at any time point. In contrast, CXBK mice failed to display analgesia, but developed pronounced hyperalgesia as early as day 3 and lasting through day 7. MOR-1K gene expression paralleled pain behavior in the two most extreme strains, such that 129SV/EV mice exhibited decreased expression on days 1 and 4, corresponding to their analgesic behavioral profile, and CXBK mice exhibited increased expression on day 4, corresponding to their hyperalgesic behavioral profile. Together, our findings implicate MOR-1K as a novel druggable target that contributes to the development of OIH.

Title: Spinal and supraspinal mechanisms of morphine hyperalgesia

Authors: *C. A. AROUT[1], M. CALDWELL[2], G. ROSSI[3], B. KEST[2]
[1]Dept. of Psychology, The Grad. Center, CUNY, New York, NY; [2]Dept. of Psychology, The Col. of Staten Island, Staten Island, NY; [3]Dept. of Psychology, C.W. Post, Long Island Univ., Brookville, NY

Abstract:
Chronic morphine infusion can cause a paradoxical hyperalgesic state in male and female mice that occurs independently of opioid receptor activity (Juni et al. 2006), but sex differences have been elucidated (Juni et al. 2010, Waxman et al. 2010). Whereas both sexes are rendered hyperalgesic by day 4, an acute intracerebroventricular injection of the noncompetitive NMDA receptor antagonist MK-801 reverses hyperalgesia in males after chronic infusion of a high morphine dose (50mg/ml), and both males and females after chronic morphine infusion of a low morphine dose (2mg/ml) (Juni et al. 2010). In contrast, a single intracerebroventricular injection of the selective melanocortin-1 receptor antagonist MSG606 reverses morphine hyperalgesia exclusively in females after chronic morphine infusion of a low morphine dose (Juni et al. 2010). Although we have shown that males and females possess both male- and female-typical hyperalgesic systems, and that subsequent recruitment of these mechanisms is hormonally regulated (Waxman et al. 2010), the precise neural substrates that underlie such processes is still nebulous. Accordingly, in the present study the aforementioned findings were subjected to replication with additional exploration of possible spinal and supraspinal involvement in the regulation of morphine hyperalgesia.

Title: Acute morphine activates satellite glial cells and up-regulates IL-1beta in dorsal root ganglia via MMP-9 to mask opioid analgesia

Authors: *T. BERTA[1,2], T. LIU[1,2], Y.-C. LIU[3,2], Z.-Z. XU[1,2], R.-R. JI[1,2]
[1]Anesthesiol., Duke Univ. Med. Ctr., Durham, NC; [2]Anesthesiol., BWH and Harvard Med. Sch., Boston, MA; [3]Natl. Cheng Kung Univ., Tainan City, Taiwan

Abstract: Despite well-known side effects, opioids are still the most used analgesics. It is clinically important to improve the analgesic efficacy of opioids. Activation of spinal cord glial cells such as microglia and astrocytes has been shown to cause chronic opioid-induced anti-nociceptive tolerance and hyperalgesia. However, it is unclear whether acute opioid treatment can activate glial cells in the peripheral nervous system. We examined acute morphine-induced activation of satellite glial cells (SGCs) and up-regulation of IL-1beta in dorsal root ganglia (DRGs), and further investigated the involvement of matrix metalloprotease-9 (MMP-9) in these opioid-induced peripheral changes.
Subcutaneous morphine injection (10 mg/kg) induced robust peripheral glial responses, as evidenced by increased GFAP expression in DRGs but not in spinal cords. Acute morphine treatment also increased MMP-9 expression in DRG neurons, IL-1beta expression in DRG SGCs, and IL-1beta activation in DRGs. Confocal analysis revealed a close proximity of MMP-9 and GFAP immunostaining. Importantly, morphine-induced DRG up-regulation of GFAP expression and IL-1beta activation was abolished after Mmp9 deletion or naloxone pre-treatment. Finally, acute morphine-induced analgesia was enhanced and prolonged after Mmp9 deletion or intrathecal injections of IL-1beta-selective siRNA.
In conclusion, MMP-9 could mask and shorten morphine analgesia via peripheral neuron-glial interactions. Targeting peripheral glial activation might prolong acute opioid analgesia.

Title: The delta-opioid receptor contributes to morphine tolerance in an animal model of chronic inflammatory pain

Authors: *L. HIPOLITO[1], H. BEAUDRY[2], A. GUPTA[3], L. DEVI[3], L. GENDRON[2], J. A. MORON CONCEPCION[1]

Abstract: Opioid use in chronic inflammatory pain is limited by the development of tolerance and unwelcomed side effects. Although the topic remains controversial, functional and physical interactions between the mu- (MOP) and the delta- (DOP) opioid receptors have been recently reported. Indeed, recent studies suggest that interactions between the MOP and DOP may play an important role in morphine-induced behavioral adaptations. In fact, blockade of the DOP or disruption of MOP/DOP heteromers was shown to enhance morphine-induced analgesia. Here, we investigated the regulation of DOP and the MOP/DOP heteromer during the development of morphine tolerance in a rat model of chronic inflammatory pain. We find an increase in the expression of DOP at the postsynaptic density fraction in the dorsal horn of the spinal cord in morphine tolerant rats and this effect is even more robust in the presence of chronic inflammation. In addition, ELISA studies using a selective MOP/DOP heteromer antibody show an increase in the levels of the MOP/DOP heteromer in the dorsal horn in morphine tolerant rats; interestingly this effect is even more dramatic during chronic inflammatory pain. Thus, our data show that the increase in the levels of postsynaptic DOP correlates with an increase in the DOP/MOP heteromer formation. Furthermore, behavioral analyses show that pretreatment (s.c. or i.t.) with the DOP antagonist, naltrindole, attenuates the development of morphine tolerance. Overall, our data show that the DOP play an important role during morphine tolerance, an effect further amplified in the presence of chronic inflammation. We also show that the increase in DOP levels is associated with an increase in the levels of the MOP-DOP heteromer in the spinal

cord. Altogether, our findings highlight the DOP as a key player in the development of morphine tolerance during chronic inflammation. Further studies are needed to analyze whether the above observed changes in DOP levels and MOP/DOP abundance are also observed in other components of the opioid-sensitive pain-modulating circuit and to define the exact consequences of this phenomenon.

Title: Mu-opioid receptors switch NMDA receptors in primary afferents to a non-functional state

Authors: *J. G. MARVIZON[1,2], W. CHEN[2], J. A. MCROBERTS[2]
[1]VA GLA HS, LOS ANGELES, CA; [2]Med., UCLA, Los Angeles, CA

Abstract: NMDA receptors present in the central terminals of primary afferents elicit substance P release into the dorsal horn, but this requires phosphorylation of their NR2B subunit by a Src family kinase (SFK) (Chen et al., 2010, Neuroscience 166:924). We recently found that in naïve rats these NMDA receptors are in a dephosphorylated, non-functional state. However, in rats with chronic constriction injury (CCI) of the sciatic nerve (a model of neuropathic pain) these NMDA receptors become functional through a signaling cascade involving microglia activation, BDNF release and SFK phosphorylation. After CCI, these NMDA receptors gradually return to a non-functional state during a period of 3-7 days, suggesting that there is a signal leading to their dephosphorylation. Since mu-opioid receptors (MORs) in primary afferents also activate a SFK, we investigated whether MOR agonists could also turn the NMDA receptors into their functional state. We found the opposite: the MOR agonists DAMGO, morphine and endomorphin-2 abolished NMDA-induced substance P release from rat spinal cord slices (measured as neurokinin 1 receptor internalization). The inhibition by DAMGO was time-dependent, requiring a preincubation of the slices with DAMGO for at least 15 min, whereas DAMGO produced no effect when added together with NMDA. The effect of DAMGO was dose-dependent, with IC50 = 10 nM. The selective MOR antagonist CTAP (10 μM) shifted the dose-response of DAMGO

to the right (IC50 = 492 nM, Fig.), confirming the involvement of MORs. However, a similar inhibition of NMDA-induced substance P release was produced by the delta-opioid receptor agonist DPDPE (1 µM), but not by the GABAB receptor agonist baclofen (10 µM). The inhibition by DAMGO was abolished by the protein tyrosine phosphatase inhibitor BVT 948 (10 µM). This suggests that the MORs present in primary afferent terminals turn these NMDA receptors into a non-functional state by triggering the dephosphorylation of their NR2B subunit by a protein tyrosine phosphatase, reversing the effect of BDNF. This may contribute to the analgesic effect of opioids.

Title: The involvement of RhoA in the up-regulation mechanism of the intestinal P-glycoprotein by repeated orally administered etoposide

Authors: *T. KOBORI[1], S. HARADA[1], K. NAKAMOTO[1], S. KISHIOKA[2], S. TOKUYAMA[1]
[1]Dept. of Clin. Pharmacy, Sch. of Pharmaceut. Sci., Kobe Gakuin Univ., Kobe, Japan; [2]Dept. of Pharmacol., Wakayama Med. Univ., Wakayama, Japan

Abstract: *Aims*: Morphine is the most commonly used opioid analgesic for the treatment of pain and is known as a substrate of P-glycoprotein (P-gp), a drug efflux transporter. Recently, in early palliative care, the combined use of opioids and anticancer drugs which are substrate of P-gp for the treatment of cancer patients is increasing. Therefore, drug-drug interaction between opioids and anticancer drugs is known to be watched in the clinical field. We previously reported that repeated administration of oral etoposide (ETP) which is a substrate of P-gp, caused attenuation of the analgesic effect of oral morphine through the up-regulation of intestinal P-gp. However, the detailed up-regulation mechanism of intestinal P-gp by repeated administration of anticancer drugs is still unknown. Recent studies have revealed that RhoA, a small molecular G protein, is involved in the regulation of P-gp expression and activity. The activation of RhoA requires the translocation from cytosol to membrane and its membrane translocation is mediated by posttranslational modification via geranylgeranylation. Moreover, RhoA is known to be involved in various signaling pathways in response to anticancer drugs. Here, we examined the involvement of RhoA in the changes in the intestinal P-gp protein expression and its drug efflux activity induced by repeated administration of oral ETP.
Methods: Intestinall P-gp and RhoA protein expression levels were analyzed using western blot analysis. Rhodamine 123 (Rho123) efflux activity of intestinal P-gp was measured using the *in situ* closed loop method. The analgesic effect of oral morphine was determined with a tail-flick test.
Results: One day after repeated ETP treatment (10 mg/kg, p.o., once a day for 7 days), the analgesic effect of morphine (50 mg/kg, p.o.) was significantly attenuated with decrease in its levels in serum and brain. At the same time, the intestinal P-gp protein expression and Rho123 efflux activity were significantly increased. Moreover, repeated ETP treatment significantly increased RhoA protein expression in the intestinal membrane fraction but not in cytosol. Interestingly, rosuvastatin (5 mg/kg, p.o. once a day for 7 days), an inhibitor of RhoA translocation from cytosol to membrane, prevented these effects. Furthermore, ETP-induced attenuation of the analgesic effect of oral morphine was also significantly suppressed by rosuvastatin.
Conclusion: RhoA activation induced by repeated oral ETP treatment may regulate the changes in the intestinal P-gp protein expression and its drug efflux activity, leading to a decrease in the analgesic effect of oral morphine.

Title: Bifunctional nociceptin receptor agonists with mu opioid agonist activity show reduced tolerance development to their antinociceptive effects

Authors: *N. T. ZAVERI[1], T. V. KHROYAN[2], W. POLGAR[2], L. TOLL[3], V. B. JOURNIGAN[1], D. YASUDA[1]
[1]Astraea Therapeutics, LLC, Mountain View, CA; [2]SRI Intl., Menlo Park, CA; [3]Torrey Pines Inst. for Mol. Studies, Port St. Lucie, FL

Abstract: The use of mu-opioid agonists such as morphine as analgesics is often hampered by the development of tolerance to its anti-nociceptive effects, particularly during chronic use, necessitating increases in dosage, followed by sequelae of other undesirable side-effects. The nociceptin receptor NOP, the fourth member of the opioid receptor family, and its endogenous peptide ligand nociceptin/orphaninFQ (N/OFQ) have been shown to modulate several opioid-mediated activities, particularly in reward and nociceptive pathways. Intracerebroventricular injection of N/OFQ has been shown to decrease tolerance development to morphine-induced antinociception in rats, suggesting that activation of the NOP receptor system may reduce tolerance development to opioid-mediated antinociception. Further, we have shown that NOP receptor agonists decrease the rewarding effects of morphine in the place-conditioning paradigm. We have hypothesized that 'bifunctional' NOP agonists that also possess mu-opioid agonist activity could have anti-nociceptive activity, and a reduced propensity for opioid-related side-effects (such as reward and tolerance development). We have previously demonstrated that the bifunctional NOP/mu receptor partial agonist SR16435 produces dose-dependent antinociception and exhibits decreased tolerance development to its antinociceptive effects when administered over nine days, compared to morphine. In the present study, we further examined tolerance development to the antinociceptive effects of two other bifunctional NOP/mu agonists, AT-200 and AT-203, using the mouse tail-flick assay. The compounds were administered subcutaneously as daily injections for ten days. The results showed that tolerance developed to morphine antinociception (3 mg/kg) by the fourth day/injection, whereas tolerance did not develop to the antinociception produced by AT-200 or AT-203. When the NOP antagonist SB612111 was given as a pretreatment prior to daily injections of AT-200 and AT-203, tolerance to antinociception developed at a similar rate as that observed with morphine. These latter findings confirm that the inhibition of tolerance development in these bifunctional compounds is mediated by their NOP agonist activity. These results support the therapeutic application of such bifunctional NOP/mu agonists as non tolerance-developing analgesics. This work was supported by grants DA14026 and DA027811.

Title: Lack of opioid-adrenergic spinal analgesic synergy in δ-opioid receptor knock-out mice

Authors: *A.-J. CHABOT-DORE[1,2,3], M. MILLECAMPS[4,2], L. S. STONE[4,2]
[1]McGill Univ., Montréal, QC, Canada; [2]The Alan Edwards Ctr. for Res. on Pain, [3]The Integrated Program in Neurosci., [4]Fac. of Dent., McGill Univ., Montreal, QC, Canada

Abstract: Background: When co-administered to the spinal cord, agonists acting at α_2-adrenergic receptors (ARs) and opioid receptors (ORs) interact in a greater-than-additive (i.e. synergistic) manner to produce analgesia. The development of therapeutic approaches that exploit the combination of opioids and α_2-adrenergic agonists is currently limited by the lack of mechanistic knowledge on how these drugs interact at the spinal level. The OR family consists of three subtypes: δ (DOR), μ (MOR) and κ (KOR), all of which can have analgesic actions. It has been demonstrated that both DOR-selective agonists and MOR-selective agonists interact synergistically with α_2AR-selective agonists. However, the relative role of each subtype is not clear as studies have suggested that either DOR or MOR are the primary mediators of synergy with adrenergic agonists. It therefore remains unresolved if opioid-adrenergic synergy requires DOR activation, MOR activation, both or neither.
Objective: Evaluate the role of DOR in spinal opioid-adrenergic synergistic interactions.
Methods: 3-6 month old male WT mice (Charles River, C57Bl6) and DOR-KO mice (The Jackson Laboratory, B6.129S2-*Oprd1*^{tm1Kff}/J) with a deletion in the *Oprd1* gene were used in the substance P (SP) behavioral assay. Drugs were injected intrathecally with substance P (SP) and the inhibition of SP-induced nocifensive behaviors was calculated. Full dose response curves

were generated to evaluate the antinociceptive action of clonidine, morphine, deltorphin II (Delt II) and DAMGO, alone or in combinations. Isobolographic analyses were performed to determine if drug interactions were synergistic, additive or antagonistic.
Results: Clonidine, an α_2AR-selective agonist, interacted synergistically with morphine in WT mice but not in DOR-KO mice. The DOR-selective agonist, Delt II, was not efficacious in DOR-KO mice and did not enhance clonidine efficacy in DOR-KO mice. Clonidine's interaction with DAMGO, a MOR-selective agonist, was additive in both mouse strains.
Conclusion: Our results suggest that opioid-adrenergic synergistic interaction requires activation of DOR since a) synergy is absent when clonidine was combined with either morphine or Delt II in DOR-KO mice and b) the interaction between clonidine and DAMGO is additive in both WT and DOR-KO mice, confirming that MOR activation is not sufficient to produce opioid-adrenergic synergy. The development of combination therapies exploiting this interaction should include activation of DOR in order to take full advantage of the analgesic synergy between opioids and α_2-adrenergic agonists.

Abstract: Spinal analgesic synergy between agonists acting at opioid and adrenergic receptors has been well documented. We have recently shown that the requirement of protein kinase C-

epsilon (PKCε) for analgesic synergy can be used to classify such synergistic interactions as occurring either within a single pre-synaptic terminal, or across multiple neurons. Specifically, we have found that synergistic agonist combinations requiring delta opioid receptors (δORs) and alpha2A adrenergic receptors (α2A-ARs), which co-localize in terminals of peptidergic primary afferent nociceptors (PANs), require PKCε. Additionally, activation of PKCε is not required by combinations requiring receptors not co-localizing in the same neurons, such as those of a delta or mu opioid agonist or α2A-AR agonist paired with a α2C-AR agonist. Here we have used the hot-water tail-flick assay in wild-type mice (PKCε-WT) and mice genetically lacking PKCε (PKCε-KO) to evaluate combinations of agonists acting at δORs and mu opioid receptors (μORs) for the requirement of PKCε for spinal analgesic synergy. Agonists investigated include deltorphin, deltorphin I, deltorphin II, dermorphin, SNC80, DPDPE, leu-enkephalin, beta-endorphin, morphine and endomorphin II. More than a dozen combinations have been tested thus far and all produced analgesic synergy in PKCε-WT mice. Only two combinations, deltorphin I with morphine and deltorphin II with morphine, have shown PKCε dependence. This requirement correlates directly with the amino acid structure of the peptide agonist used. Deltorphin I, deltorphin II, deltorphin and dermorphin are all seven amino acid peptides. The most striking difference among these peptides is the a.a. in the fourth position. In position four, deltorphin I and deltorphin II both contain a negatively charged a.a. (aspartate and glutamate, respectively), whereas dermorphin and deltorphin contain a neutral and a positively charged a.a., respectively (glycine and histidine). This structural difference, along with the behavioral data, indicates that the interaction between a ligand and its receptor may dictate how that receptor interacts with other receptors or signaling molecules. Considering that μORs may be located on PANs where they could co-localize with δORs, or on secondary spinal cord neurons, it is not surprising that synergy between μOR and δOR agonists can occur through multiple mechanisms. In conclusion, these data indicate that analgesic synergy between δORs and μORs can occur through multiple mechanisms, and that specific ligand-receptor interactions may be necessary to facilitate synergy between receptors in the same neuron.

Title: Leptin replacement in the leptin deficient B6.V-Lep^{ob}/J mouse restores the antinociceptive properties of the adenosine A_1 agonist N^6-p-sulfophenyladenosine

Authors: S. L. WATSON, M. J. FRANK, C. J. WATSON, H. A. BAGHDOYAN, *R. LYDIC
Anesthesiol., Univ. of Michigan, Ann Arbor, MI

Abstract: The adenosine A_1 agonist N^6-*p*-sulfophenyladenosine (SPA) and the acetylcholinesterase inhibitor neostigmine bromide cause antinociception when microinjected into the pontine reticular formation (PRF) of C57BL/6J (B6) mouse (J Pain 10:836, 2009). The antinociceptive effects of SPA are concentration dependent and likely receptor mediated (J Pain 13:S45, 2012). These drugs do not have the same effect in congenic leptin-deficient B6.V-Lep^{ob}/J mice. Leptin replacement restores the antinociceptive properties of neostigmine in leptin-deficient mice (J Pain 10:836, 2009). Thus, leptin modulates pain transmission by cholinergic G protein coupled receptors (GPCRs) in the PRF. No previous studies have determined whether pain modulation by leptin is limited to cholinergic GPCRs or can be generalized to adenosine A_1 receptors. This study is testing the hypothesis that replacing leptin in the leptin deficient B6.V-Lep^{ob}/J mouse restores the antinociceptive response to SPA microinjected into the PRF. Adult male mice (n=5) were implanted with guide tubes aimed for the PRF. Antinociception was measured by paw withdrawal latency (PWL) to a thermal stimulus as quantified with an IITC Analgesia Meter. In separate experiments, each mouse received a 50 nL microinjection of saline (control) or SPA (500 pmol). PWL measurements (s) were taken at 10, 20, 30, 60, 90, and 120 min after the microinjection. After the initial set of microinjections, mice were implanted with Alzet osmotic pumps set to deliver 15 μg of leptin per day for 14 days. The microinjection protocol was repeated during weeks 1 and 2 of leptin replacement with each mouse receiving microinjections of saline and SPA in separate experiments. PWL measurements were expressed as percent maximum possible effect (%MPE) to account for individual mouse differences and the thermal stimulus cutoff time of 15 s. After the final experiment, microinjection sites were histologically confirmed to be within the PRF. Two-way ANOVA for repeated measures indicated a significant drug main-effect on %MPE ($F=14.1$; $df=1,16$; $p=0.0199$). Post hoc tests revealed a significant ($p < 0.05$) increase in %MPE caused by SPA in the leptin-replaced mice, but not in the leptin-naïve mice. Therefore, leptin restored the antinociceptive properties of SPA microinjected into the PRF. These data support the conclusions that 1) leptin modulation of pain is not limited to cholinergic GPCRs, and 2) leptin significantly alters SPA modulation of pain via adenosine A_1 GPCRs in the PRF.

Title: Chi shao (Radix Paeoniae Rubra): Anti-inflammatory and analgesic effects of Traditional Chinese Medicine in the rat formalin test

Authors: M. REEDY, *E. P. WIERTELAK
Neurosci. Studies, Macalester Col., SAINT PAUL, MN

Abstract: The immense catalog of compounds used in Traditional Chinese Medicine (TCM) offer a compelling source of new treatments for Western medicine. The present studies examined the analgesic and anti-inflammatory properties of chi shao (*Radix Paeoniae Rubra*), a drug widely used in TCM, in the rat formalin test pain assay. All studies were conducted in accordance with protocols approved by the Macalester Institutional Animal Care and Use Committee. In study 1, rats (Sprague-Dawley, Male, +110 days old) received either 20 mg/kg chi shao (P.O., delivered in 10 ml/kg suspension; experimental group) or equivolume vehicle (control group). All subjects received the suspension/vehicle by gavage 30 minutes prior to the onset of testing. Dilute (5%) formalin was then injected subcutaneously into the dorsum of the rats' right hind paws and three subsequent pain-associated behaviors were measured: lifting, shaking, and licking the affected paw. Formalin-induced behaviors were recorded for periods of 1-minute at 5-minute intervals across a 1-hour time course. Behavioral data for each of the three categories collected was collapsed across early/acute phase (first 25 minutes) and later/tonic phase (subsequent 35 minutes) for analysis. Our results indicated no differences between groups in any behaviors during the acute phase, whereas responding in the tonic phase revealed significant differences for licking behavior, as rats administered chi shao exhibited fewer licking behavior. A strong trend was also observed in shaking behavior, where rats administered chi shao exhibited significantly fewer shaking behaviors. Two additional studies to be discussed are currently underway at this time and investigate dose response and time-related characteristics of chi shao. While speculative, chi shao, which is known within TCM practice to be a viable, fast-acting, pain reliever, may offer some guidance for western medicine in the development of potential novel treatments for the control of moderate pain in humans.

Title: Anti-hiperalgesic efect of etanolic extract of Rhodiola rosea in the formalin test in diabetic rats

Authors: *R. M. MONTIEL-RUIZ, M. DÉCIGA-CAMPOS
Escuela Superior De Medicina, IPN, D.F., Mexico

Abstract: Diabetic neuropathy is one of the most common complications in diabetes mellitus and is associated with spontaneous pain, hyperalgesia and allodynia. Currently, there is no available therapies that fully control diabetic neuropathy-induced pain without significant negative side effects. In an attempt to have new therapeutic alternative, the researching medicinal plant extracts has been intensified in the last decade. *Rhodiola rosea* is a plant commonly used in Europe and Asia for its adaptogenic, anti-inflammatory and antioxidant properties. The aim of this study was to evaluate the antihyperalgesic effect of ethanol extract of *Rhodiola rosea* in experimentally diabetic rats. Male Wistar rats were diabetized with streptozotocin (50 mg/kg, i.p.), six weeks later they were pretreated with the extract of *Rhodiola rosea* and hyperalgesia was determined using the formalin test. The administration of 50 μL of formalin (0.5%) in the right hind paw produces a behavior characterized by flinching. Intraperitoneal administration of ethanol extract of *Rhodiola rosea* (1-100 mg/kg) produced an antihyperalgesic dose dependent effect (ED_{50}=46.2 mg/kg) in the formalin test in diabetic rats. The antihyperalgesic effect was also observed following the intraplantar administration of the extract plant concentrations ranging from 100 to 1000 μg/paw. The results suggest that the ethanol extract of *Rhodiola rosea* may be an alternative in the treatment of hyperalgesia associated to the diabetic neuropathy.

Title: N-acylethanolamine acid amidase (NAAA): A potential novel target for analgesic drugs

Authors: O. SASSO[1], C. MARTUCCI[1], N. REALINI[1], G. MORENO-SANZ[1], R. BERTORELLI[1], A. REGGIANI[1], *D. PIOMELLI[1,2]
[1]Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [2]Departments of Pharmacol. and Biol. Chem., Univ. of California, Irvine, CA

Abstract: Bioactive N-acylethanolamines, including the endocannabinoid anandamide and anti-inflammatory N-palmytoylethanolamine (PEA), are hydrolyzed to fatty acids and ethanolamine in animal tissues by the catalysis of fatty acid amide hydrolase (FAAH). More recently, N-acylethanolamine-hydrolyzing acid amidase (NAAA), another enzyme catalyzing the same reaction has been cloned. NAAA preferentially hydrolyzes PEA over others fatty acid ethanolamides. Previous studies have shown that PEA exerts profound anti-inflammatory and analgesic effects that are due to a large extent to activation of the nuclear receptor peroxisome proliferator-activated receptor-α (PPARα). We recently developed a selective and potent NAAA inhibitor, ARN077. In the present study we profiled up the in vitro pharmacology of ARN077 and its activity in both inflammatory and neuropathic pain models. Topical administration of ARN077 produced a significant reversal of UVB-induced thermal hyperalgesia as well as carrageenan-induced inflammation and mechanical allodynia after sciatic nerve ligation. When CB1 or CB2 antagonists were injected before ARN077, they did not block the anti-hyperalgesic effect of the NAAA inhibitor, whereas a PPARα antagonist completely reversed ARN077 activity.
Present findings suggest that ARN077 could have therapeutic benefit in inflammatory based cutaneous disease states.

Title: Evaluation of antinociceptive effect of novel cannabinoid receptor agonists from conus venom in neuropathic pain model.

Authors: *C. PEREZ[1], S. JERGOVA[1], S. GAJAVELLI[1], L. IMPERIAL[2], B. OLIVERA[2], J. SAGEN[1]
[1]Miami Project, Univ. of Miami, Miami, FL; [2]Univ. of Utah, Salt Lake City, UT

Abstract: With the limitations of current long-term pharmacotherapy for chronic pain, the identification of alternative approaches and new therapeutic targets is essential. Cannabinoid (CB) receptor agonists have emerged as potential therapeutic targets, as robust antinociceptive effects have been reported in various pain models. However, most of the available drugs that interact with CB receptors are derived from cannabis and considered clinically unacceptable for long-term therapy due to psychoactive side effects. Therefore specific compounds interacting with CB receptors without aversive side effects are of clinical interest. The venoms of marine snail genus *Conus* are a natural source of various peptides (conopeptides) with potent analgesic effects, some of them already FDA approved. In this study we evaluated the ability of several *Conus* venom extracts to interact with CB_1 receptor.
The venom extracts of six *Conus* species were analyzed in vitro. HEK293 cells expressing CB_1 receptors were treated with venom extracts for 30 minutes and the rate of CB_1 receptor internalization was analyzed by immunofluorescence. Results showed the highest rate of CB_1 internalization in HEK293 cells after treatment with venoms of *C. textile* and *C. miles*. HPLC fractions (seven per species) of these venoms were subsequently analyzed using a similar approach. Based on the analysis, C. *Tex* subfraction with the highest CB_1 agonist activity was evaluated in a formalin test. I.t. injection of the *C.tex* fraction reduced flinching/licking behavior during the second phase of formalin test. The results indicate the presence of CB_1 agonists within the *Conus* venom extract and their potential analgesic effects. To identify the nature of CB_1 agonists, the *C. Tex* fraction was treated with proteolytic enzymes. The effect of treatment on CB_1 internalization was subsequently evaluated. Results showed that proteotolytic treatment attenuated the ability of venom fraction to induce CB_1 receptor internalization. Further evaluation and purification of peptide compounds is under way. The final peptide compounds of screened venoms with CB_1 receptor affinity could subsequently be used as a new analgesic agent in recombinant cell or gene therapy approaches.

Title: The cannabinoid receptor agonist WIN 55,212-2 attenuates sensitization of C-fiber nociceptors in a murine model of cancer pain

Authors: *M. L. UHELSKI[1], D. M. CAIN[2], C. HARDING-ROSE[2], D. A. SIMONE[2]
[1]Univ. of Minnesota Twin Cities, Minneapolis, MN; [2]Univ. of Minnesota, Minneapolis, MN

Abstract:
Evaluating and managing pain related to cancer is a major clinical hurdle. Of the estimated 1.6 million new cancer patients diagnosed each year, between 30 and 60% will develop chronic pain related to tumor growth
and/or treatment. Progress towards understanding the physiological changes associated with pain related to tumor growth is essential for the development of novel therapies. In this study, we utilized a murine model of cancer pain in which osteolytic fibrosarcoma cells are injected directly into and around the calcaneous bone, producing mechanical, thermal, and cold hypersensitivity as the cells proliferate and the tumor enlarges. In addition, electrophysiological studies have identified pathological changes in peripheral nociceptors following tumor development. Behavioral studies in our laboratory demonstrated that local administration of the cannabinoid receptor agonist, WIN 55,212-2, attenuated mechanical hyperalgesia associated with tumor growth through cannabinoid receptors (CB1 and CB2). The purpose of the current study was to examine the impact of WIN 55,212-2 on the sensitization of cutaneous C-fiber nociceptors innervating the plantar surface of the hind paw following tumor cell implantation. Mechanical hyperalgesia of the tumor-bearing paw was confirmed with behavioral assessments prior to electrophysiology. Mice were then deeply anesthetized, the tibial nerve was exposed and action potentials from single afferent fibers were recorded using a teased fiber approach. Well-isolated nociceptors were classified by conduction velocity, and their responses to mechanical and heat stimuli were obtained before and every 15 min for 1 h after drug administration. WIN 55,212-2 (10 µg) or vehicle was injected into the receptive field in a volume of 10 µl. WIN 55,212-2 attenuated tumor-evoked spontaneous ongoing activity and reduced the number of impulses evoked by a suprathreshold von Frey monofilament (0.4 g). Mechanical response threshold was not affected. These results indicate that the attenuation of mechanical hyperalgesia produced by cannabinoids observed in behavioral studies involves a reduction in the sensitization of C-fiber nociceptors. Ongoing studies will determine the contribution of CB1 and CB2 receptors to the effects of WIN 55,212-2 on response properties of C-fiber nociceptors in tumor-bearing mice.

Title: Effects of analgesic agents, Neurotropin on neuronal cell

Authors: *R. ISONAKA[1], T. TAKENAMI[2], T. KATAKURA[1], T. KAWAKAMI[1]
[1]Physiol., [2]Anesthesiol., Kitasato Univ. Sch. of Med., Sagamihara, Japan

Abstract: Neurotropin® is one of analgesic agents, which is known to treat chronic pain such as lumbago, postherpetic neuralgia and fibromyalgia in the fields of orthopedics, neurology, and anesthesia and it is ordinarily used in Japan. The ingredient of this drug is a non-protein extract from inflamed skin of rabbits inoculated with vaccinia virus. Axonal transport is an important function to supply materials for maintenance of neuronal cells. In this study, we investigated the influence of neurotropin on axonal transport in cultured mouse dorsal root ganglion (DRG) neurons using video-enhanced microscopy. Neurotropin (0.0001-1 Neurotropin Unit (NU/ml)) decreased anterograde and retrograde movement of organelles in a time-and concentration-dependent manner. Neurons treated with neurotropin at any concentration were not morphologically different from those of the control neurons. Axonal transport in sensory neurons is closely related to alleviation of neuropathic pain, therefore these results suggest that the analgesic effect of neurotropin for neuropathic pain is caused by inhibition of axonal transport.

Title: *In vivo* imaging of spine dynamics in the barrel cortex during perceptual learning

Authors: *J. I. PARK[1], T. CELIKEL[2], A. W. MCGEE[3]
[1]Grad. Program in Neurobio., [2]Neurobiology, Biomed. Engin., USC, Los Angeles, CA; [3]Saban Res. Institute, Children's Hosp. Los Angeles, Keck Sch. of Medicine, Univ. of Southern California, Los Angeles, CA

Abstract: Understanding how sensory experience modifies neural circuits is central to understanding mechanisms of perceptual learning. Though novel sensory experience and improved motor performance modify functional synaptic connectivity in the cerebral cortex, the specificity and mechanisms of anatomical plasticity that contribute to sensory and motor learning are unclear. We are investigating this question by performing in vivo longitudinal multi-photon imaging of spine dynamics before, during, and after mice are trained on a perceptual learning task.

Our learning task, the gap-crossing task, is a whisker and barrel cortex-dependent object localization paradigm in which a mouse learns to locate a tactile object positioned with a variable distance while perched on an elevated platform. In the absence of visual cues mice locate the target using tactile cues; at distances larger than 5 cm tactile information is exclusively collected by rhythmic palpations of whiskers. However, not all whiskers contribute to tactile exploration on this task. Mice preferentially use C- and to a lesser extent D-row whiskers, while dorsally located A-row whiskers do not contribute to tactile exploration.

We take advantage of this preferential use of whiskers and the topographical nature of their representations in the barrel cortex to image spine dynamics in the apical dendrites of Layer 5 neurons in cortical domains corresponding to whiskers that contribute to gap-crossing performance (e.g. C2 whisker) as well whiskers not involved in the task (e.g. A2 whisker). After cranial window implantation which permits long-term, repetitive imaging, C2 and A2 whisker representations are mapped with intrinsic signal optical imaging. The dendritic spines within the C2 and A2 barrels are then imaged every four days using two-photon laser scanning microscopy. This is done over multiple intervals before beginning the task to determine baseline dynamics, as well as during and after training. This study will reveal anatomical changes associated with perceptual learning while providing within animal controls for the role of sensory experience in shaping anatomical dynamics in the network.

Title: Functional recovery from infraorbital nerve crush revealed by intracellular recordings from an *in vitro* preparation of neonatal rats

Authors: *F.-S. LO, R. S. ERZURUMLU
Anat & Neurobiol, Univ. Maryland Sch. Med., BALTIMORE, MD

Abstract: Neonatal infraorbital nerve (ION) transection in the rat leads to disappearance of whisker-specific neural patterns along the central trigeminal pathway. Physiological studies show that the complete whisker deafferentation results in conversion of functional synapses into silent synapses and a rapid reactive synaptogenesis in the trigeminal principal nucleus (PrV). Regeneration of the damaged ION fibers is a slow process and never complete. ION crush, on the other hand, leads to a partial blockade and a rapid recovery of ION function. We developed an in vitro trigeminal ganglion preparation in which trigeminal ganglion (TG) cells that innervate the whisker pad are morphologically intact. Intracellular recordings from those TG cells show that there are two classes of cells according to the shape and duration of the action potential (AP): S-type and F-type. S-type cells account for 77% and F-type cells, 23% of the recorded TG cells (n=26). Because TG cells that innervate whisker pad are widespread in the central part of the TG (Klein et al., 1986), we randomly impaled TG cells in the central TG and tested the response to stimulation of ION. Sixty nine percent of recorded TG cells (n=26) revealed an action potential with a fixed latency after ION stimulation indicating that they innervate the whisker pad. Immediately after ION crush, stimulation of ION distal to the crush site induced APs in only 25% recorded cells (n=20) that was significantly lower than the normal side (p&gt0.30). On post-crush day seven, 80% of recorded cells (n=20) responded to the stimulation of the distal ION, that was significantly higher than 3 days after crush (p<0.005), but did not differ from the normal side (p>0.40). These results indicate that function of the ION is partially blocked by crush and recovers in one week. In addition, the ratio of S- and F-type recorded TG cells after ION crush was about the same as normal side (p>0.70), suggesting that ION crush blocks ION fibers non-selectively.

Title: Adult plasticity in the rodent barrel cortex measured with voltage sensitive dye imaging

Authors: *C. A. GOLLNICK, D. C. MILLARD, A. D. ORTIZ, Q. WANG, R. V. BELLAMKONDA, G. B. STANLEY
Georiga Inst. of Technol., Atlanta, GA

Abstract: Neuroplasticity is the central mechanism the brain uses to recover from disease. Dramatic examples of plastic mechanisms can be observed in the developing brain; however, plastic changes in the adult brain are more subtle, limited and not well understood. In the rodent barrel cortex, the discrete barrel representations in layer 4 are stabilized early in life, while the supragranular layer circuitry remains sensitive to external stimuli. Here we use voltage-sensitive dye imaging to characterize plastic changes in layer 2/3 of the barrel cortex in anesthetized rats (>P60). A DE-paired whisker trimming paradigm is used to drive cortical reorganization. In control animals, the activation of a D-row whisker spreads symmetrically both towards the spared and deprived whisker rows. In contrast, the activation of D-row whisker in a DE-paired animal spreads asymmetrically and is biased towards the spared whisker row. Preliminary results suggest that this asymmetry occurs primarily because of a reduction of spread into deprived columns and not as a result of increased spread into spared columns. Additionally, the direction of the asymmetry can be controlled by flipping the spared and trimmed whisker rows. These results indicate that the cortical response to a whisker deflection remains sensitive to whisker trimming into adulthood, possibly reflecting the potential for whisker loss and regrowth throughout life.

Title: Reversible deactivation of motor cortex and posterior parietal cortex in macaques by cooling induces shifts in receptive field size and location in anterior parietal neurons

Authors: *A. B. GOLDRING[1,2], D. F. COOKE[1,2], C. B. WEATHERFORD[2], G. H. RECANZONE[3], S. I. SIMON[4], T. PAN[4], L. KRUBITZER[1,2]
[1]Psychology, [2]Ctr. for Neurosci., [3]Neurobiology, Physiol. and Behavior, [4]Biomed. Engin., Univ. of California, Davis, Davis, CA

Abstract: Feed-forward models of somatosensory processing posit that "high-order" somatosensory areas (such as Brodmann's area 2) construct their receptive fields via input from primary areas in anterior parietal cortex (such as 3b and 1), as well as some direct thalamic input. However, reciprocal connections between area 2 and areas within posterior parietal cortex (PPC) suggest that feedback also plays a role in determining the construction of somatosensory receptive fields. For example, focal aspiration lesions of the lateral-most extent of Brodmann's area 5 (area 5L) induce receptive field shifts in area 2 within 60 minutes (Padberg et al., 2010). To study this rapid plasticity more precisely, we used a cooling chip (Cooke et al., 2012) to reversibly deactivate cortex in an anesthetized macaque while mapping the hand and forelimb representations within areas 1 and 2. Cooling cortex to ~20 degrees C disrupts or abolishes local neural activity while neurons in surrounding tissue remain responsive. We cooled restricted portions of the forelimb representation in the lateral portion of the rostral bank of the intraparietal sulcus defined by Seelke et al. (2011) as area 5L. In separate runs, we also cooled portions of areas 7b and M1. Data were collected before cooling, while the cortex was cooled, and after rewarming. We characterized the receptive field properties of neurons in areas 1 or 2 via light cutaneous stimulation as well as hard taps, squeezes, and joint manipulation. Several locations both inside and outside the receptive fields were stimulated via computer-controlled air puffs in order to quantify the responses. Preliminary analysis suggests that deactivation of each region studied produced changes of receptive field boundaries for area 2 neurons. For example, a site within area 2 which was originally responsive to stimulation of proximal portions of dorsal digits 4 and 5 became responsive to stimulation of the entire dorsal surface of digits 3-5 during cooling of area 7b. Cooling of area 5 produced no such shifts within the same site, but cooling of M1 expanded the receptive field to include the entire dorsal surface of the hand. Subsequent

rewarming saw a return of receptive fields to their original extent.
These results imply that a strictly hierarchical model is insufficient to account for the structure of receptive fields within anterior parietal cortex. Additionally, these immediate shifts in receptive field structure provide insight into the immediate recovery period following a stroke or other forms of cortical injury.

Title: Disinhibition in L2/3 recurrent networks during whisker map plasticity

Authors: *Y. R. SHAO, J. CHUNG, D. E. FELDMAN
Mol. and Cell. Biol., UC Berkeley, Berkeley, CA

Abstract: Sensory experience drives robust cortical map plasticity, but significant components of its cellular and circuit basis remain unknown. In rat somatosensory cortex (S1), whisker deprivation drives depression of spiking responses in cortical layer (L) 2/3. This plasticity is known to involve a parallel reduction in excitation (E) and inhibition (I) in the feedforward L4-L2/3 projection (House 2011), as well as reduced connection rates between L2/3 pyramidal cell pairs (Cheetham 2007). How sensory deprivation affects overall recurrent network function (including E-I balance) has remained elusive, because of the inability to selectively activate recurrent networks using extracellular stimulation. To overcome this problem, we introduced channelrhodopsin-2 (ChR2) specifically to L2/3 pyramidal cells via in utero electroporation and used light to activate the L2/3 recurrent network in ex vivo across-row S1 slices at P17-24.
To specifically activate the L2/3 recurrent network in a single whisker-related column, we first identified light intensities that drove spiking of ChR2-expressing pyramidal cells only within the stimulated column. We measured recurrent synaptic responses in ChR2-negative pyramidal cells in voltage clamp (31C, with APV and saclofen in bath). A 2 ms light flash evoked recurrent excitation followed by inhibition 2-3 ms later. E-I balance varied with stimulus intensity, with little or no inhibition at minimal activation, preferential recruitment of inhibition as stimulus intensity was increased, and stable E-I ratio dominated by inhibition over a wide range of strong

intensities. We then deprived the D row of whiskers for 5-12 days from P12 to examine the effect of deprivation. Deprived D columns had modestly weaker recurrent excitation, but a major decrease in recurrent inhibition, compared to spared B columns. This resulted in a significant shift in E-I balance toward more excitation. Relative E-I timing was mostly preserved. Deprivation-induced changes were not observed in neighboring spared C and E columns. Thus, the recurrent L2/3 network responds to deprivation with a preferential weakening of inhibition, in contrast to preserved E-I balance in the feedforward L4-L2/3 pathway. Preferential weakening of recurrent inhibition will compensate for decreased sensory drive, suggesting that L2/3 recurrent circuits are a major locus of homeostatic plasticity. In addition, reduced recurrent inhibition may gate or promote subsequent components of sensory map plasticity.

Title: Cholinergic-mediated increasing spiking response in barrel cortex layer V pyramidal neurons

Authors: *A. NUNEZ[1], S. DOMINGUEZ[2], W. BUÑO[2], D. FERNANDEZ DE SEVILLA[3]
[1]Univ. Autonoma De Madrid, Madrid, Spain; [2]Inst. Cajal, CSIC, Madrid, Spain; [3]Anatomia, Histologia y Neurociencia, Univ. Autonoma de Madrid, Madrid, Spain

Abstract: Neocortical cholinergic activity plays a fundamental role in sensory processing and cognitive functions, but the underlying cellular mechanisms are largely unknown. We analyzed *in vitro* in rat "barrel cortex" $L5_A$ pyramidal neurons the effects of acetylcholine (ACh) on synaptic transmission and cell excitability. ACh through nicotinic and M1 muscarinic receptors enhanced excitatory postsynaptic currents and through nicotinic and M2 muscarinic receptors reduced inhibitory postsynaptic currents. These ACh-induced changes resulted in the generation

of slow all-or-none Ca^{2+} spikes and action potential bursts evoked by electrical stimulation of basal dendrites at $L5_B$. Ca^{2+} spikes were mediated by activation of NMDA receptors and L-type voltage-gated Ca^{2+} channels. Essentially identical effects were observed in the absence of activation of ACh when $GABA_A$–mediated inhibition was blocked by PiTX. Additionally we demonstrate *in vivo* that basal forebrain stimulation induced an atropine-sensitive increase of Layer 5 action potential responses evoked by *vibrissa* deflection; an effect mainly due to the enhancement of a NMDAR component. Therefore, ACh modified the excitatory/inhibitory balance and switched L5 pyramidal neurons to a bursting mode that caused a potent and sustained response enhancement with possible fundamental consequences in the signal processing capacity and plastic properties of the barrel cortex.

Title: Plasticity-related genes expression is modified by sensory stimulation in the adult mouse barrel cortex.

Authors: *C. SAVARY[1], N. WENGER[1], F. OLIVERI[2], H. FIUMELLI[3], J.-L. MARTIN[3], U. ALBRECHT[4], M. A. RÜEGG[2], E. WELKER[1]

Abstract: Sensory information helps to shape neuronal circuits during development and adulthood. In the mouse barrel cortex, cells from layer IV are able to adapt their functional state to an increased flow of sensory information from the mystacial whiskers. Previous studies in our group have shown that whisker stimulation induced the formation of inhibitory synapses in the corresponding barrel (Knott et al., Neuron 34: 265-273, 2002) and decreased neuronal responses toward the deflection of the stimulated whisker (Quairiaux et al., J.Neurophysiol. 97: 2130-2147,

2007). Together these observations have turned the barrel cortex into a model to study homeostatic plasticity.
At the cellular level, neuronal activity triggers intracellular signalling cascades leading to a transcriptional response. Experience-dependent gene expression acts then to both modulate gene expression and to directly modify neuronal physiology and morphology. To further characterize the molecular pathways involved in the synaptic changes after whisker stimulation, microarray analysis on laser-dissected barrels in sections through layer IV revealed an upregulation of a series of genes in the stimulated barrels. We then focused on the following plasticity-related genes: the transcription factors, neuronal PAS domain protein 4 (NPAS4) and neuronal activity-regulated pentraxin (NARP); the cytoskeleton protein, cardiac troponin C (TNNC1); and the pituitary adenylate cyclase-activating polypeptide (PACAP).
In this study, adult males from the C57Bl/6J strain had their left C1, C2, C3 whiskers stimulated. For each gene of interest, in situ hybridization and immunohistochemistry revealed different patterns of mRNA and protein expression in the stimulated barrels. NPAS4 and NARP show an increase for both mRNA and protein in the stimulated barrels. The increased level of PACAP immunoreactivity is localized in layers II/III and V of the cerebral cortex, whereas there is no difference of immunostaining inside the stimulated barrels compared to the non-stimulated ones. However, in situ hybridization indicates increased PACAP mRNA expression in the stimulated barrels. Finally, the increase of TNNC1 mRNA and protein is localized in neurons positioned at the interface between layers IV and V.
Altogether, these data confirm the results from the microarray analysis and they suggest a differential role of the tested genes in the structural and physiological reorganization observed after whisker stimulation.

Title: Phantom pain is associated with preserved local activity but disturbed functional connectivity

Authors: *T. R. MAKIN[1], J. SCHOLZ[1,2], N. FILIPPINI[1], D. HENDERSON SLATER[3], I. TRACEY[1], H. JOHANSEN-BERG[1]
[1]Univ. of Oxford, Oxford, United Kingdom; [2]The Hosp. for Sick Children, Toronto, ON, Canada; [3]Nuffield Orthopaedic Ctr., Oxford, United Kingdom

Abstract: Phantom pain has become an influential example of maladaptive cortical plasticity. According to this model, sensory deprivation following limb amputation allows for intra-regional invasion of neighbouring cortical representations into the former hand area of the primary sensorimotor cortex, which gives rise to pain sensations. Over the years, this model was extended to explain other disorders of pain, motor control and tinnitus, and has inspired rehabilitation strategies. Yet, other research, demonstrating that phantom hand representation is maintained in the sensorimotor system, and that phantom pain can be triggered by bottom-up aberrant inputs, may call this model to question. Using fMRI, we identified the cortical area representing the missing hand in a group of 18 arm amputees (Fig. 1A, bottom image and 1B). This allowed us to directly study changes in the "phantom" cortex associated with chronic phantom pain, using functional connectivity (Fig. 1D) and voxel-based morphometry (Fig. 1C). We show that, while loss of sensory input is generally characterized by structural degeneration of the deprived sensorimotor cortex (Fig 1C, top), the experience of persistent pain was associated with preserved intra-regional structure and functional organization (Fig 1B and 1C, bottom panels, respectively). Furthermore, consistent with the dissociative nature of phantom sensations from other sensory experiences, phantom pain is also associated with reduced long-range inter-regional functional connectivity (Fig 1D, bottom panel). We propose that this disrupted inter-regional connectivity may be consequential, rather than causal, of the retained yet isolated local representation of phantom pain. We therefore propose that, contrary to the maladaptive model, cortical plasticity occurs when powerful and long-lasting subjective sensory experience, most likely due to peripheral inputs, is decoupled from the external sensory environment.

Title: Breaking the boundaries of somatosensory plasticity: Improved touch at the fingers transfers to the lips.

Authors: D.-A. MURET[1], H. R. DINSE[2], C. URQUIZAR[1], O. SILLAN[1], K. REILLY[1], *A. FARNE[1]
[1]ImpAct Team, INSERM 1028, CNRS 5292, Ucbl1, Bron, France; [2]Neural Plasticity Laboratory, Inst. für Neuroinformatik, Ruhr-Universität Bochum, Bochum, Germany

Abstract: It is now well established that cortical plasticity occurs in the adult brain and that plastic phenomena are involved in many brain functions. Understanding the rules governing plasticity and its functional consequences is extremely challenging. A cutaneous coactivation (CA) protocol has been successfully used to study somatosensory plasticity (see Godde et al, 2003). CA relies on the Hebbian postulate and consists of synchronous and passive coactivation of several non-overlapping receptive fields which produces transient somatosensory changes. The aim of this study was to evaluate whether pure somatosensory plasticity, experimentally induced at a specific cutaneous location (i.e., right index fingertip) can cross somatotopically defined boundaries and functionally affect physically distant, but cortically adjacent body-part regions (i.e., the perioral lip region). A two-point discrimination (2PD) task was used to determine the spatial discrimination thresholds at the right and left index finger (RD2 & LD2), and at the right and left sides of the upper lip area. This test was performed during 4 sessions on 2 consecutive days. Between the third and fourth session, a vibrotactile CA was applied for three hours at the RD2 fingertip. Thirty participants were randomly attributed to either of two groups: a test group (n=15, mean age = 20.53 ± 2.26 years), in which subjects received a true CA at the RD2 fingertip; and a control group (n=15, mean age = 23.5 ± 3.25 years), in which the CA was replaced by a sham CA (stimulator fixed at the fingertip but turned off). Results showed that in

the test group three hours of CA led to a significant decrease of the 2PD threshold at RD2 fingertip, from 1.77 ± 0.28 mm to 1.52 ± 0.43 mm (mean decrease of 15.26%), thus replicating previous results. Critically, a significant 2PD threshold decrease was also found at both sides of the upper lip area (from 6.02 ± 0.88 mm to 5.44 ± 1.24 mm, mean decrease of 10.29%). No effects were found at either the LD2 fingertip or at any body-part region of the control group. These results demonstrate that experimentally-induced plasticity following RD2 coactivation improves participants' tactile discrimination performance not only at the coactivated body site, but also at cortically adjacent body sites. Thus, CA-induced somatosensory plasticity appears to cross somatotopically defined boundaries between cortical body-parts representations, spreading its functional consequences to cortically adjacent, but peripherally unstimulated body parts.

Title: Factors influencing the sparse sensory code in L2/3 of mouse somatosensory cortex

Authors: *K. CLANCY, J. ELSTROTT, T. MIYASHITA, D. FELDMAN
UC Berkeley, Berkeley, CA

Abstract: Much of rodent neocortex exhibits sparse spiking activity in which only a fraction of neurons are active at one time. In primary sensory cortex, stimulus selectivity is one major cause of sparse firing, but other factors may also contribute, including cell type, brain state and the potential existence of intrinsically high- and low-responsive subcircuits (Wolfe 2010). In primary somatosensory cortex (S1), layer 2/3 (L2/3) has the lowest response probability, and most spiking activity is from a small subpopulation (~ 20%) of more active neurons. Here we examine the factors that determine response probability within the sparsely active L2/3 network.
We performed ensemble 2-photon Ca^{2+} imaging using bulk loaded OGB-1AM in L2/3 of mouse S1 and used the fast-oopsi algorithm (Vogelstein 2010) to detect spikes from ΔF/F traces. Spontaneous and whisker evoked activity were imaged in P23-P45 mice anesthetized with urethane/chlorprothixene. Neurons displayed a range of spontaneous firing rates and response probabilities, however there was a significant correlation ($R^2 = 0.58$) between whisker-evoked

response probability, termed p(r), and spontaneous activity, suggesting that high p(r) neurons may be embedded in a specialized, more active subnetwork. Low p(r) neurons were more narrowly tuned to their preferred whisker. Cells were more likely to respond to a whisker stimulus when the cortex was in a LFP 'down' state. In contrast, spontaneous spikes were more likely to occur when the cortex was in an 'up' state. High p(r) neurons were not exclusively interneurons, as seen in recordings in GAD67-GFP and PV-tdTomato transgenic mice.
The sparse code was plastic in response to whisker deprivation. Animals that underwent 3 days of D-row whisker deprivation beginning at P23-P33 showed a reduced proportion of high p(r) neurons compared to control animals. The spontaneous firing rate and breadth of whisker tuning appeared unaffected. This suggests that the high p(r) neurons are more involved in expression of rapid deprivation-induced plasticity. Together, these results indicate that a population of special, high p(r) neurons exists that are preferentially represented in network activity, and are a locus for rapid experience-dependent plasticity.

Title: Modulation of sensory cortex excitability is dependent on the intensity of peripheral electrical stimulation

Authors: *P. W. HODGES, L. CHIPCHASE, L. SMITH, A. MATUS, S. SCHABRUN
CCRE SPINE, Univ. Queensland, Brisbane, Australia

Abstract: Background: Peripheral electrical stimulation (PES) is commonly applied at sensory intensities in rehabilitation for treatment of pain and at motor intensities to facilitate muscle contraction. These stimuli have opposite effects on excitability of corticomotor pathway: excitability is increased by motor stimulation and reduced by sensory stimulation. It is unknown how the intensity of stimulation affects sensory cortex activity. Methods: Thirteen healthy individuals attended two experimental sessions at least 48 hours apart. Participants received 30 minutes of PES to right abductor pollicis brevis (APB) at: i) sensory intensity (perceptual

threshold), or ii) motor intensity sufficient to induce a muscle contraction. Order of interventions was randomised across participants. Excitability of the corticomotor pathway was measured using transcranial magnetic stimulation (TMS) and activity of the primary sensory cortex using somatosensory evoked potentials (SEPs) before and after each intervention. M-waves were recorded to evaluate changes in the muscle/neuromuscular junction. Results: The amplitude of the N20-P25-N33 complex of SEP, representative of processing in the primary sensory cortex, was increased with stimulation at motor intensity, and decreased with sensory stimulation. Similarly, the amplitude of the motor response evoked by TMS was augmented following motor stimulation and diminished following sensory stimulation. There was no change in the peripheral apparatus with either PES protocol. Conclusion: Altered activity in the primary sensory cortex mirrors that occurring in corticomotor pathways following PES at motor and sensory intensities. This finding suggests co-modulation of changes in primary sensory and motor regions. Transmission of information via cortico-cortical circuits may provide a candidate mechanism for how afferent information in the form of PES alters corticomotor pathway excitability.

Title: Tactile stimulation increases the neuronal caudal ambiguous nucleus development of perinatally underfed pups

Authors: D. LOPEZ, C. TORRERO, M. REGALADO, *M. A. SALAS
Developmental Neurobio. and Neurophysiol., UNAM, Queretaro, Mexico

Abstract: Undernutrition is a health problem that produces brain morphological alterations and cognitive deficiencies in children of underdeveloped countries. Nutritional rehabilitation could be potentiated by different concurrent therapy techniques. Touch is a modality of sensory system first developed during the fetal and neonatal stages that may be affected by perinatal undernutrition in rats interfering with crying and ultrasound vocalization (USV) emissions. The caudal ambiguous nucleus (AMBc) neurons innervate the pharynx modulating the motor activities underlying USV. The current study analyses the effects of tactile stimulation (TS) on

the AMBc neuronal (Golgi-Cox) development of perinatally underfed rats at 8, 12, and 15 PND. Undernutrition includes the pregnant food intake reduction, followed by the rotation (12h) of a nipple-ligated and a normal dam between litters. The dendritic tree and soma measurements of multipolar neurons in control (C), underfed (U), control stimulated (CS) and underfed stimulated (US) groups were measured. Delicate TS (body massage and passive limb movements) was applied (15 min) daily (days 4-15 of age). In the U subjects multipolar neuronal dendritic scores were reduced ($p<0.05$) in both the number and density at 8 and 15 PND. By contrast TS increases the values of these parameters along the same days of the study ($p<0.05$). Concerning the soma parameters of multipolar neurons, they were reduced in the U subjects, with increments in the perimeter and area of the stimulated groups (CE, US). Additionally, body weight of U animals were consistently reduced; although the stimulated subjects (CE and UE) were increased compared to C and U pups. Data suggest that TS through the increased somatosensory ascending neuronal activity, and the possible release of growth factors, may have an important role to modulate the AMBc neuronal discharges to the pharyngeal motor activity interfering with the USV emissions and the mother-litter interactions at critical stages of life.

Title: Two dimensional changes in the body model for the hand following the brief use of a hand-like tool

Authors: *L. MILLER[1,2], M. R. LONGO[3], A. P. SAYGIN[1,2]
[1]UCSD, La Jolla, CA; [2]Kavli Inst. for Brain and Mind, La Jolla, CA; [3]Birkbeck, Univ. of London, London, United Kingdom

Abstract: Tool use is a ubiquitous and crucial aspect of human life. It is well known that neural representations of the body in somatosensory and parietal cortices reorganize following long-term changes to the body. We sought to explore effects of brief periods of tool use on dimensional representations of the body called the body model. Recently it has been shown that the use of a long, grabber-like tool leads to a systematic mislocalization of touch along the user's arm (Cardinali et al., 2009, Current Biology), suggesting that the tool became incorporated into

the body model and lead to an elongation of the arm representation in one dimension. Here, we sought to characterize two-dimensional changes to the body model following the use of a custom hand-shaped tool measuring approximately 21 by 45 centimeters. This novel tool was strapped to user's arm, and included five dynamic plastic fingers that moved concurrently with movements of the subject's own fingers. To measure plastic changes to the body model, we used a tactile distance judgment paradigm (de Vignemont, et al. 2005, Current Biology). Wooden points at variable distances (20 mm, 30 mm, 40 mm) were used to touch an experimental site (the dorsum of the hand) and a control site (the forehead). Subjects were then asked to report which touch had the greatest distance between the two points. This procedure was performed before tool use, and repeated after an 8-minute period of tool use (involving grasping, lifting and placing a set of objects into containers). Touches were oriented either horizontally (i.e., *across* the hand or forehead) or vertically (i.e., *along* the hand or forehead). We hypothesized that following tool use, subjects would report that touches to the hand felt larger than to the control site. For horizontal/across touches, the results confirmed our hypothesis, revealing a significant increase consistent with the widening of the hand after tool use. This effect was replicated with the forearm as the control site. Vertical touches however revealed the opposite pattern. Thus we show that the brief use of a hand-like tool can lead to changes in the body model of the hand in two dimensions, and that there may be an interaction between changes in the horizontal and vertical directions. We will use fMRI to determine whether this plasticity is reflected in changes in somatosensory cortex, or in representations of the body in the parietal cortex.

Title: Long-distance plasticity. I. Evidence of functional and behavioral correlates of abnormal bundles in callosal dysgenesis.

Authors: *M. C. MONTEIRO[1,2,3], V. LAZAREV[2], R. DEOLIVEIRA-SOUZA[1], L. DEAZEVEDO[2], J. MOLL[1,4], R. LENT[3,4], F. TOVAR-MOLL[1,3,4]
[1]D'Or Inst. for Res. and Educ. (IDOR), Rio De Janeiro, Brazil; [2]Fernandes Figueira Institute, FIOCRUZ, Rio de Janeiro, Brazil; [3]Federal Univ. of Rio de Janeiro, Rio de Janeiro, Brazil; [4]Natl. Inst. for Translational Neurosci. INNT, São Paulo, Brazil

Abstract: Long-distance plasticity is the anomalous formation or redirection of fiber tracts in the brain, after major disturbances of developmental events. It occurs in callosal dysgenesis (CD), a morphogenetic failure of the corpus callosum (CC), without the split-brain syndrome. Previous studies demonstrated abnormal white matter pathways in CD. To address the functional correlates of some of these bundles, we combined diffusion tensor imaging (DTI) with quantitative electroencephalography, and neuropsychological assessment of interhemispheric information transfer.
Volumetric anatomical (3DT1) and DTI (2,5mm isotropic voxel) images were acquired (3T, Achieva Philips) from 5 patients and 7 healthy volunteers. Neurophysiological assessment was done in these same patients and 15 controls by 16-channel eletroencephalogram recording (Biologic) and analysis of coefficients of coherence (CChr) in 5 frequency bands (Brainsys). Neuropsychological evaluation consisted of tactile recognition and naming tasks and was applied in all acallosals and 12 age-matched normal-IQ volunteers. Groups were compared by Mann-Whitney's (neurophysiology and neuropsychology) and *t test* (neuroimaging).
In patients, structural images showed: partial (n=2) and hypoplasic (n=1) callosal dysgenesis, and agenesis (n=2). DTI and tractography confirmed bilateral Probst bundles (PB) connecting intrahemispheric cortical regions in all patients, and Sigmoid bundles (SB) connecting frontal with contralateral occipitoparietal cortices in partial callosal dysgenesis. The CChr showed increased intrahemispheric and decreased interhemispheric coherence in CD. However, in partial dyscallosals, higher interhemispheric coherence in the frontal area was observed; likewise, higher contralateral coherence between anterior and centroparietooccipital (particularly right-to-left) areas was observed. No impairment was found in tactile object recognition and naming in acallosals. However, they showed a bilateral impairment in transfer of tactile spatial cognition. Changes in electrophysiological connectivity in CD may be the functional counterpart of anomalous bundles resulting from long-distance plasticity, while increased intrahemispheric coherence in CD patients may be attributed to the PB, while anatomical connectivity of SB may underlie the interhemispheric coherence observed between contralateral anterior and posterior cortical areas. Although dyscallosals lack a complete disconnection syndrome, compensatory plasticity seems to have limits, since a behavioral impairment is found, not attributable to cognitive or other cerebral impairment.

Title: Normal DISC1 function is required during a neonatal critical period for development of adult plasticity

Authors: *S. GREENHILL, K. FOX
Dept. of Biosci., Cardiff Univ., Cardiff, United Kingdom

Abstract: Disrupted in Schizophrenia-1 (DISC1) is the subject of intensive investigation since its dysfunction has been associated with increased likelihood of schizophrenia in humans. Induced malfunction of the DISC1 pathway at P7 produces schizophrenia-like behaviour in adult mice (Li et al, 2007). We have previously demonstrated that the short-term activation of a dominant negative fragment of the DISC1 c-terminal (DISC1-cc) at postnatal day 7 leads to deficits in experience-dependent plasticity in the barrel cortex of adult mice (Juczewski et al, SfN 2010). This would suggest that the activation of DISC1-cc affects neuronal function during a critical period of development. Here, we aimed to further elucidate the period in which juvenile DISC1 disruption leads to deficits in adult experience-dependent plasticity.
DISC1-cc transgenic mouse pups (and wild-type littermates) were injected with tamoxifen (20ug/g body weight in corn oil, subcutaneous) in three groups, each corresponding to a different timepoint of DISC1-cc activation (P7, P11-13 and P28). Tamoxifen injection releases the dominant negative fragment of DISC1 (671-852aa) from a mutant estrogen receptor ligand binding domain (LBD) for approximately 24-48 hours (Li et al, 2007). Pups were allowed to develop until P50 and were then subjected to deprivation of all but the D1 whisker for a period of 18 days, followed by 7-10 days of whisker re-growth. This protocol is normally sufficient to induce strong changes in the receptive field of neurons in barrels surrounding the spared whisker's barrel (Glazewski et al, 1996).
After the deprivation and re-growth period, single unit recordings (n=30 animals) were performed in vivo to measure the receptive fields of neurons in barrels surrounding the D1 barrel. Deprived mutant groups at different timepoints were compared with a one-way ANOVA which found a highly significant effect of injection day ($P<0.0001$, $F=32.1$, $df=2,16$). Post-hoc t-tests revealed that activation of DISC1-cc at P7 completely abolished the response to deprivation, activation at P28 did not inhibit plasticity in adult animals, and activation between

P11 and P13 produced a moderate inhibition of adult somatosensory plasticity. These results suggest a novel critical period of adult plasticity in the barrel cortex, which closes during the second postnatal week.

Title: Transient neonatal impairment of DISC1 function delays dendritic and synaptic development of cortical layer III neurons

Authors: *N. R. HARDINGHAM, S. D. GREENHILL, K. FOX
Cardiff Univ., Cardiff, United Kingdom

Abstract: DISC1 has been implicated in schizophrenia and has an important role in brain development. We used a transgenic mouse with a dominant negative fragment of the DISC1 c-terminal (DISC1-cc), activated for 24-48 hours by injection of tamoxifen. Activation of the mutant protein at P7 results in schizophrenic like behaviour (Li *et al*, 2007) and a loss of experience dependent plasticity in layer 2/3 of adult barrel cortex, while activation of DISC1-cc at P28 has no effect on plasticity (Greenhill and Fox, SfN 2012). This suggests that a developmental process taking place between P7 and P28 is affected by the transgene.
To test how structural and synaptic development in the supragranular cortex were affected in the DISC1-cc mutant, we activated DISC1-cc at P7 and made whole cell recordings from layer 3 cells at P8, P14, P21 and P28. Wild type littermates were also injected with tamoxifen for comparison with the mutants. Electrical and synaptic properties of the neurons were recorded at the different ages whilst they were being injected with biocytin and/or Alexa 594 enabling subsequent morphological characterisation of the neurons. We also recorded mEPSPs and tested for LTP in the different experimental groups to measure synaptic efficacy and ability to undergo synaptic plasticity at different developmental stages.
Dendrites were immature at P8 (mean sholl count of 20 ± 2) and in wild types the dendritic growth largely took place between P8 and P14 (P14 mean sholl count of 52 ± 3; P28 mean sholl

count of 58 ± 3). However, in the DISC1-cc mutants, dendritic development was substantially retarded compared to wild types (DISC1-cc: P8 mean sholl count of 20 ± 2 ($p>0.05$ compared to wild types, df=28); P14 mean sholl count of 39 ± 4 ($p<0.05$ compared to wild types, df=31) while a normal developmental stage was reached by P21 (DISC1-cc, P21 mean sholl count of 55 ± 4, P21 mean wild type sholl count of 51 ± 8, $p>0.05$ comparison, df=20). It was found that dendritic growth in horizontal directions, into adjacent barrels was also substantially retarded in the DISC1-cc mutants at P14. Furthermore, the normal development of short term plasticity between P8 and P28 was disrupted in the mutants; in wild types the main reduction in paired-pulse depression took place between P8 and P14; in the mutants this change did not take place until between P14 and P21.
Thus it would seem that normal development of the supragranular barrel cortex is substantially retarded in the DISC1 mouse over the critical period of development and these structural and functional affects have a long-lasting effect on plasticity in the adult brain.

Title: Long-distance plasticity. II. Morphological evidence of novel abnormal bundles with possible compensatory functions in human callosal dysgenesis.

Authors: *R. V. BARBOSA[1], T. F. MARINS[1,2], N. D. A. QUEIROZ[1,2], I. BRAMATI[1,2], J. MOLL[2,3], F. TOVAR-MOLL[1,2,3], R. LENT[1,3]

Abstract: Long-distance plasticity is the anomalous formation or redirection of fiber tracts in the brain, after major disturbances of developmental events. It occurs in callosal dysgenesis (CD), a morphogenetic failure of the corpus callosum (CC) lacking the split-brain syndrome. Two major abnormal tracts in CD subjects have been previously described: the Probst bundle (PB), with a longitudinal course parallel to the midline and the lateral ventricle, and the Sigmoid bundle (SB), an asymmetric tract connecting the frontal lobe to the contralateral occipito-parietal cortex. Since patients with CD do not show the split-brain syndrome, we can expect them to have some kind of inter-hemispheric connection that somehow compensates the connectivity lost by lack of the CC. a hypothesis hardly attributable to these abnormal tracts.
The aim of this study was to look for other white matter changes in patients with CD by using diffusion tensor imaging (DTI) and tractography. Volumetric anatomical (3DT1) and DTI (2.5mm isotropic voxel) images were acquired (3T, Achieva Philips) from 6 patients and 6 healthy volunteers. Regions of interest (ROI) were selected at different parts of cingulum bundle (CB), corticospinal tract and posterior commissure (PC).These bundles were reconstructed by tractography, and values of fractional anisotropy (FA) were extracted. Values of FA of both groups were compared by Mann-Whitney's test.
In patients, structural images showed partial (n=2) and hypoplasic (n=2) callosal dysgenesis, and agenesis (n=2). DTI and tractography confirmed a bilateral PB in all patients, and a SB in dyscallosal but not acallosal subjects. We also found an increase of FA values in the CB of all patients. No difference was found regarding the corticospinal tracts. Surprisingly, tractography of the PC revealed a so far unknown abnormal interhemispheric bundle connecting bilaterally the parietal cortex of 4 patients through this midbrain commissure. This abnormal tract extended from dorsolateral cortical areas along the internal capsule and cerebral peduncle, to cross the midline and ascend with a symmetrical topography towards the homotopic sector of the contralateral cortex.
These results suggest that the early impairment of callosal development in CD subjects causes not only an impact on the morphology of intrahemispheric bundles, but also the formation of abnormal, so far unknown, interhemispheric pathways. It is conceivable that these symmetric connections be associated to the absence of a split-brain syndrome in CD, having a compensatory, rather than pathogenic function in these patients.

Title: The cuneate nucleus (CN) may not play a major role in delayed large-scale cortical reorganization in rat forepaw barrel subfield (FBS) cortex

Authors: *R. S. WATERS, C.-X. LI, S. VEMULAPALLI
Dept. of Anat. and Neurobio., Univ. Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: Introduction: We previously reported that delayed large-scale cortical reorganization in the forepaw barrel subfield (FBS) cortex requires 3 or more weeks before cells in the deafferented cortex begin responding to new input from the shoulder and trunk. At 6 weeks post deafferentation, the majority of sites in the FBS are responsive to the new input. Since new input was shown not to originate from adjacent cortex, we proposed that it must derive from subcortical circuits. In the present study, we examined receptive field input to neurons in the cuneate nucleus (CN) between 1 and 11 weeks following forelimb amputation and report little evidence for CN being a major substrate for large-scale cortical reorganization.
Methodology: Rats (6-8 wks of age) anesthetized with Nembutal received unilateral forelimb amputation. At 1 to 11 wks post-amputation, CN was physiologically mapped using multiunit recording. Rats were anesthetized with Ketamine/Xylazine (100 mg/kg), CN was exposed and an electrode was inserted to a depth of 100 microns, advanced in 50 or 100-micron steps to a depth of 900 microns, and receptive fields were recorded at each step. Lesions were made to mark recording sites, animals were perfused, brains were removed and sectioned, tissue was stained with cytochrome oxidase (CO) and electrode penetrations were reconstructed. Detailed mapping was carried out in CN in the obex region. For analysis, CN was divided into medial and lateral agranular zones, and a central CO-rich cluster zone.
Results: (a) CN, in the vicinity of obex, contains a central barrel region and surrounding agranular regions. (b) The central barrel region is unresponsive to receptive field input during the first week following amputation. (c) At weeks 2 and 3, approximately 22% of the sites respond to new input from trunk and shoulder. (d) After week 3, the central region becomes largely unresponsive again. (e) In contrast, new input is found in the agranular regions as early as post amputation week 2 and continues throughout week 11.
Interpretation: We hypothesized that the CN central barrel-like region would reorganize prior to reorganization in the FBS. The modest reorganization observed during weeks 2 and 3 is unlikely to form the hypothesized substrate for delayed large-scale cortical reorganization.

Title: Changes in cortical connectivity underlie altered sensory discrimination after stroke

Authors: *A. L. BORSTAD[1], S. CHOI[2], P. SCHMALBROCK[2], D. NICHOLS-LARSEN[3]
[1]Sch. of Allied Med. Professions, [2]Radiology, [3]Hlth. and Rehabil. Sci., The Ohio State Univ., Columbus, OH

Abstract: Background: Sensory discrimination is an important yet frequently overlooked aspect of human hand function. Following stroke discrimination impairment is common. Functional imaging studies suggest a bilateral network of brain areas support sensory discrimination. The purpose of this study was to quantify white matter connectivity in the right hand sensory discrimination network in stroke and control participants using diffusion imaging. We hypothesized that impaired interhemisphereic connectivity would correlate with sensory discrimination. Subjects and methods: Sensory function was evaluated, using monofilaments and the Hand Active Sensation Test (HASTe). Thiry-two direction diffusion MRI scans were obtained for 19 individuals with stroke (mean age=62.8 years), (9 right hemisphere) and 16 controls (mean age 59.2 years). Diffusion parameters were used to quantify connectivity of four white matter tracts that support sensory function. Data were analyzed using Oxford Centre for Functional MRI of the Brain Software Library (FSL). Results: Stroke participants had poorer sensory discrimination than controls (p=0.04). Touch perception was not statistically different between groups. Mean diffusivity was statistically higher for the stroke group than control participants for all four tracts measured. Left (L) thalamus to primary sensory (S1) (p<0.001), S1 to S1 interhemisphereic (p=<0.005), L S1 to L middle frontal (p=0.003), L S1 to L S2 (p=0.014). A negative linear relationship was identified between touch perception and thalamocortical connectivity (R= -.37, p=0.03) and between sensory discrimination and S1 interhemisphereic connectivity (R= -.42, p=0.02). In a multivariate regression 28% of sensory discrimination score can be predicted based on connectivity in the networks studied. Conclusions: Right sensory discrimination was poorer in stroke participants and connectivity was diminished in all tracts measured. Interhemisphereic connectivity was most closely correlated to sensory discrimination ability and may reflect the bilateral nature of this task.

Title: S1 somatotopy in adult rats and macaques is not pkmζ dependent

Authors: *J. C. IORDANOU, L. VON KRAUS, A. TARIGOPPULA, J. FERBINTEANU, J. T. FRANCIS
SUNY Downstate, Brooklyn, NY

Abstract: Zeta Inhibitory Peptide (ZIP), a pseudosubstrate for protein kinase mζ has been shown to abolish long-term potentiation in vitro and in-vivo and has been shown to decrease performance of learned tasks. ZIP has also been proposed as a possible treatment for focal hand dystonia and chronic pain; however the effects of intracortical ZIP infusions in sensorimotor cortex of normal untrained animals have not been examined. In this study we examined the effect of intracortical ZIP injections in the somatosensory cortex of naive rats (n = 7) and a Macaque. The subjects were implanted with arrays of electrodes in the primary somatosensory cortex, specifically in areas which showed clear response to tactile stimulation of the fingers. Additionally cannulas (1 in the rat, 3 in the macaque) were implanted to allow for direct ZIP injections into the region of cortex being recorded from. Subsequently the rats (Anesthetized) and macaque (Awake) received repeated tactile stimulation on the hand and fingers using a force-sensitive thwacker. Cortical responses to stimulation were recorded before (baseline) and after a 1.0μl infusion of either ZIP (10nmol/ml), scrambled ZIP(10nmol/ml), or vehicle was administered through each cannula. To assess ZIP effects at its maximum (2 hours after infusion) tactile stimulations with recordings resumed in rats at intervals of 20 minutes up to 3 hours post-infusion. In the macaque, one recording session was performed approximately 2 hours post-infusion. The neural recordings were examined for changes in receptive field size and strength, stimulus field size and strength, as well as mutual information between neurons. To assess motor coordination, some of the rats were tested using a rotorod, grid walking test, and paw placement test. No significant differences were found between ZIP and control infusions (scrambled ZIP or vehicle) on either physiological or behavioral measurements. Thus the data suggest that maintenance of the size and strength of the somatotopic representation is not dependent on LTP processes involving PKMzeta.

Title: Ipsilateral responses and interhemispheric interactions in area 3b after dorsal column spinal cord injury in New World monkeys

Authors: *J. L. REED, H.-X. QI, J. H. KAAS
Psychology, Vanderbilt Univ., NASHVILLE, TN

Abstract: Lesions of the spinal cord dorsal columns (DC) produce permanent loss of afferents, depriving cortex of sensory input. We evaluated primary somatosensory cortex (area 3b) in New World owl monkeys and squirrel monkeys 5-9 weeks after incomplete unilateral cervical DC lesions. Over the first month after injury, area 3b reactivates and hand use improves; thus, we expected 3b neurons of deprived monkeys to recover nearly normal response properties. Neurons in the 3b hand representation do not typically respond to ipsilateral stimulation, but simultaneous tactile stimulation of both hands tends to suppress activity in 3b (Tommerdahl et al. 2006; Reed et al. 2011), and loss of input from a digit can reveal interhemispheric interactions (Calford and Tweedale 1990); thus, we investigated how DC lesions affected interhemispheric interactions in area 3b. We implanted a 100-electrode array in the 3b hand representation of normal monkeys and monkeys several weeks after lesions, then delivered tactile stimulation to both hands to examine intra- and inter-hemispheric modulation. We compared responses from 4 normal monkeys and 3 deprived monkeys and tested ipsilateral responses and interhemispheric interactions in 1 of the deprived monkeys, compared with results from such tests in 2 normal monkeys (Reed et al. 2011). We have not encountered responses to ipsilateral hand stimulation in normal 3b neurons; but in a monkey after DC lesion, 10.5% (6/57) of neurons showed significant firing rate increases in response to stimulation of the ipsilateral hand, while 61% (36/59) responded to stimulation of the contralateral hand on digits that mirrored those tested on the ipsilateral hand. Latencies of ipsilateral responses (mean = 29 ms) were similar to latencies of

contralateral responses in monkeys after DC lesions (31 ms; N = 3 monkeys); and ipsilateral response magnitudes (mean = 16 spikes/s) were similar to contralateral response magnitudes in deprived and normal monkeys (17 spikes/s). When both hands were stimulated simultaneously, 63% (44/70) of units showed no significant difference in response magnitude compared to that of the contralateral stimulation alone, 23% (16/70) were suppressed, and 14% (10/70) were facilitated. These findings may indicate that facilitative interactions occur more often in cortex reactivated after DC lesions than in normal cortex as reported in previous studies. Results from neurons responding to ipsilateral hand stimulation after unilateral DC lesions suggest that reorganization affects activity across cortical hemispheres and provide a foundation for investigations needed to examine interhemispheric interactions that occur after injury.

Title: The shorthanded brain; functional connectivity across anterior putamen in top-notch expertise of stenography.

Authors: T. ITO[1], *T. MATSUDA[1], S. SHIMOJO[2]
[1]Brain Sci. Inst., Tamagawa Univ., Tokyo, Japan; [2]Biol./Comp. Neur. Systems, Caltech, Pasadena, CA

Abstract: Stenography, or shorthand, is a very unique set of skills, which necessitates orchestration of various functional modules in the brain, including auditory, linguistic, cognitive, mnemonic and motor, owing to intensive, nearly-life time training. Now that it is quickly replaced with voice recognition technology, we took the last opportunity to scan the top expert's brains in Japanese language, to obtain insights into how the brain can plastically reorganize itself under extreme pressures on accuracy/speed with nearly life-time overtraining. The fMRI data revealed that neural circuits for complex motor control were plastically reorganized especially around the left putamen, and that there was a morphological change. Though the putamen is known as the execution center of the acquired sensory-motor skills in its posterior region, the anterior putamen of stenographers had a high covariation with the cerebellum and the midbrian;

the stenographers had obviously different neural circuits from the well-known automated brain circuits. Indeed, the posterior putamen of the controls exhibited a high covariation with the cerebellum and the midbrain. The data indicate a vigorous plasticity in this area and its connectivity to those other relevant areas. The current study provides a rare dataset indicating such vigorous plastic reorganization of the brain, with massive overtraining but only in the adulthood.

Title: Selective acute reductions in motor cortex function by targeted ischemia in Channelrhodopsin-2 transgenic mice

Authors: *E. ANENBERG[1], P. ARSTIKAITIS[3], Y. NIITSU[4], J. D. BOYD[2], J. LEDUE[2], T. H. MURPHY[2]
[1]Neurosci., [2]Univ. of British Columbia, Vancouver, BC, Canada; [3]Stanford, Stanford, CA; [4]Cardiovascular-Metabolics Res. Labs., Daiichi Sankyo Co. Ltd, Tokyo, Japan

Abstract: Previously we have evaluated the effects of targeted occlusion of individual pial arterioles on somatosensory cortex function. We now evaluate the effect of targeted ischemia on motor function in Thy-1 line 18 channelrhodopsin-2 transgenic mice. Occlusion of individual arterioles within the motor cortex led to a micro-infarct that was verified using laser speckle contrast imaging. We assessed motor function using light based mapping procedure in channelrhodopsin-2 mice. This method allowed us to acquire a functional representation of forelimb muscles, thus allowing us to detect any ischemia-induced changes in its cortical representation within the first hours after stroke. Our results demonstrate that motor cortex appears to be very acutely sensitive to the effects of ischemia. Contrasting the differences in the immediate post-stroke changes between averaged electroencephalographic (EEG) (18±11% decrease) and electromyographic (EMG) (68 ±7% decrease) responses collected from each stimulation site within 40 minutes of stroke revealed a mismatch indicative of a substantial

amount of viable neurons that were incapable of transmitting to the muscle. Ischemia within a relatively small region of motor cortex severely impaired amplitude of EMG responses from stimulation in the ischemic region to 13 ± 4% of baseline. Notably, in areas that were non-ischemic, and selected for assessment based on the criterion of being the cortical location of greatest baseline motor output, there was a comparable decrease in EMG amplitude to 32.5 ± 5 % of baseline (n=6). Currently we are relating our electrophysiological findings to measures of blood flow. This relatively homogeneous deficit in motor output is present in regions adjacent to the infarct and is likely mediated by deficits in synaptic transmission. These results imply that motor cortex function is dependent a widely distributed synaptic network.

Title: Light-based mapping of reorganization after targeted stroke in sensorimotor cortex of Channelrhodopsin-2 mice

Authors: *T. C. HARRISON[1], G. SILASI[2], T. MURPHY[2]
[1]Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada; [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Recovery from stroke is hypothesized to involve the reorganization of surviving cortical areas. For example, the mouse forelimb motor cortex (mFL) often begins responding to sensory stimulation if the neighbouring forelimb sensory area (sfL) is damaged by stroke. When a cortical area is forced to take on a new function after stroke, is it impaired in the performance of its original role? To study the organization of sensorimotor cortex before and after stroke, we developed techniques for chronic light-based motor mapping of Channelrhodopsin-2 (ChR2) transgenic mice. This light-based method allowed us to perform longitudinal studies of motor

cortex that would not be feasible with conventional electrical motor mapping.
In our experiments, brief pulses of light stimulation were targeted to an array of cortical points and the motor activity evoked by stimulation was recorded at each of these points using non-invasive motion sensors. In animals with chronically implanted cranial windows, the brain could be mapped repeatedly for months. Used in combination with intrinsic optical signal imaging of somatosensory cortex, light-based mapping permitted ongoing evaluation of the functional organization of sensorimotor cortex before and after the creation of photothrombotic infarcts targeted to either forelimb motor or sensory areas.
During the pre-stroke baseline period, sFL and mFL were stable (mean weekly drift in motor map center = 0.55 ± 0.37 mm, n = 23 mice). Strokes in sFL, but not mFL or sham strokes, caused the sFL map to shift anteromedially toward mFL (n = 6,7, and 6 respectively, $p<.001$, 2-way ANOVA). The mFL representation was displaced from its baseline position by infarcts targeted to either sFL or mFL, but not sham strokes (n = 7,7, and 8 respectively, $p<0.01$, 2-way ANOVA). Despite the large-scale reorganization observed in sensorimotor cortex, we found that displacement of mFL (defined as displacement of the forelimb motor map from its pre-stroke position) was uncorrelated with displacement of sFL and vice-versa.
The rapid recovery of sensory and motor maps is an encouraging demonstration of the impressive capacity for spontaneous reorganization of cortical circuits. Although the sensory and motor cortices are heavily integrated in rodents, destruction of one of these regions had only limited consequences for neighbouring cortical areas. These results suggest that sensorimotor cortical neurons are adept at vicariously performing the function of stroke-damaged circuits. Future experiments will attempt to identify means of enhancing cortical reorganization after stroke.

Title: A sound-to-touch sensory substitution device for the severely hearing impaired

Authors: *S. NOVICH[1,2], D. M. EAGLEMAN[1,2]
[1]Neurosci., Baylor Col. of Med., Houston, TX; [2]Dept. of Electrical & Computer Engin., Rice Univ., Houston, TX

Abstract: There are at least 2 million functionally deaf individuals in the United States alone and an estimated 53 million worldwide. The cochlear implant (CI) is an effective solution for regaining hearing capabilities for certain populations within this group, but not for all. First, CIs are expensive, ranging from $40,000 to $90,000 depending on the age of the recipient. This places CIs out of economic reach for many. Second, CIs require invasive surgery. Third, there is low efficacy of CI implantation in early-onset deaf adults over the age of 12. Given this, there exists an important population of deaf individuals who would benefit from a hearing replacement that has low cost, does not involve an invasive procedure, and may have a higher efficacy for early-deaf adults over the age of 12.
To address these problems, we are developing a low-cost, non-invasive, plasticity-based solution to deliver auditory information to the brain. Specifically, we are developing a "vibratory vest" by which auditory information is captured, digitally processed, and delivered to the skin of the torso using small vibratory motors. We call our device the Vibrotactile Acoustic Coder, or the "VAC." The term for such a technique is sensory substitution, and has previously proven successful in allowing those who are blind to have visual experience through the tongue or skin. Although auditory sensory substitution systems (known as "tactile hearing aids") have been prototyped as early as the 1970s (and proposed as early as the 1920s), a successful project is only now made possible by recent strides in digital signal processing techniques, speech codecs, machine learning, and processor power and cost. Our device leverages all of these advances to develop tactile encoding algorithms that extend beyond the simple filtering and mapping of an incoming audio stream as found in previous tactile aids. Our device will cost an order of magnitude less than a CI, be non-invasive, and –we hypothesize– not require critical period plasticity for use. From a broader perspective, this endeavor will enable us to better understand and model how the brain processes any sort of sensory information, understand the properties and capabilities of the brain's plasticity, and help us develop a generic framework for designing effective sensory-substitution devices. In this poster, we will present the current development status of the VAC and preliminary results of a haptic time perception experiment.

Title: *In vivo* activation using channelrhodopsin-2 and voltage sensitive dye imaging in a stroke model reveals altered cortical relationships

Authors: *D. H. LIM, J. LEDUE, M. H. MOHAJERANI, T. H. MURPHY
Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Recently, we have developed a method of combining optogenetic cortical point stimulation with voltage sensitive dye (VSD) imaging in order to map functional relationships between cortical areas within the mouse brain (Lim et al., 2012). Here, we extend this method to a stroke model in order to map altered functional relationships after injury. B6.Cg-Tg (Thy1-COP4/EYFP)18Gfng/J transgenic mice, expressing channelrhodopsin-2 (ChR2) in subsets of deep layer pyramidal neurons, were given a targeted photothrombotic stroke to the primary sensory cortex and allowed to recover in their home cages. Eight weeks later, mice were given a large bilateral craniotomy and VSD (RH-1692) was applied to the cortex for imaging. Sensory stimulation of forelimb, hindlimb, whisker, and vision was used to map the primary sensory areas. These areas were then targeted for photostimulation, along with motor and associational areas that cannot be directly stimulated through peripheral activation. We found that the VSD response following sensory stimulation was delayed and prolonged in the injured hemisphere following stroke, as reported previously using VSD imaging in mice with a forelimb-targeted photothrombotic stroke (Brown et al., 2009). While sensory stimulation can be used to investigate connectivity in sensory circuits, it cannot be used to directly investigate associational or motor areas which may also be affected by stroke. Here, because ChR2 stimulation can be targeted to any cortical area in the transgenic mouse, we will evaluate the large-scale dysfunction caused by stroke in regions near and distant from the lesion. We chose twenty cortical sites to investigate using ChR2 point stimulation coupled with large-scale VSD imaging. Changes in intra- and interhemispheric connections between the cortical sites, including homotopic connections, were examined to determine which areas were most affected after stroke. Sham controls showed relatively equal intra- and interhemispheric connection strength in sensory, motor, and associational areas, while stroke animals showed decreased intracortical connection strength in the sensory and motor areas in the injured hemisphere, but increased intercortical connection strength in the motor areas of the injured hemisphere. The evaluation of the large-scale effects of stroke will be important for our understanding of the functional consequences of stroke, and may lead to better treatment strategies.

Title: Size discrimination in the absence of tactile feedback

Authors: *D. L. FREAR[1,2], C. K. OVERSTREET[2], E. H. MOUGHARBEL[2], S. I. HELMS TILLERY[2]
[1]Phoenix, AZ; [2]Sch. of Biol. and Hlth. Systems Engin., Arizona State Univ., Tempe, AZ

Abstract: Qualities like size, shape, texture, and compliance allow human hands to discriminate between objects in the environment. Tactile, proprioceptive, and visual feedback contribute to these judgments and allow skilled interaction with objects. We designed a series of experiments to identify the contribution of tactile sensation to performance in discrimination of small size differences. Subjects were instructed to grasp a set of seven boxes (ranging in width from 44 to 56 mm) within a virtual reality environment. The positions of their index finger and thumb were tracked by a motion capture system. After the subjects were acclimated to the virtual environment, visual feedback of the locations of the box and their fingers was removed. Instead, binary visual or auditory signals corresponding to the thumb or index finger were presented when the subject's fingers contacted the virtual object. The subject was then asked to identify if the current box was smaller, larger, or the same size as the previous object. Similar size discrimination experiments using physical objects, where tactile information was available, were also performed. Subjects correctly identified the size difference between objects more often during visual feedback than auditory feedback trials; discrimination was most accurate in the physical object condition where tactile feedback was available. Subjects correctly identified large size differences most often. In the visual feedback task, subjects responded correctly in approximately two-thirds of the trials with objects of a size difference -6mm and below and 10mm and above. In the auditory task, subjects correctly discriminated at this level only for the largest size difference (12mm). Although accuracy was low for some experimental conditions, subjects always discriminated at above chance levels. Subjects were more likely to indicate that objects were the same size during experimental conditions that lacked tactile feedback. In

follow-up experiments, we are examining size discrimination performance when artificial tactile feedback cues are presented.

Title: Discrepancy between neuronal activity and its associated hemodynamic response

Authors: *N. LI[1], P. VAN ZIJL[1], N. THAKOR[2], G. PELLED[1]
[1]F. M. Kirby Res. Ctr. for Functional Brain Imaging, Radiology, Kennedy Krieger Institute, Johns Hopkins University, Sch. of Med., Baltimore, MD; [2]Biomed. Engin., Johns Hopkins University, Sch. of Med., Baltimore, MD

Abstract: Improvements in MRI hardware are now being translated into detailed investigations of neuronal mechanisms associated with plasticity of cortical networks in human and animal models. Similar to other hemodynamics-based functional imaging techniques, the blood oxygenation level dependent (BOLD) fMRI signal is an indirect measurement of neuronal activity. Determining the degree of plasticity that occurs within and along cortical representations boundaries relies on the assumptions that the hemodynamic responses are co-localized and tightly correlate to neuronal activity. However, the exact relationship between the neuronal responses and hemodynamic responses remain unclear and under debates. The focus of our work was to investigate whether BOLD fMRI signal can be used to deduce about the underlying neuronal activity, and to what degree it co-localizes with neuronal activity. Combining optogenetic tools with electrophysiology, optical imaging of cerebral blood flow (CBF), and high-resolution BOLD fMRI, we sought to determine the correlation between the hemodynamic responses and neuronal activity. By localized excitatory neuronal activation of channelrhodopsin-2 (ChR2) stimulation in the rat primary somatosensory cortex (S1) we induced neuronal responses that were limited to the light stimulation S1 region (<500 μm). The neuronal activities in response to ChR2 stimulation differed in their oscillation frequencies, their cortical laminar profiles and spatial activation patterns across S1 representation compared to conventional forepaw stimulation. However, the cortical laminar profiles and the spatial extents

of the hemodynamic responses measured by CBF and BOLD fMRI induced by ChR2 and forepaw stimulation were indistinguishable. Both stimulations resulted in hemodynamic responses that were greater than 3 mm and only partially co-localized with the electrophysiology measured neuronal responses.
Thus, our results confirm the fundamental discrepancy between neuronal and hemodynamic responses, and suggest that resolving changes in cortical representation boundaries associated with plasticity may benefit from combining hemodynamic based measurements with neuronal stimulation via electrodes and optogenetics.

Title: Sniffing - whisking coordination in freely exploring mice

Authors: E. FONIO, G. GORDON, I. SARAF-SINIK, *E. AHISSAR
Dept Neurobiol, Weizmann Inst. Sci., Rehovot, Israel

Abstract: Smell and touch convey most of the information that nocturnal rodents collect in their natural environments. Being active senses, a critical factor determining the integration of their sensations relates to the degree of their coordination. While it has been known for nearly fifty years that sniffing and whisking can be coordinated, the dynamics of such coordination and its dependency on behavioral and environmental conditions are not known. Here we used high resolution video recordings and novel image-processing methods, allowing for the first time non-invasive and fully automatic acquisition of two sensing modalities (smell and touch) simultaneously. Alleviating the animals from external constraints enabled us to inspect freely ranging groups of mice in a natural like environment.
We analyzed the use of whisking and sniffing independently, their co-interactions and their relation to head movements in mice during free exploration. Data were recorded during emergence epochs of mice from their home cage to an exposed area. Active sensing parameters of each modality showed significant dependency on head velocity and on the direction of

locomotion (outbound or inbound movements with respect to the home cage). Correlations between sniffing and whisking were lower than those between left and right whiskers ($p < 0.001$), and were significantly larger during outbound exploration compared with inbound ($p < 0.01$). Both bilateral whisking correlations and sniffing – whisking correlations increased with whisking and sniffing power ($r > 0.9$, $p < 0.001$).
Overall, these data indicate that sniffing-whisking coordination is a dynamic process, possibly mediated by sets of coupled oscillators and likely to be controlled by high-level inter-modal motor-sensory loops.

Title: Somatotopic and motor mapping of speech articulators in human cortex

Authors: *D. CAREY[1], S. KRISHNAN[2], F. DICK[3], M. I. SERENO[3]
[1]Psychological Sciences, Birkbeck Col., Ctr. For Brain and Cognitive Develop., London, United Kingdom; [2]Psychological Sciences, Birkbeck Col., Ctr. for Brain and Cognitive Development, Birkbeck Col., London, United Kingdom; [3]Psychological Sciences, Birkbeck Col., Birkbeck/UCL Ctr. for Neuroimaging, Birkbeck Col., London, United Kingdom

Abstract: The articulation of speech sounds requires precise control of and coordination between different parts of the upper vocal tract, such as the lips, tongue, soft palate, jaw, and pharynx. Talkers are also exquisitely adaptable to perturbations of the position or movement of the articulators (such as the presence of food or other obstructions), suggesting a high degree of integration across somatosensory and motor representations. Due in part to the difficulty in stimulating inside the mouth, and in isolating movement to discrete articulators, there are few detailed fMRI maps of cortical representations of the vocal apparatus. Moreover, it is unclear how such maps mesh with those of more abstract speech representations such as place of articulation. Here, we used phase-encoded fMRI to map motor and somatosensory representations of the relative position of articulators by having phonetically-trained participants produce trains of individual voiceless stops (/pə/, /tə/, /ʈə/, /cə/, /kə/, /ʔə/) that varied systematically from front to back place of articulation and then sulcus-based spherical surface-

averaging to combine complex-valued mapping data across subjects. Across participants, there was a consistent graded map of place of articulation generally spanning the central sulcus and primary motor and somatosensory areas, and moving from superior to inferior as place of articulation changed from front to back. Production of bilabials preferentially activated somatosensory regions slightly more than halfway along the medial to lateral length of the central sulcus, with activation related to alveolar, palatal, and retroflex stops moving more inferiorly, and tending to occur in curved bands across primary somatosensory areas, primary motor areas, and secondary somatosensory areas. Stops produced at back places of articulation (velar and glottal) activated the inferior aspect of the central sulcus near the subcentral gyrus but less robustly and more variably across participants. Control block design experiments supported the mapping of front to back place of articulation to parallel sequences of medial to lateral positions in S-I and M-I. To our chagrin, there was little evidence for articulation-specific mapping in inferior or middle frontal gyri.

Title: Whisker movements may reveal spatial attention: A computational model of active sensing control in the rat

Authors: *T. J. PRESCOTT[1], B. MITCHINSON[2]
[1]Psychology, Univ. Sheffield, Sheffield, United Kingdom; [2]Psychology, Univ. of Sheffield, Sheffield, United Kingdom

Abstract: Much effort continues to be focused on understanding signal processing in the rodent whisker sensory system. In contrast, the control of whisker movement has been the subject of relatively limited investigation. However, an understanding of whisker movement is critical to understanding the sensory signals present in the behaving rat, further, whisker control may also provide a new window into the internal state of the animal.
Several distinct observations of relationships between whisker movement and other variables

have now been reported that indicate the influence of the environment, or the animal's intentions, on whisking behavior. These include (i) that whisker protraction angles are adjusted bilaterally toward the direction of a future head movement (head-turning asymmetry); (ii) that protraction angles are adjusted to be reduced/increased on the side of the animal near to/away from a nearby object (contact-induced asymmetry); (iii) that the angular spread between the whiskers is reduced during surface contacts (spread reduction); (iv) that there is an increase in protraction angle towards the location of an anticipated contact; and (v) that animals engaged in rapid goal-directed locomotion often employ strong protraction. We are motivated to identify a model that can account for all of the above through a single mechanism. One clue, is the observation that unilateral contact often elicits head-turning towards the contact point suggesting that contact triggers attention, which, in turn, typically elicits orienting. We hypothesize, accordingly, that an important hidden variable driving the modulation of whisker movement is the locus of spatial attention--that is, the region of the local environment to which the animal's attention is currently directed, directs both orienting head movements and appropriate regulation of the movement of the vibrissae.

Here we report on a concrete model that confirms this expectation, showing that the model also expresses head-turning asymmetry, contact-induced asymmetry and spread reduction. We further argue that both reaching towards anticipated contact and strong protraction during locomotion, would also be expressed by the model were appropriate inputs available. We conclude that this attentional model can account, in principle, for all major observations to date of the modulation of periodic whisker movement, suggesting that whisker movements could also be used as an experimental tool to reveal the locus of attention of a whiskered animal. The current model is abstract in form, however, we propose that the superior colliculus (SC) is a candidate neural substrate for the implementation of such a mechanism.

Title: The relationship between locomotion and whisker touch sensing behaviours in the adult rat is mediated by familiarity with the environment

Authors: *K. P. ARKLEY, R. A. GRANT, B. MITCHINSON, T. J. PRESCOTT
Univ. of Sheffield, Sheffield, United Kingdom

Abstract: As rats are nocturnal, they cannot depend on vision to navigate through dark burrows. Instead, they rely heavily on their sense of touch to explore and interpret their environment, predominantly using their whiskers. Research has implicated that whiskers are used to perform behaviours requiring precise and coordinated movement such as climbing (King et al., J Zool, 285, 172-179, 2001), swimming (Ahl, Vet Res Commun, 10, 245-268, 1986), food acquisition and prey capture (Favaro et al., Neuroscience, 176, 318-327, 2011), but a detailed description of the behaviour (performed by whiskers, head and body) has been ignored. Furthermore, whisking and locomotion behaviour is well correlated over the course of development (Grant et al., Dev Psychobiol, 54, 151-168, 2012), leading us to hypothesise that whisking and locomotion are closely coupled in the adult rat.

We used high-speed videography to record the whisking and locomotion behaviour of food-deprived rats trained to run a circuit for food reward. The experimental arena was manipulated to either disrupt whisking during locomotion (by inclusion of obstacles), or disrupt continual locomotion (by means of a holey floor); a smooth floor with no obstacles was used as a control condition. We filmed the animals moving along the central trackway of our arena using a Photron high-speed camera (500fps) and used a front-silvered mirror to obtain both side-on and overhead views. Beneath the glass floor, illumination from a custom-built light box ensured a clear silhouette of the whiskers in both views, and a second camera provided a good view of foot placements from our pedobarograph. Recording of several seconds duration were made on each training day, automated whisker tracking and Fourier analysis were then used to extract locomotion speed, head lift, and whisking amplitude and set-point. The cross correlation between whisker and front feet positioning was examined, as well as the relationship between locomotion and whisking variables as mediated by familiarity with the environment.

Our findings indicate that increasing familiarity with the environment is correlated with increasing locomotion speed and head lift, and non-exploratory (static) whisker positions that serve as a ‘look-ahead’ object-detector (i.e. lower amplitude, more protracted). However, when rats previously trained in the control environment are introduced to unexpected obstacles, high running speeds are also accompanied with more exploratory whisking (higher amplitude, less protracted). This suggests that locomotion and whisker movements can be controlled independently of one another to produce a more flexible behavioural repertoire.

Title: Induction of vasodilation predicts increased sensory-evoked firing

Authors: *D. L. VIERLING-CLAASSEN, C. I. MOORE
Neurosci., Brown Univ., Providence, RI

Abstract: We analyzed the impact of induced vasodilation on sensory evoked responses in single units recorded in anesthetized (ketamine/xylazine) mouse barrel cortex. Electrophysiological data were obtained using Neuronexus tetrodes and hemodynamics tracked using Laser Doppler (Perimed) measurements of blood flow. Analyses were conducted on 9 experiments (13 units) in which dilation was successfully induced by Pinacidil application, a pharmacological approach previously shown to selectively target vascular smooth muscle in the neocortex. These data were compared to 7 experiments (18 units) in which identical procedures were followed but drug was not administered.

Following induction of vasodilation and increased blood flow rate, a majority of neurons showed increased sensory evoked firing. This finding generally replicates prior observations from rat barrel cortex obtained under thiopental anesthesia (Cardin et al., 2008 *SfN* Abstracts). This increase in evoked firing showed two apparently distinct epochs, one proximal to the initial dilation event, and one several minutes later. For the initial epoch, the relative amount of increased evoked firing rate was positively correlated with change in blood flow. Firing increases were typically not observed in units in the background firing measured in the inter-stimulus interval between sensory stimuli (5 second ISI). In aggregate, these findings imply increased signal to noise ratio for the relay of sensory information induced by vasodilation and/or blood flow changes.

We also observed a strong correlation between blood flow and the change in mean firing rate in the absence of stimulation 15 minutes post-dilation induction. Analysis of control runs showed no systematic increase over time in sensory evoked firing rate but did show positive correlations between spontaneous changes in blood flow and sensory evoked rate.

Title: Gentle cutaneous stimulation inhibits noxious heat-induced autonomic responses in conscious humans independently of perception and texture discrimination

Authors: *H. HOTTA[1], N. WATANABE[1], S. MIYAZAKI[2], Y. MUKAINO[3]
[1]Dept. of Autonomic Neurosci., Tokyo Metropolitan Inst. of Gerontology, Tokyo, Japan; [2]Dept. of Acupuncture and Moxibustion, Teikyo Heisei Univ., Tokyo, Japan; [3]Fac. of Sports and Hlth. Sci., Fukuoka Univ., Fukuoka, Japan

Abstract: Background and purpose.
Pain can be reduced by touching the skin near the painful site. However, the mechanism has not yet been fully clarified. Recently, we found that gentle mechanical cutaneous stimulation can inhibit the somato-cardiac sympathetic C-reflex elicited by stimulating unmyelinated C afferent fibers of the plantar nerve in anesthetized rats. The effect was dependent on the texture of touching object. Using the two different textures, the present study examined whether touch affects autonomic responses and subjective pain intensity induced by noxious stimulation in humans, independently of perception and texture discrimination.
Methods.
The present study was designed as a cross-over, double-blind, randomized trial using two different types of skin stimulation tools of 11-mm diameter - an elastomer brush (with 417 microcones) and a flat elastomer disc. Twenty healthy adult males (24.4 ± 6.3 years old) participated in the study. The experiment consisted of two 40-minute sessions. While heart rate (HR) and amplitude of digital pulse wave were measured, heat stimulation (46 degree Celsius for 45 sec) was delivered by a Peltier thermode. Subjective pain intensity was measured with a 0-10 visual analogue scale (VAS). A cutaneous stimulation tool was applied, over the right medial malleolus with an adhesive plaster, for a period of 10 minutes. We asked the participants whether they perceived differences in the two stimulation tools, and confirmed that the difference in the texture had not been discriminated.
Results.
Heat stimulation induced pain (4.3 to 9.7 on the 0-10 VAS scale), and changed HR (by 1 to 22 bpm) and pulse wave amplitude (by 0.0023 to 0.33 V). Although VAS score was not significantly affected, magnitudes of autonomic responses were reduced by the touch with the microcone. The heat-induced HR response was significantly inhibited (by 22%) during the touch compared to the pre-touch level. Heat-induced changes in pulse wave amplitude were also significantly inhibited during the touch (by 27%), continuing after the touch was ended (by 28%). On the contrary, touch with the flat disc did not produce constant changes in neither heat-induced autonomic responses nor VAS scores.

Conclusion.
The present study demonstrated that skin touch can inhibit autonomic responses to noxious heat, depending on the texture of the object, but independently of texture discrimination. This result is consistent with our previous study on anesthetized animals. Therefore, we conclude that an inhibition of nociceptive transmission into autonomic responses by gentle mechanical cutaneous stimulation could occur independently of sensation and cognition.

Title: Peripheral ultrasonic neurostimulation combined with fMRI and EEG for the mapping of somatotopic brain circuitry.

Authors: W. LEGON, A. ROWLANDS, A. OPITZ, T. SATO, *W. TYLER
Virginia Tech. Carilion Res. Inst., Roanoke, VA

Abstract: A variety of peripheral neurostimulation procedures are used in the study and clinical evaluation of somatosensory nervous system function. The energy modalities employed by these methods span mechanical, thermal, electromagnetic, and photonic domains. Broadly implemented tools for evoking somatosensations include lasers, contact peltier probes, Von Frey hairs and other mechanical probes, electromagnetic coils, and piezoelectric elements. Less implemented, ultrasound (US) applied to the periphery has been described to be capable of evoking diverse somatosensations. However, these reports have been primarily subjective and have been lacking neurophysiological validation. To substantiate the use of US for somatosensory activation, we recorded evoked-potentials and BOLD response to both right and left US finger stimulation. Results indicate US to be capable of eliciting reliable evoked potentials including a large double-peaked vertex potential (N1/N2) peaking at 110 ms and 160 ms respectively. The same stimulation resulted in BOLD activation in areas involved in somatosensory discrimination including the primary somatosensory cortex (S1), parietal operculum (Op) as well as brain
regions involved in hierarchical somatosensory processing such as supramarginal gyrus (SMg) and areas commonly activated in response to salient and noxious stimulation including anterior

middle cingulate cortex (aMCC) and insula. We also demonstrate the ability to elicit an increase in subjective report of noxious and thermal sensation concomitant with
a change in evoked potentials and BOLD activations as a result of changing ultrasound stimulus parameters. Based upon these observations, we conclude focused pulsed ultrasound can be useful for interrogating and mapping somatosensory brain circuits, which may permit new paths for the study, diagnosis, and treatment of peripheral nerve injury, dysfunction, and disease.

Title: Statistics of tactile exploration during multimodal sensory navigation

Authors: *T. CELIKEL[1], D. H. HERMAN[2]
[1]USC, LOS ANGELES, CA; [2]USC, Los Angeles, CA

Abstract: Navigation requires sensory information, and most sensory information during navigation arrives across modalities. To address the relative contribution of visual and tactile information in temporal statistics of navigation, we trained adult mice to locate a target platform on the gap-crossing task while illumination of the environment was randomly varied between white-light (i.e. light) and infrared-light (i.e. dark=no visible light) conditions across sessions. Animal mobility on the task and the time animals spent locating the target while positioned at the gap were quantified using motion sensors. The results showed that illumination condition does not contribute to overall likelihood of successful object localization, maximum gap-distance at which mice can locate the target of interest, duration of sensory exploration at the gap or the trial duration which suggest that information that arrive from visual and tactile modalities are highly redundant in determining the location of the target, and likelihood for mice to locate the object. The only independent variable that significantly varied across light and dark conditions was the amount of time that mice spent exploring the gap when they failed to cross onto the target

platform which is probably due to preferential exploration of visual information other than the target platform at the gap. These results argue that tactile modality is the predominant modality mice use to locate objects on the gap-crossing task independent from whether or not there is simultaneous visual information.

Title: Spinal cord and brainstem response to stepwise and block design thermal stimulation paradigms: An fMRI study

Authors: *R. BOSMA[1], C. DOBEK[2], M. BEYNON[2], P. STROMAN[2]
[1]Queen's Univ., Kingston, Canada; [2]Queen's Univ., Kingston, ON, Canada

Abstract: Spinal cord functional magnetic resonance imaging (fMRI) can be used to produce maps of neural function and therefore enables non-invasive visualization of spinal cord responses to peripheral thermal sensory stimuli. Given the limited temporal resolution of this technique, long stimulation paradigms are required to obtain enough data to accurately characterize the spinal cord response. However, repeated stimulation of unmyelinated C-polymodal fibers and thermoreceptors results in response depression, and these receptors quickly acclimate to an adaptation temperature. Therefore, careful selection of the stimulus paradigm is required to maximize the spinal cord response. The purpose of this study is to evaluate the characteristics of the spinal cord and brainstem response to peripheral stimulation in which temperature is raised in a stepwise fashion, in order to enhance receptor responses, compared to the conventional block design.
Functional MRI studies of the spinal cord and brainstem were carried out in healthy volunteers in a 3T Siemens Magnetom Trio. An MR-compatible Peltier thermode (Medoc) was placed on the right hand of participants and provided thermal stimuli during the experiments. Two sensory

stimulation paradigms were employed; a stepwise design and a block design. In the stepwise condition the temperature was raised from 32 ^{0}C (baseline) to 37 ^{0}C, held for 13 seconds and raised to 42 ^{0}C, held for 14 seconds and raised a final time to 45 ^{0}C for 20 seconds. In the block design condition the temperature was raised from baseline to 45 ^{0}C and sustained at that temperature for 47 seconds. The ramp rate was 2 ^{0}C/second for all conditions.
Spinal cord data were analyzed using custom software (written in MatLab). A time series analysis was carried out by means of a general linear model (based on SPM) to identify areas responding to the thermal stimulation. Connectivity analyses were then conducted to identify the sensory network and determine interregional spinal cord and brainstem activity correlations during thermal stimulation.
Robust ipsilateral dorsal horn activity was evident in the stepwise condition, while weaker contralateral dorsal and ventral activity was more prominent in the block design. Stepwise results also revealed consistent activity in regions of the rostral medulla known to be involved in sensory processing and in a region in close proximity to the periaqueductal grey region in the midbrain.
Results from this study lay the foundation for ongoing studies to assess the changes that occur at each of these relay points as a result of trauma and may elucidate neurological changes which affect functional outcomes.

Title: Motor-Sensory strategies of object localization in rats

Authors: *E. ASSA, I. SARAF - SINIK, E. AHISSAR
Weizmann Inst., Rehovot, Israel

Abstract: Perception is the process of gaining information about the outside world. The dynamical nature of perception dictates a mode of operation in which motion of the sensory organ and sensation are mutually dependent. Motor-sensory interactions should probably be

optimized to the perceived features. A motor-sensory strategy is defined here as the motor plan selected by the animal during a specific perceptual task.
Here, we seek to identify the motor-sensory strategy underlying object detection and localization in rats in terms of “invariant” and “modulated” parameters. Both types are subjected to brain control, which maintains invariant parameters constant between task repetitions and under different environmental conditions by changing modulated variables. Next, we demonstrate how motor-sensory strategies exhibited by freely behaving rats facilitate acquisition of information during perception.
Rats were trained to report the presence (‘detection’) and locations (‘localization’) of two vertical poles, bilaterally positioned in their path. The report was based on a three-alternatives-forced-choice scheme, in which the location of the rewarding drinking tube (‘sipper’) was associated with the presence and relative location of the two poles. The task was repeated with and without wind perturbation. Head and whiskers were tracked with high-speed video and analyzed off-line.
Motion parameters of the head and whiskers were significantly modulated along a trial, in a stereotypic manner, such that task progress could be divided into five sequential behavioral phases: (*i*) detection (*ii*) early and (*iii*) late localization (*iv*) sipper approach and (*v*) sipper localization. Analysis of the localization phases (ii and iii) indicate that relative object location is first encoded by bilateral temporal difference of contacts and later by whisker angular difference. The motor-sensory strategy displayed by the rats supported this coding scheme by keeping whisking velocity and head angle relatively invariant during localization also under wind perturbations while modulating whisker set-points and radial distance of whisker-object contact. These observations emphasize the active nature of perception and suggest that motor-sensory strategies are inherent components of perception.

Title: Ownership and disownership of hands in a patient recovering from somatoparaphrenia

Authors: *C. DIJKERMAN[1,2], H. E. VAN STRALEN[1,2], L. J. KAPPELLE[2], M. J. E. VAN ZANDVOORT[1,2]
[1]Helmholtz Inst., Utrecht Univ., Utrecht, Netherlands; [2]Dept. of Neurol. and Neurosurg., UMC Utrecht, Utrecht, Netherlands

Abstract: It may appear self-evident that we have ownership over our own body. Nevertheless, ownership of (part of) our body can be disrupted after cerebral damage, as for example is the case in somatoparaphrenia. In this disorder, patients attribute ownership of their contralesional limb to another person. So far, most studies of patients have been descriptive, depending on a verbal report of their experience. In the current study we aimed to experimentally manipulate body ownership in a patient recovering from somatoparaphrenia using the rubber hand illusion (RHI). In this illusion synchronous visuo-tactile stimulation results in the subjective experience of a rubber hand being part of the body, and reduced ownership over their own hand. This can be measured through questions about the disowned hand, a proprioceptive displacement of the perceived position of the hand towards the rubber hand or the feeling of a lower temperature in the disowned hand.
We assessed a 78-year-old female, who suffered a right-hemisphere stroke about two weeks prior to the testing. Shortly after the stroke, she did complain that she experienced her left hand no longer belonging to her body, but felt as if her arm belonged to her father in law. This feeling was subsided at the time of testing. Clinical assessment showed limited contralesional sensorimotor impairments and no cognitive deficits.
The RHI was induced for her left disowned hand as well as for her unimpaired right hand through synchronous stroking of her own hand and a rubber hand. Asynchronous stroking was used as control condition. All measures of the RHI, questions, proprioceptive displacement as well as skin temperature, indicated that she experienced an enhanced RHI with her left compared to her right hand. Moreover, there was no difference in the strength of the RHI between the synchronous and asynchronous stroking for the left hand. This suggests that ownership over the left hand was more easily disrupted than over the normal right hand and that visual presentation of a left rubber hand was sufficient to induce this disruption.

Title: Emergent hierarchical control via novelty management of multiple motor-sensory loops

Authors: *G. GORDON[1], E. FONIO[2], E. AHISSAR[2]
[2]Neurobio., [1]Weizmann Inst. of Sci., Rehovot, Israel

Abstract: When encountering novel environments animals perform complex yet structured exploratory behaviors composed of elementary and repeatable motor primitives. We present a hierarchical model that manifests a delicate balance between learned novelty-seeking and novelty-avoidance primitives.
Exploration motor primitives are learned via hierarchical curiosity loops, in which each loop is a manifestation of intrinsic-reward reinforcement learning. Each loop converges to a behavior that optimizes the learning process of a specific feature of the environment. The transition between primitives is governed by novelty management principles, which dictate that novelty should be pursued; yet when too much novelty is accumulated, the agent retreats to a ``base state".
We implement the model in two scenarios: the rodent whisking system and mice exploration of novel arenas. In the former, we model two loops, the first learning whisker self-motion and the second seeks to localize objects in the environment. We show that periodic whisking and object palpation emerge as the converged behaviors of these loops.
The structured increase in extent and complexity of mice exploration of novel arenas is also captured by the same model. The hierarchical curiosity loops account for the increased dimensionality of behavior, whereas the novelty management principle accounts for the gradual increase in scope and the recurrent retreats to the home base. Here we model locomotion behavior by three loops, which converge to circling in corners, wall attraction and open-space exploration, respectively.
This work shows that the same set of novelty management principles can explain the exploratory behavior in two different modalities: whisking and locomotion. We propose that these principles may be common to exploratory behavior in general.

Title: Sensorimotor computation for adaptive whisking during multimodal sensory navigation

Authors: *D. H. HERMAN[1], K. WALLIN[2], T. CELIKEL[2]
[1]Neurosci, USC, LOS ANGELES, CA; [2]Neurosci., USC, los angeles, CA

Abstract: Previously we have shown that mice perform close-loop sensorimotor computation to locate objects of interests in their immediate environment. When animals were allowed to explore their environment using their whiskers in darkness, whisking amplitude was influenced by the recent history of tactile information collected during navigation. In natural environments however, most sensory information arrives across multiple sensory modalities, driving animal to integrate multimodal sensory information. In this study, we built on our previous observations on the rules of sensorimotor computation during adaptive whisking and quantify the role of visual information on tactile exploration during object localization while mice collect visuotactile information about their environment by randomly varying the illumination between (white) light and dark across sessions on the gap-crossing task. Our results show that, independent of the illumination, mice continue the adaptive whisking strategy where the protraction setpoint is predictive of the relative distance to the target. In contrast, in the dark, the whisking protraction and retraction setpoints are positioned rostrally as compared to whisking in the light, and that the magnitude of this difference is monotonically related to both the nose distance to the target and the current gap-distance. Although there were no differences in whisking frequency, bilateral whisking symmetry, and head-whisker motion across the illumination conditions, there was significantly greater variability in whisking amplitude in dark which decreased as the animal approached to the target. These results argue that visual information during multimodal visuotactile exploration contributes to development of search strategies (i.e. where to whisk) although motor control of whisker position relies on the tactile information.

Title: Fingertip deformation during the onset of a tangential sliding movement.

Authors: *B. DELHAYE[1,2], P. LEFÈVRE[1,2], J.-L. THONNARD[1]
[1]Inst. of Neurosci. (IoNS), Univ. catholique de Louvain, Brussels, Belgium; [2]Inst. of Information and Communication Technologies, Electronics and Applied Mathematics(ICTEAM), Univ. catholique de Louvain, Louvain-la-Neuve, Belgium

Abstract: In daily life, we manipulate objects that have different physical properties (mass, surface, shape). Most of the time, we succeed in this task and prevent the objects dropping from the hand. This is explained by the fine coordination between the load force (LF), the tangential force due to the object weight and inertia, and the grip force (GF), the normal force applied to the objects to counteract the LF. This fine coordination is possible with the help of the cutaneous feedback from the fingertips mechanoreceptors. These respond to the stresses and strains created by the deformation of the skin during object grasping and manipulation. Measuring the fingertip skin deformation before and during slipping may thus contribute to better understand how we can prevent the objects from slipping during their manipulation.
In this study, we used an imaging system to record the fingertip deformation during the onset of tangential sliding movements of the fingertips on a glass surface. The constraints were applied passively to the fingertip of subjects in different directions: front-rear translations, left-right translations and clockwise-counterclockwise rotations. A robotic system controlled the normal force applied to the fingertip and the tangential speed. The contact forces and torques were recorded. Using computer vision techniques, the contact area was extracted from the images and the relative velocity field between the glass and the fingertip contact area was computed during the whole sliding phase. An ellipse was fitted to the contact area during the whole slip in order to measure the displacement (for translations) and the tilt angle (for rotations) of the contact area. Results showed that the skin deforms in a complex way from a full stuck state to a full slipping contact. During this transition, while the tangential force was monotonically increasing, the skin progressively slipped on the plate, beginning from the border of the contact area and ending at the central zone, and forming a velocity gradient from the border to the center. This behavior was observed for both translational and rotational movements. This transition from a full stuck state

to a full slip was accompanied by a reduction of the contact area, which then stayed constant during full slip. The skin displacement, due to the elasticity of the finger skin, was measured. This displacement was significantly larger in lateral movements in comparison with front-rear movements. The direction of rotation did not affect the absolute value of the tilt angle significantly. The form of the decreasing stuck region was also critically dependent on the loading direction and the moisture of the fingertip.

Title: Short-term adaptation in the human somatosensory cortical network due to repeated stimulation of the hand and face

Authors: *L. VENKATESAN[1], M. POPESCU[4], E. POPESCU[4], S. M. BARLOW[1,2,3]
[1]Neurosci., [2]Speech-Language-Hearing, [3]Human Biol., Univ. of Kansas, Lawrence, KS;
[4]Hoglund Brain Imaging Ctr., Univ. of Kansas Med. Ctr., Kansas City, KS

Abstract: OBJECTIVE: To use magnetoencephalography (MEG) to study the short-term adaptation response of the human somatosensory cortical network due to repeated stimulation of the hand and face using a custom-built pneumotactile stimulator called the TAC-CELL. METHODS: The TAC-CELL is a custom molded (O.D. = 15mm, I.D. = 6mm, H = 6mm) pneumatic actuator with a rise time (10-90%) of 8.5 ms. A custom non-commutated servo motor operating under position feedback and computer control was used to pneumatically charge the TAC-CELL. A whole-head 151-channel MEG scanner was used to record the cortical response to a pneumatic tactile stimulus that consisted of a repeating 6-pulse train (50-ms pulse width, intertrain interval = 5 s, 125 reps/train rate, train rates [2, & 4 Hz]). Nine healthy females (Mean age = 24.2 years [SD = 3.2]) with no history of neurological disorders participated in this study. A double-adhesive tape collar secured the TAC-CELL at two locations, including the 1) glabrous

surface of the right index finger, and 2) right non-glabrous surface of oral angle. Source reconstruction, dipole localization, estimation of dipole strength peak amplitudes, and latencies were performed using CURRY software.
RESULTS: Peak dipoles were localized to the left primary somatosensory cortex (SI) and posterior parietal cortex (PPC) for hand stimulation, and to the contralateral left SI for face stimulation. Dipole locations for both hand and face stimulation were consistent with the somatotopic organization in SI. The PPC component for hand stimulation was more medial (mean $\Delta x = 3$ mm, SD = 5 mm), more posterior (mean $\Delta y = -4$ mm, SD = 10 mm), and more superior (mean $\Delta z = 2$ mm, SD = 3 mm) when compared to SI. Peak dipole strength was significantly dependent on stimulation frequency ($p=.026$), cortical response component ($p<.0001$), and pulse-index number ($p<.0001$). Peak SI and PPC latency for hand stimulation was observed at 66± 6 and 96± 6 ms respectively. Peak SI latency for face stimulation was detected at 52 ± 6 ms.
CONCLUSIONS: TAC-CELL stimulation of either the face or hand with patterned pneumatic stimulus was highly effective in inducing short-term adaptation of somatosensory cortical network. The significant difference between the latencies of peak dipole strengths of hand and lip SI, and hand PPC is attributable to the difference in axon length and distance from the mechanosensory nerve terminals in the face and hand to their central targets in SI. A short delay in the PPC response reveals the hierarchy in the serial-processing mechanism that exists in the somatosensory cortical network. The lack of PPC response during face stimulation may be due to the absence of face representation in the PPC.

Title: Somatosensory prediction in haptic tracing

Authors: *M. FLANDERS[1], J. TRAMPER[2]
[1]Dept Neurosci, Univ. Minnesota, MINNEAPOLIS, MN; [2]Donders Inst. for Brain, Cognition and Behavior, Nijmegen, Netherlands

Abstract: When you run your index finger along an unfamiliar curved surface, with your eyes closed, haptic guidance mechanisms come into play. Tactile and propriocepive inputs from the hand and arm are used on-line to continuously control the movement, feedback corrections being combined with feedforward predictions. This study sought to determine what sort of feedforward predictions the somatosensory system is capable of. Human subjects interacted with a large-workspace 3D Phantom force-feedback robot. The distal phalanx of the right index finger was strapped into a small, light-weight sled and virtual surfaces were programmed at the fingertip. Tubular shapes were created in vertical planes: various elliptical hoops (40 cm long axis) with abruptly flattened regions, or tilted Limaçon shapes of a similar size, where the surface curvature varied continuously according to cosine functions (see Figure). At the beginning of each trial, the fingertip popped into the lumen of the tube (4 cm diameter) and then moved clockwise along the interior surface pressing outward (contact forces are color-coded for intensity in the Figure). In the ellipse experiment, subjects anticipated abruptly flattened regions very poorly, even after repeated laps around a given hoop, each of which was in the same frontal plane. In contrast, despite the more complex and 3D nature of the Limaçon experiment (with titled shapes in rotated vertical planes), finger speed smoothly varied in phase with the 2/3 power law prediction, and voluntary modulation of contact force also indicated prediction of upcoming curvature increases and decreases. The results suggest that, without vision, it is difficult to anticipate the spatial location of an abrupt somatosensory event (a corner), but in contrast, smooth changes in curvature can be anticipated using a feedforward predictive mechanism.

Title: A novel stimulation method based on a neuromorphic mechanoreceptor model for haptic illusion

Authors: K. GWAK, J.-C. PARK, *D.-S. KIM
Electrical Engin., KAIST, Daejeon, Korea, Republic of

Abstract: Tactile stimulation has gained increasing importance in several areas including human-computer interface to provide higher intuitiveness and enriched sensory stimulation for users. The principle aim of this study is to provide an illusory tactile sensation such as the shape or the texture of any objects to human. Haptic illusion generation system employing a developed vibrotactile stimulator, 6 by 4 pin-array type with 3mm nominal pitch, and a computational model of human distal finger pad is implemented to improve the veracity of tactile stimulation. The stimulator consists of 24 tiny ultrasonic linear motors operating periodically in the range of 0 to 100Hz within 200μm amplitude. Each motor is calibrated and computationally modeled using laser displacement sensor. Previously reported RA mechanoreceptor models are applied to simulate the human distal pad. The model employs integrate-and-fire neuron model with a specified refractory and hyperexcitability period. For a specified target haptic illusion such as an inclined bar, optimization algorithm with subgradient method derives the corresponding spatio-temporal stimulation patterns for 24 motors based on the stimulator and the distal pad model. Bar orientation discrimination experiments are conducted for human subjects using the developed illusion generation system. The results show that the stimulator can reliably present illusory bar with specified orientations. This preliminary result implicates the important possibility to generate haptic illusion. Not by scanning all possible combinations of stimulus through human

experiments, one can considerably shrink the range of combinations before the human experiments. Furthermore, hints for complicated haptic illusions, which are not able to be just anticipated by researcher, can be derived. Once various illusions are reliably generated, the method will be applied to numerous fields from haptic UI to prosthetic skin.

Title: A methodology for recording and online analysis of electrocorticographical data from freely behaving rats under spatiotemporally controlled tactile stimulation.

Authors: *A. FRANSEN, E. MARIS, G. DIMITRIADIS
Dep. Bio- en NeuroPsychologie, Radboud Univ., Nijmegen, Netherlands

Abstract: We have developed a methodology for the recording of electrocorticographical (ECoG) data from freely behaving rats while controllably stimulating the corresponding somatosensory regions on the rats' snouts. These recordings cover a large part of the rat's brain and involve areas that, up to today, have been accessible only through wire recording experiments with limited precision. This setup allows for both online and offline analysis. Our methodology comprises of a surgery process, an experimental setup with live stimulation and online experiment control, and data analyses that make use of an in-house developed 3D rat brain model.
Our surgery protocol allows us to chronically implant a 32 channel flexible polyimide-based ECoG grid onto the lateral side of the rat's cortex, while leaving the jaw muscles intact. The grid covers motor, somatosensory and auditory regions. This setup provides high quality, stable recordings for more than 5 months.
The experimental setup comprises two parts. One is the use of a head-mounted tactile stimulator on the rat's upper lip. This stimulator is easy to manufacture (utilizing 3D printing and limited post processing) and gives controlled stimulation of the upper lip in a freely behaving rat. The second part of the setup is a software package, which expands on software for human Brain Computer Interface (BCI) experiments (i.c., BCI2000). This makes possible BCI experiments in small animals that involve online feedback about the animal's brain state.

Finally, our grid recordings need to be accurately co-registered with the brain surface over a large cortical area. For this purpose, we constructed a 3D model of the rat's brain using the LONI rat atlas with co-registration of functional areas taken from the Paxinos atlas.

Validation

To show that our data collection and head-mounted stimulator systems operate in unison, we have recorded data both from anesthetized and awake rats. To establish the validity of our method, we first conducted receptive field mapping experiments under anesthesia. These experiments convincingly show that event-related potentials (ERPs) discriminate between the different stimulation areas on the rat's upper lip.

Moreover, we have also conducted stimulation experiments in freely moving rats. Importantly, with identical tactile stimulation, there are important differences between the ERP maps obtained under anesthesia and during wakefulness. With respect to behavior, the rats can be trained to perform simple detection and identification tasks whilst carrying the stimulator. The system therefore allows for a full spectrum of behavioral experiments with controlled sensory stimulation.

Title: Zinc transporter-3 knockout mice display decreased acuity in a novel whisker-dependent texture-discrimination task

Authors: *H.-P. WU[1,2], R. DYCK[2]
[1]Calgary, AB, Canada; [2]Psychology, Univ. of Calgary, Calgary, AB, Canada

Abstract: Zinc is intimately involved in the regulation of synaptic function in the mammalian brain. A subset of telencephalic neurons sequesters zinc in their synaptic vesicles where it is co-released with glutamate. At the synapse, zinc can interact with a variety of receptors and modulate neurotransmission. One prominent example is the modulation of NMDA receptor activity by zinc, which implicates zinc in the regulation of synaptic plasticity. We have demonstrated, in previous studies, robust experience-dependent alterations in the levels of

synaptic zinc within the somatosensory and visual cortices of mice. We established that sensory deprivation significantly increased the level of vesicular zinc in the respective sensory cortices, while stimulation decreased levels. In the present study, we investigated the role of zinc in somatosensation. Specifically, we measured texture discrimination by zinc transporter-3 knockout (ZnT3-ko) mice using their mystacial whiskers. ZnT3-ko mice do not have detectable levels of vesicular zinc within the brain. Vesicular zinc is found in high concentrations within limbic structures and is involved in learning and memory processes such that ZnT3-ko mice display age-dependent deficits in the Morris water maze as well as deficits in fear conditioning. Therefore, behavioural tasks that test the somatosensory ability of ZnT3-ko mice may be confounded by processes such as learning and memory. In order to minimize involvement of the hippocampal and amygdaloid systems in our present study, we developed a novel whisker-mediated texture discrimination task to test the sensitivity of the whisker-sensory system. We found that ZnT3-ko mice were significantly impaired in the texture discrimination task compared to wild-type controls. Wild-type mice were able to discriminate between rough and smooth textures separated by 25 μm in mean grit size while ZnT3-ko mice were not able to make the discrimination with a difference of less than 300 μm. We tested mice that were both 3 months of age and greater than 6 months of age, and found that age did not affect the level of impairment observed in ZnT3-ko mice. The results from our study suggest that vesicular zinc may be important in regulating the sensitivity with which the animal processes sensory information.

Title: Circuit requirements for spatial touch localization

Authors: *C. HUANG, A. RESNIK, T. CELIKEL
USC, LOS ANGELES, CA

Abstract: Anatomical extraction of cortical columns (Hutson & Masterton, 1986) or targeted down-regulation of the electrical activity in the supragranular layers of individual cortical

columns in the primary somatosensory cortex (Laudenklos et al, 2005) impair haptic object localization on the gap-crossing task. However, the neural computation that is responsible for localization of touch is not known.
To address the minimal circuit requirements for successful spatial localization we intracellularly recorded sub- and suprathreshold activity from excitatory neurons in the supragranular layers (L2/3) of the barrel cortex, and show that individual L2/3 neurons' subthreshold responses contain as much information about stimulus location (i.e. which whisker is being deflected) as the stimulus entropy. When the action potential (AP) is generated there was a significant information loss (1.86±0.17 vs. 0.36±0.14 bit, $p<0.001$) which occured across all membrane states. To determine whether local computation in L2/3 can rescue the lost information, we developed a 2-layer network model where distribution and identity of neurons were determined after reconstructing the canonical cortical column in the somatosensory cortex in soma resolution (see Ye, Huang, Celikel poster). Simulations on this computational column showed that although APs from single L2/3 neurons are not information rich (0.28±0.15 bit), similar to observations in the biological column above, all the information about the stimulus can be successfully recovered by integrating responses from a pool of 8-20 local L2/3 neurons. Contribution of each neuron to the information recovery depends on the slope of their excitatory postsynaptic potential (EPSP) and their AP threshold, the membrane potential at which they generated an AP. Neurons whose AP thresholds are hyperpolarized carry significantly more information about the stimulus (0.33±0.16 vs 0.21±0.11 bit; -56 to -54 vs -54 to -52 mV respectively). Accordingly faster rise in EPSP slope is positively correlated with the information content of the neuron. These results suggest that subthreshold responses of single L2/3 neurons in the barrel cortex have complete information about the spatial localization of touch however, at the network level, a small but finite number of L2/3 neurons (<20) are required for computing object location. Interestingly contribution of individual neurons' to information recovery at the network level is not stochastic but depends on the rate with which they integrate the incoming synaptic information.

Title: Short latency contralateral inhibition identified in single motor units in human

Authors: *U. YAVUZ[1], F. NEGRO[1], S. S. GEERTSEN[2], J. B. NIELSEN[2], D. FARINA[1], N. MRACHACZ-KERSTING[3]
[1]Dept. of Neurorehabilitation Engin., Univ. Med. Ctr. Göttingen, Goettingen, Germany; [2]Dept. of Exercise and Sport Sci., Univ. of Copenhagen, Copenhagen, Denmark; [3]Ctr. for Sensory-Motor Interaction (SMI), Dept. of Hlth. Sci. and Technol., Aalborg Univ., Aalborg, Denmark

Abstract: In static and dynamic tasks a short latency (37-41 ms) inhibition of the contralateral Soleus (cSOL) muscle occurs following ipsilateral tibial nerve (iTN) stimulation [3, 4]. To gain further insights into the pathways that induce this response we have recently investigated the convergence with the disynaptic inhibitory pathway evoked by common peroneal stimulation on the contralateral side (cCPN) [1]. For such studies it is necessary to determine the exact timing of the responses in relation to the stimuli. Surface electromyography (sEMG) has limitations in this regard as it relies upon the occurrence of action potentials at a particular time in relation to the stimulus and a strong response can synchronize their timing thus distorting their onset [2]. The aim of the current study was to use the peristimulus frequencygram (PSF), a technique which illustrates the time course of the net input current to a motor neuron more accurately compared with sEMG, to study the time-course of the postsynaptic potential in cSOL motor neurons induced by the two stimuli (iTN and cCPN stimulation). Three subjects (age: 26-40 years) were seated in a chair with their cSOL contracted to 5-10% maximum. Bipolar Teflon® insulated silver wires (75 µm in core diameter) were inserted into the cSOL muscle. sEMG was recorded with bipolar electrodes from the same muscle. Three conditions were investigated and the stimuli were applied randomly: 1) iTN at 2×motor threshold, 2) cCPN at motor threshold, and 3) iTN+cCPN stimulation. Signals were recorded at 10 kHz for offline PSF and trigger averaged sEMG analysing. The onset of inhibition measured from trigger averaged sEMG was 44 ± 1.7 ms in the iTN stimulation, 48 ± 2.0 ms for cCPN stimulation, and 41 ± 1.7 ms for the iTN+cCPN condition. Six motor units were decomposed from the intramuscular EMG signals. The PSF showed that the iTN stimulation induced short latency contralateral inhibition on all cSOL motor units with an average latency of 42 ± 7 ms. The amount of inhibition (27.7 ± 10.5%) in the iTN+cCPN condition was above that found for the summation of the inhibition response in iTN (12.9 ± 7.6%) and cCPN (13.8± 2.8%) conditions for all motor units. This is the first study to show a significant change in the firing rate of single motor units of the cSOL following iTN stimulation. It further supports our previous finding that it is at least in part mediated via Ia inhibitory interneurons in the disynaptic reciprocal inhibitory pathway.

Title: Effect of chemosensory inputs into the pharynx on voluntary swallows in humans

Authors: *M. INOUE[1], Y. NAKAMURA[1], A. HATAKEYAMA[1], Y. KITADA[2]
[1]Div. of Dysphagia Rehabil., Niigata Univ., Niigata, Japan; [2]Morioka taste and swallowing research institute, Morioka, Japan

Abstract: Introduction: Ability to initiate repetitive voluntary swallowing varies even among healthy humans. In the previous study, we recorded voluntary swallows and showed that the number of swallows was increased with appropriate chemosensory inputs, e.g., activation of water receptors in the pharynx and larynx, which may compensate for difficulty in initiation of swallowing. The aim of this study was to investigate if the pattern of swallow-related electromyographic (EMG) burst in the suprahyoid muscles was also affected by the peripheral conditions. We hypothesized that the rising time (RT) of EMG burst was decreased with increasing the number of swallows in each subject.
Methods: Voluntary swallowing was recorded during infusion of fluid (distilled water [DW] or 0.3 M NaCl solution) into the pharynx at a very low rate in 18 healthy volunteers. DW and NaCl were used to activate and inhibit the water receptors. Swallowing intervals (SIs) were measured between the fourth and ninth swallows, In addition, using rectified suprahyoid EMG burst, the rising time (RT) defined as the time interval between the onset and peak and falling time (FT) defined as the time interval between the peak and offset were measured. Facilitatory effect (FE) for SI was calculated by subtraction of the SI of DW from that of NaCl. Similarly, FE for RT was also obtained. Means values of these variables were compared between DW and NaCl.
Results: SIs were significantly shorter during the infusion of DW than that of NaCl. RT was significantly shorter during the infusion of DW than that of NaCl solution while there was no significant difference in the FT between the conditions. There was a linear positive correlation between the conditions; the longer either the SI or RT with infusion of 0.3 M NaCl solution was,

the stronger the facilitation of swallowing by chemosensory
inputs was. While the percentage of facilitation of both the SI and RT exhibited great variation among the subjects, there was a linear correlation between them.
Conclusion: The present results suggest that not only SI but also RT represent individual potential to perform swallow.

Title: A quadrupedal postural controller with physiological sensor delays

Authors: *N. E. BUNDERSON[1], T. R. NICHOLS[2]
[2]Sch. of Applied Physiol., [1]Georgia Tech., Atlanta, GA

Abstract: Animals have a multi-layered control system which includes intrinsic viscoelasticity of muscle, and short and long latency neural feedback mechanisms. To what extent each of these contributes to postural stability is a matter of intense debate. We have developed a postural controller which takes into account actual biological complexities such as physiological time delays and redundant joints and actuators. By including the complexities we demonstrate a role for the multi-layered control observed in animals which is not evident in simplified models. We propose that the postural task can be divided into local (joint and limb) and global tasks and that control of these tasks is divided among biological layers of control.
The musculoskeletal model is comprised of a 6 degree of freedom trunk segment and four limbs. Each limb has 6 kinematic degrees of freedom and 31 muscles. The total force in each muscle is the sum of undelayed intrinsic forces, reflexive (20ms delay) forces, and control (60ms delay) forces. The intrinsic forces are modeled with a parallel spring and damper acting on the instantaneous change in muscle length and velocity. Reflexive forces are modeled with a similar parallel spring and damper acting on the delayed length and velocity values.
The control forces are the sum of constant background forces and delayed control forces. The delayed muscle control forces are calculated to minimize ground reaction force magnitudes and generalized coordinate accelerations of an internal model. The internal model is constructed from

delayed state information. The delayed muscle control forces must also result in a net force and torque acting on the internal model center of mass which is equivalent to that which would be produced by a virtual parallel spring damper attached to the internal model center of mass. The controller robustly stabilizes a model of a quadruped against postural perturbations. The model cannot stabilize against perturbations when any of the layers are removed and the mode of failure is different depending on which layer is removed suggesting different roles for each

layer.

Title: Neuromuscular recovery patterns following robotic gait training in spinal cord injury

Authors: *M. M. MIRBAGHERI[1,2], X. NIU[1,2], D. VAROQUI[1,2], M. KINDIG[2]
[1]Physcal Med. & Rehabil., Northwestern Univ., CHICAGO, IL; [2]Sensory Motor Performance Program, Rehabil. Inst. of Chicago, Chicago, IL

Abstract: Spasticity is a common consequence of spinal cord injury (SCI), affecting mobility and causing gait impairments. The therapeutic effects of robotic-assisted locomotor (LOKOMAT) training on the neuromuscular abnormality associated with spasticity were characterized in SCI subjects with incomplete motor function loss. LOKOMAT training was provided to subjects 1-hour per session, three days per week for four weeks, with up to 45 minutes of training per session. The neuromuscular properties of the ankle were then assessed using a joint perturbation device prior to and after 1, 2, and 4 weeks of training. A system identification technique was used to quantify the joint stiffness and separate it into intrinsic (muscular) and reflexive components. The modulation of these neuromuscular properties with joint angle was characterized over training time. Reflex stiffness increased slightly from full- to mid-plantarflexion and then increased sharply and reached a maximum between neutral position and mid-dorsiflexion, and then decreased thereafter. This modulation was quantified by a linear regression fit to the sharply increasing portion of the curve. Recovery patterns for the slope and intercept of this regression were classified using “growth mixture” modeling. The ability of baseline measures of walking capacity (gait speed, endurance, and mobility) to predict the slope and intercept recovery patterns was evaluated using logistic regression analysis.
Two distinct classes were observed. Class 1 subjects had initially higher reflex stiffness parameters (i.e., intercept and slope vs. ankle position) and reduced significantly over the training period. Class 2 subjects initially had lower reflex stiffness parameters and experienced minor reductions. Similar results were observed for the intrinsic stiffness intercept; however, intrinsic slope showed no significant improvement over training for either class. The results reveal that subjects with higher reflex intercept were correlated with lower walking capacity. These findings demonstrate that LOKOMAT training is effective in reducing reflex and intrinsic stiffness (which abnormally increase in SCI) and improving the abnormal modulation of reflexes over the ankle range-of-motion. Further, reflex abnormality contributes to walking impairment. Thus, LOKOMOAT training can be considered as effective interventions for improving neuromuscular function in SCI.

Title: Persistent inward currents and their role in spasticity

Authors: *S. NANDYALA, C. M. NIU, T. D. SANGER
USC, Los Angeles, CA

Abstract: Spasticity is a condition in which a person suffers from an abnormal, velocity-dependent tightness or stiffness in response to a passive stretch. While a clinical identification of the features of spasticity can be performed, the relationship between spasticity and the pathophysiological phenomena observed in the presence of spasticity remains unclear. One of these phenomena is the development of persistent inward currents which activate the spinal motoneurons to varying degrees. Due to the complexity involved in isolating the phenomena in vivo, the extent to which each of these these phenomena contributes to the production of spastic symptoms remains unknown. However, with advances in computing hardware and technologies, it is now possible to construct a biorealistic system which mimics the actual spinal motor loop using computational models of the required parts. Therefore, we set out to build a hardware system where we can systematically add in each of the phenomena found in the presence of spasticity and quantifiably determine the extent of their involvement. Our system is constructed using models of muscle fibers, muscle spindles, synapses, and spiking neurons. The baseline version of the system uses a regular spiking neuron model to mimic healthy motoneurons. The experimental version of the system uses a spiking neuron model modified to mimic the persistent inward currents (PICs) found in spastic motoneurons. Using the model, we simulated stretch reflexes at a single joint. The results show short-latency stretch reflexes that are abnormally enhanced in the presence of PICs. Analysis of the EMG onset as a function of speed of stretch shows good correspondence to known spasticity patterns as reported in (Levin et. al. 2000). Analysis of the reflex torque in response to a stretch also shows good correspondence to known spasticity patterns as reported in (Rymer et.al 1999). From this model, we conclude that PICs are sufficient to produce the EMG response to stretch as seen in spasticity. While this does not prove that PICs are responsible in vivo, it does suggest that PICs by themselves are sufficient to explain spasticity, and thus if found in patients with spasticity no other explanation would be required.

Title: Stretch reflex responses in the ankle plantarflexor muscles associated with locomotor adaptations to resisted walking

Authors: C. CHEUNG[1,3], *A. DOMINGO[2,3], L. BOUYER[4,5], T. LAM[1,3]
[1]Kinesiology, [2]Human Kinetics, Univ. British Columbia, Vancouver, BC, Canada; [3]Intl. Collaboration on Repair Discoveries (ICORD), Vancouver, BC, Canada; [4]Dept. de Réadaptation, Univ. Laval, Quebec City, QC, Canada; [5]Ctr. for interdisciplinary research in rehabilitation and social integration (CIRRIS), Quebec City, QC, Canada

Abstract: In order to respond appropriately to changes in the environment, the nervous system has to rapidly adapt its motor output. During walking, sensory feedback pathways play an important role in mediating such adaptations. We have previously shown that a Lokomat-applied velocity-dependent resistance against hip and knee flexion during walking results in an adaptive increase in hip and knee flexor muscle activity during swing. With sustained exposure to the resistance, after-effects in the form of high stepping can be observed. We have also observed increased plantarflexor activity at the end of stance with Lokomat-applied resistance. Such adaptive changes in muscle activity provide a means for understanding how changes in reflex gain may contribute to locomotor adaptations. Thus the purpose of this study was to determine if the there are changes in the strength of stretch reflex pathways from the ankle plantarflexors with the locomotor adaptations seen in resisted walking. Subjects performed multiple walking trials with and without resistance. A robotic gait device (Lokomat) was used to apply velocity dependent resistance against hip and knee motion. Plantarflexor stretch reflexes in the right ankle were elicited with a motorized ankle-foot orthosis (Noel et al., 2009) that applied 4-6 deg dorsiflexor stretches at 150-200 deg/s. Perturbations were timed to coincide with early and late stance (15 ± 5% and 52 ± 4% of the step cycle, respectively). Surface EMG was recorded from the right soleus, medial and lateral gastrocnemius, and tibialis anterior. For each subject, short-latency (35.5 ± 3.4 ms) reflex responses (mean amplitude) were identified by plotting the means of the perturbed and non-perturbed cycles, and analyzed by manually placing cursors. Lokomat-applied resistance against hip and knee movements during walking was associated with an increase in EMG activity in the ankle plantarflexors during late-stance but not during early stance. Rapid dorsiflexion stretch perturbations resulted in a clear stretch reflex response in plantarflexor muscles. During steps against resistance, however, the normalized amplitude of the stretch reflex response was suppressed compared to non-resisted steps. This was observed in the reflex ratios (resisted/baseline) for short latency reflex response elicited in the soleus during late stance (0.67 ± 0.21) as well as during early stance (0.72 ± 0.34). The suppression of stretch reflex responses during late stance was present despite an increase in the background EMG.

These results suggest that changes in the gain of peripheral feedback pathways may not contribute to the production of locomotor adaptations to resistance.

Title: Increased hip to ankle contribution during a challenging standing tracking task in people with multiple sclerosis

Authors: *M. C. CHUA[1], A. S. HYNGSTROM[2], A. V. NG[3], B. D. SCHMIT[1]
[1]Biomed. Engin., [2]Physical Therapy, [3]Exercise Sci., Marquette Univ., Milwaukee, WI

Abstract: This study demonstrated that people with MS increase hip contributions, and reduce ankle contributions to balance control during a standing arm tracking task, compared to healthy subjects. Although it is well-known that MS affects mobility by disrupting balance and gait, adaptations to control strategies for functional movements are not well described. A better understanding of changes in movement control in MS is important for designing therapies to counteract the effects of MS on movement.
Participants in this study included 10 individuals with MS and 10 neurologically intact subjects. All subjects were able to walk 6-10 meters comfortably at a self-selected pace and were 30-60 years old. Subjects tracked a moving target with their finger along a figure-eight trajectory that was projected on a large touchscreen. The movement of the target either increased linearly (ramp tracking) in frequency from 0.2 - 1.5 Hz over a period of 67 seconds, or maintained a steady speed (steady speed tracking) at seven different frequencies between 0.2 and 1.5 Hz. Motion capture cameras and two force plates were used to capture kinematic and kinetic data.
The MS subjects showed increased ratios of hip to ankle peak-to-peak (PP) moment, as well as hip to ankle PP angular range of motion during both ramp and steady speed tracking, compared to the control subjects. The maximum hip and ankle moments and angles also showed a negative correlation to increasing level of impairment, measured with the Berg Balance Score and 25 feet walk test.

This study demonstrates that people with MS use increased hip and reduced ankle control to maintain balance during a challenging standing tracking task. This altered hip-ankle strategy for maintaining balance in a challenging situation, which might be related to differences in impairment between the hip and ankle.

Title: Motor output is relatively resistant to global ischemia and recovers faster following reperfusion than sensory processing in Channelrhodopsin-2 transgenic mice.

Authors: *Y. XIE, S. CHEN, R. LIU, E. ANENBERG, T. MURPHY
Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Previously, we have developed an approach to directly probe neuronal excitability during the period beginning with induction of global ischemia and extending after reperfusion using transgenic mice expressing Channelrhodopsin-2 (ChR2). Within these ChR2 mice, we activate deep layer cortical neurons independent of synaptic or sensory stimulation. In the present study, we employed a motor mapping technique using ChR2 transgenic mice combined with electromyographic (EMG) recording to assess dynamic changes in motor output during 5 min of global ischemia and following reperfusion. For comparison, we simultaneously assessed sensory processing by electrically stimulating the forepaw and recording the electroencephalographic (EEG) signal in the somatosensory area and the ChR2 stimulation-evoked EEG response in the motor cortex representation. Consistent with our previously

reported findings using urethane anesthesia, in ketamine/xylazine anesthetized mice, neuronal excitability assessed by the ChR2 stimulation-evoked EEG responses was intact during the period of strong spontaneous EEG suppression, was depressed during ischemic depolarization and mostly recovered (96.3 ± 18.8% of pre-ischemia value, n=5) 10 min after reperfusion. In contrast, the decrease of the somatosensory-evoked potential coincided with the EEG suppression and the recovery was incomplete and delayed after reperfusion (27.8 ± 9.5% of pre-ischemic value at 90 min, n=5). Surprisingly, EMG responses evoked by the ChR2 stimulation in motor area showed significant recovery (51.0 ± 28.1% of pre-ischemic value, n=5) 15 min after reperfusion and further completely recovered to 97.8± 30.5% of pre-ischemic value 55 min after reperfusion. The present results confirmed our previous findings which defined a period where cortical neurons are excitable but synaptically silent after global ischemia using a different anesthesia (ketamine/xylazine) and temperature regulation (brain surface temperature was clamped to 36.5°C). Novel findings from our results demonstrate relatively reduced vulnerability of motor output compared to sensory processing following global ischemia and reperfusion. Differential sensitivity of sensory and motor processing to the effects of stroke may have implications for particular forms of rehabilitation that target these systems.

Title: Identifying neuromuscular control during low back stabilization: Simultaneously quantifying intrinsic properties and proprioceptive feedback

Authors: *P. DRUNEN[1], E. MAASWINKEL[2], F. C. T. VAN DER HELM[1], J. H. VAN DIEËN[2], R. HAPPEE[1]
[1]3mE, Delft Univ. of Technol., Delft, Netherlands; [2]Human Movement Sci., VU Univ. Amsterdam, Amsterdam, Netherlands

Abstract: Motor control deficits have been suggested as potential cause and/or effect of a-specific low-back pain and its recurrent behaviour. Therefore, the goal of this study was to identify motor control in low back stabilization by quantifying the intrinsic properties and

proprioceptive reflexes simultaneously. Most recent studies in low-back stabilization have focused either on intrinsic properties or on reflexes, by experimentally excluding one component or have lumped both components. However, changes in co-contraction could result in changes in proprioceptive reflexes and vice versa, making combined identification essential.
In fifteen healthy subjects, upper body sway was evoked using continuous anterior force disturbances (0.2-15 Hz, 35 N amplitude, 60 N preload) applied dorsally at T10 level, while the subjects performed a resist or relax task. Torso kinematics and reflexive muscle activation (sEMG) were evaluated using closed loop identification. Intrinsic and reflexive contributions to low-back stabilization were identified using a physiologically-based, neuromuscular model including intrinsic stiffness, intrinsic damping and inertia combined with sensory feedback from muscle spindles (position and velocity) and Golgi tendon organs (force).
Task dependency was found at low frequencies for both kinematics and reflexive back muscle activity (the resist task had reduced displacement and stronger reflex gains). The neuromuscular model was able to predict on average 84% of the kinematics and 36% of the sEMG measurements, while resulting parameter values were consistent over subjects. The methodology presented allows identification of low back motor control by quantifying the intrinsic properties and proprioceptive reflexes simultaneously. Therefore, this methodology has the potential to investigate motor control deficits in LBP patients in detail.

Title: Fatiguing to exhaustion affects spinal inhibitory mechanisms

Authors: *B. TAHAYORI[1], C. ACIKADA[2], R. F. CHAPMAN[1], D. KOCEJA[1]
[1]Indiana Univ., Bloomington, IN; [2]Hacettepe, Ankara, Turkey

Abstract: Exercised-induced fatigue causes a wide variety of central and peripheral changes in the neuromuscular system. Many neural mechanisms have been implicated during a fatiguing

task. These adaptations are thought occur as an adjustment to the failure of the muscular contraction ability. It is shown, for example that the H-reflex amplitude decreases during sustained submaximal contraction or at post-exercise the Hmax/Mmax ratio decreases. However, changes in the inhibitory circuits of the spinal cord after a prolonged bout of exercise have not been extensively examined. Here, we investigated two important inhibitory mechanisms in spinal circuits (post-activation depression (PAD) and recurrent inhibition-RI), after a heavy exercise to exhaustion (3 hour running) in 6 elite and well-trained runners. Using the method described by Pierrot-Deseilligny (1975) we measured the changes in the activity of the Renshaw cells. We also measured PRD throughout the soleus H-reflex recruitment curve, before and immediately after the termination of running. Subjects sat on a chair and placed both feet on a wedge and exerted an isometric pushing force equal to 10% of their maximum voluntary contraction, while monitoring their force output. The analysis showed that after the fatiguing exercise, the soleus recruitment curve was depressed and shifted to the right with the maximum H-reflex changing from 4.26 mV to 3.75mV (p=.028). In the PAD measurement, fatigue resulted in a decrease in the amount of depression observed. The PAD ratio (conditioned H to unconditioned H ration) was 78.1% which showed a statistically significant depression in H-Prime, while this value was 88.03% after fatigue which suggested no significant difference between the amplitude of the H reflex and the H' value. No significant change in recurrent inhibition was observed after fatigue (recurrent H being 30.42% pre-exercise vs. 31.08% post-exercise, p=0.31). Our results suggest that after a prolonged fatiguing exercise, the feedback loop of the alpha motoneurons do not change (which is an indication of postsynaptic events) while there is a decrease in post-activation depression. This release of inhibition might be a compensatory mechanism in response to the general depression of the H-reflex throughout the recruitment curve. It is also suggested that any change in reflex inhibition to motoneurons after fatigue is most probably due to presynaptic mechanisms and not to an autogenic (negative) feedback regulation.

Title: Capacity of young, middle-aged, and old subjects to improve steadiness during a cocontraction task by modulating Ia presynaptic inhibition

Authors: *J. GOULD, M. R. HOLMES, I. PEÑA-GONZÁLEZ, R. M. ENOKA
Integrative Physiol., Univ. of Colorado At Boulder, BOULDER, CO

Abstract: Old adults tend to perform motor tasks with a greater amount of antagonist muscle activation than young adults, but the reasons underlying this increased coactivation have yet to be identified (Hortobágyi and DeVita, 2006). When performing steady submaximal contractions, old adults accommodate changes in task demands by increasing the coactivation of agonist and antagonist muscles, whereas young adults rely on a strategy of modulating afferent feedback (Baudry et al., 2010). Old adults may prefer the feedforward coactivation strategy due to a decline in the function of the pathways that can provide feedback adjustments. The current study compared the changes in steadiness and the modulation of presynaptic inhibition of soleus Ia afferents in 11 young (24.5 ± 3 yrs, 6 women), 9 middle-aged (52.3 ± 8 yrs, 3 women), and 9 old adults (78.2 ± 4 yrs, 5 women) before and after a single session of practicing a cocontraction task. The task required subjects to sustain a target EMG amplitude for the plantarflexors while concurrently contracting (cocontracting) the dorsiflexors to reduce the net muscle torque about the ankle to zero. There was no difference in the maximal voluntary contraction (MVC) force for the plantarflexor muscles between young and middle-aged subjects, but MVC force was significantly less for old subjects ($P<0.05$). Younger subjects had a greater Hmax/Mmax ratio than middle-aged ($P<0.05$) and old subjects ($P<0.001$), whereas there was no significant difference between middle-aged and old adults. There were no differences in steadiness between groups during an initial cocontraction trial ($P=0.713$). The main finding of the study was that young adults were able to improve steadiness by ~19% ($P<0.001$) during the 50-min practice session, whereas there was no change for the middle-aged adults, and old adults became less steady by ~15% ($P<0.05$). Furthermore, the improvement in steadiness by young adults was accompanied by a significant reduction in the amount of Ia presynaptic inhibition, as indexed by D1 inhibition ($P<0.01$). Conversely, the other two groups exhibited no change in Ia presynaptic inhibition after practicing the cocontraction task. Rather, MVC force declined significantly for middle-aged (17%) and old (20%) groups following the cocontraction practice, whereas there was no significant difference in MVC force for the young adults. The findings indicated that young adults were able to improve steadiness with practice of a cocontraction task by modulating afferent feedback, whereas middle-aged and old adults were not able to improve steadiness despite no significant strength differences between young and middle-aged adults.

Title: Crossed-spinal modulation of the soleus H-reflex: The effects of age and physical activity.

Authors: *R. A. RYDER, K. KITANO, D. M. KOCEJA
Indiana Univ., Bloomington, IN

Abstract: A growing body of literature has associated participation in physical activity with higher levels of both physical and mental health during the aging process. One understudied mechanism in neural aging research is the role of physical activity in maintaining or restoring spinal cord reflex function, in particular the impact of physical activity on crossed-spinal reflexes and bilateral lower limb coordination during aging. Therefore, the purpose of this study was to examine the time-course modulation of the soleus H-reflex following a conditioning stimulation from the contralateral common peroneal nerve in both sedentary and highly physically active young and elderly subjects. Data was collected on 20 subjects who were divided into one of four groups: 1) physically active young subjects ages 20-35 (n=5), 2) sedentary young subjects ages 20-35 (n=5), 3) physically active elderly subjects aged ≥65 (n=5), and 4) sedentary elderly subjects aged ≥ 65(n=5). Each subject's physical activity level was determined by their responses on the International Physical Activity Questionnaire. To assess crossed-spinal reflex modulation, conditioning stimuli were delivered to the common peroneal nerve at the fibular head of the left leg (200 Hz train, 20ms duration at 1.2x motor threshold). This was followed by test stimulation to the posterior tibal nerve at the popliteal fossa in the right leg to evoke a soleus H-reflex (the control amplitude of H-reflex was adjusted at 50% of the maximal H response). The following inter-stimulus intervals between the conditioning and the test stimuli were examined: control (H-reflex only), 25ms, 50ms, 75ms, 150ms, and 300ms. All testing was performed with the subjects in the prone position. A significant interaction was found between inter-stimulus interval and physical activity ($F= 3.34$, $p=.027$). Sedentary subjects, regardless of age, demonstrated a significant facilitation in the reflex at 25ms, 50ms, 75ms, and 150ms (by 9%, 32%, 31%, and 22% respectively) whereas physically active subjects show an inhibition at 25ms (9%) and maintain stable reflex amplitudes across all other tested inter-stimulus intervals. It is concluded that participation in physical activity appears to contribute to greater crossed-spinal reflex stability in both young and old subjects.

Title: Effect of an anti-spastic medication (Tizanidine) on velocity-dependent component of the ankle stiffness in spinal cord injury population

Authors: *D. VAROQUI[1,2], M. W. KINDIG[1], X. NIU[1,2], M. M. MIRBAGHERI[1,2]
[1]Sensory Motor Performance Program, Rehabil. Inst. of Chicago, Chicago, IL; [2]Dept. of Physical Med. and Rehabil., Northwestern Univ., Chicago, IL

Abstract: Two-thirds of spinal cord injury (SCI) patients present spasticity at one year after injury. A major health problem for SCI patients, spasticity limits mobility, affects ambulation and reduces independence in daily activities. Tizanidine is an alpha(2)-adrenoceptor agonist widely used to manage spasticity resulting from SCI. Clinical studies show that tizanidine is an effective anti-spasticity agent, but the mechanism by which the spasticity is reduced remains unclear. Typically, the benefits of tizanidine on spasticity are assessed by clinical assessments of muscle tone, e.g., Ashworth scale, which cannot quantify the effects of this medication on the ankle stiffness. The aim of this study was to quantify the effects of tizanidine on passive and velocity- mediated components of the stiffness at the ankle joint. Twenty-five incomplete chronic SCI participants with long-term spasticity were recruited for this study. Patients were instructed to take tizanidine for four weeks. Patients were assessed four times during the month: at the baseline (pre-medication), and 1-, 2- and 3- weeks after the first administration of medication. A joint stretching position-controlled device applied a series of triangular dorsi-flexion perturbations with a 40° amplitude, while subjects were instructed to maintain no tonic contraction (relaxed condition). Ramps were applied at low velocity (5°/s) and high velocity (100°/s). The resistance torque and the plantar-flexor and dorsi-flexor EMG activity were recorded during all stretches. The resistance torque measured in the 5°/s condition was assumed to measure the passive stiffness, as no reflex activity was evoked in any of the participants at this velocity, as verified by EMG. Velocity-dependent stiffness was computed by subtracting the passive torque from the torque recorded at the 100°/s velocity. From the torque-angle curves, the resistance torque at controlled angular positions, quasi-static stiffness, and the energy loss were calculated. Results showed that the tizanidine did not affect the passive stiffness. However, we observed a reduction of the velocity-dependent stiffness during the high-velocity stretches. This decrease is particularly observed in the dorsi-flexion direction, where the ankle plantar-flexor muscles were stretched. This velocity mediated stiffness reduction appears as early as one week after the first dose of medication. Reduction in velocity-dependent component, which is most if not all reflexive response, demonstrates therapeutic effects of tizanidine on reflex behavior.

Title: The effect of six weeks endurance training on postural control during full body perturbations

Authors: *H. HASSANLOUEI[1], D. FALLA[2,3], L. ARENDT-NIELSEN[4], U. KERSTING[4]
[1]Aalborg Univ., Aalborg, Denmark; [2]Dept. of Neurorehabilitation Engineering, Bernstein Focus Neurotechnology (BFNT) Göttingen, Bernstein Ctr. for Computat. Neuroscience, Georg-August Univ. of Göttingen, Göttingen, Germany, Göttingen, Germany; [3]Emergency and Intensive Care Medicine, Univ. Hosp. Göttingen, Göttingen, Germany, Pain Clinic, Ctr. for Anesthesiology, Emergency and Intensive Care Med., Göttinge, Germany; [4]Aalborg university, Aalborg, Denmark

Abstract: Muscle fatigue is an exercise-related decrease in the maximal voluntary force and is known to adversely affect postural control. This study examines whether six weeks of endurance training can minimize the effects of fatigue on postural control during dynamic postural perturbations. Twenty healthy volunteers participated in the study and were randomly assigned to either a 6-week endurance training program or a control group (no training). For the training group, exercise was performed on a bicycle ergometer 3 times per week. The load intensity ranged between 50 to 70% of the heart rate reserve and the duration of the sessions were between 20 and 45 min. Maximum voluntary contraction (MVC) of the knee extensors was assessed at baseline and on week 7. Furthermore, at baseline and on week 7, dynamic exercise was performed on a SRM bicycle which consisted of light cycling followed by a ramping protocol starting at 100 W with the workload increased by 15 W. min $^{-1}$ until exhaustion. Simultaneous measures of anterior-posterior (*Fy*) and medial-lateral (*Fx*) ground reaction forces were analyzed during full body perturbations performed before and after the high intensity exercise protocol. Subjects stood on a moveable platform which produced an 8 cm forward slide over 0.5 ms at random time points so that the subject could not anticipate the perturbation. Changes in the center of pressure were assessed from the onset of platform movement until 300 ms after completion of platform movement. Preliminary results indicate a significant increase in knee extension MVC post training for the training group (pre: 541.5 ± 123.8 N.m, post: 712.1 ± 119.6; $P<0.05$) but not for the control group (pre: 585.65 ± 161.2 N.m, post: 468.01 ± 45.82;

P>0.05). At baseline, fatigue induced an increase in the anterior-posterior (*Fx*) ground reaction forces during the perturbations in both groups (pre fatigue: 106.92 ± 43.66 mm; post fatigue: 127.20 ±59.19 mm; P<0.05). However for the training group the ground reaction forces were not altered by the fatiguing protocol when assessed at week 7 (pre-fatigue: 96.44 ± 37.82 mm; post fatigue: 100.46 mm; P>0.05). In conclusion, six weeks of endurance training improved the ability to control balance along the anterior-posterior axis in response to rapid full body postural perturbations in the presence of muscle fatigue.

Title: Long-latency reflexes of the upper limb are insensitive to skin stretch

Authors: *I. KURTZER
Neurosci. and Histology, New York Col. of Osteo. Med., Old Westbury, NY

Abstract: A growing body of evidence indicates that long-latency reflexes - the muscular responses occurring ≈50-100 ms after a limb displacement - depend on multiple neural pathways. SAII cutaneous afferents may provide a sensory source for long-latency reflexes (LLRs) since these receptors are excited by the change in skin strain which naturally accompanies joint displacement. Accordingly, LLRs would be augmented by skin stretch that is congruent with the direction of joint displacement and attenuated by incongruent skin stretch. In this preliminary study we tested whether LLRs of the upper limb utilize this relevance source of information. Three healthy subjects participated (all male, 26-30 yro). Surface muscle activity was obtained from major muscles spanning their elbow joint (brachioradialis & triceps lateral), shoulder joint (pectoralis major& posterior deltoid) and both joints (biceps brachii & triceps longus). A programmable robot (KINARM, BKiN Technolgies) allowed free movement of the arm in the horizontal plane and applied brief torque pulses to displace the elbow joint. Elbow flexion evoked LLRs from the arm's extensor muscles whereas elbow extension evoked LLRs from its flexor muscles. Another stimulus was a brief skin stretch via a light-weight solenoid. We attached the device in two different arm positions to create a skin stretch congruent with elbow extension or elbow flexion. Elbow displacement, skin stretch, and paired stimuli occurred in

random sequence. Efficacy of these stimuli was assayed by the grand mean of each subject's t-value and general trends were assayed by linear regression.
Similar to our earlier studies, elbow displacement evoked robust LLRs in all of the arm muscles (grand mean t = 7.7). We did not find that skin stretch congruent with elbow extension or flexion evoked a LLR in any arm muscle (grand mean t = −0.6). Moreover, the LLR during elbow displacement did not differ from the LLR during elbow displacement paired with congruent skin stretch (grand mean t = −0.2) or incongruent skin stretch (grand mean t = −0.2). A similar pattern emerged in the patterns of linear regression. LLRs during elbow displacement accurately predicted LLRs during elbow displacement paired with skin stretch ($r = 0.95$, $P < 0.01$). The prediction was not improved by including activity from the skin stretch condition ($r = 0.93$, $P < 0.01$) nor did skin stretch predict the residual activity after removing elbow displacement as a factor (partial $r = -0.1$, $P > .2$),
Despite the relevance of skin stretch to signal limb displacement and its utilization in the conscious appreciation of limb position, we found no evidence that skin stretch contributes to the arm's LLRs.

Title: Reorganization of heterogenic inhibitory force feedback between hindlimb extensors after both acute and chronic time points post spinal cord injury

Authors: *I. F. NIAZI[1], T. NICHOLS[1], A. RISING[2,3], L. LITTLE[3], S. MONDELLO[3], D. HOWLAND[2,3]

Abstract: One of the major clinical issues associated with spinal cord injury (SCI) in mammals is the lack of animal's ability to maintain balance and weight support. We are interested to know how do the neural networks in the lumbar spinal cord of mammals and their interactions with muscles changes after SCI that may interfere with balance control. We hypothesize that following SCI there is reorganization of the postural limb reflexes driven by load receptors. Heterogenic force feedback provides cross-joint and axis coupling (Nichols 1994). Also, as proposed earlier (Biewener and Daley 2007) the distal joints provide the main mechanical interface with the ground, while the proximal joints serve mainly to drive the movement. In control decerebrate animals there is a proximal to distal gradient in the strength of inhibitory force feedback among the limb muscles. In decerebrate animals with acute to chronic (2-20 weeks) lateralized T10 spinal cord injuries, this gradient is reversed with strong inhibition onto the gastrocnemius muscles. This reversal was seen in cats regardless of whether the cat required assistance with weight support and balance or could walk independently across a runway. In contrast, cats that received dorsal hemisections did not show this reversal. Thus, we propose that ventral/ventrolateral horn pathways in the spinal cord are important for regulating the distribution of intermuscular force feedback.

Title: The effect of age on responses to TIbial Nerve STIMULATION during walking

Authors: *S. R. HUNDZA, R. BRODIE, A. GAUR, D. COMMANDEUR, T. GIBNEY, M. D. KLIMSTRA
Univ. Victoria, Victoria, BC, Canada

Abstract: While walking can become limited or impaired with age, the specific changes in neural control across the adult lifespan that are associated with this behavioural change are not well understood. In young healthy subjects, studies have used muscle and cutaneous reflexes to probe the neural control of rhythmic locomotor tasks revealing characteristic reflex modulation patterns both within and between limbs. These stereotypical reflex responses are specifically sculpted to serve important regulatory functions during human locomotion such as assisting with obstacle avoidance during swing phase. In this way, cutaneous reflexes can be used as an indicator of neurological function during locomotion as well as to characterize deficits in neural control. To date, age-related differences in electrically-evoked cutaneous reflex responses during walking have not been investigated. Understanding age-related differences in cutaneous reflex control is vital given their putative functional relevance during walking for obstacle and trip avoidance. We have compared cutaneous reflex responses during locomotion in between young (18-30 yrs) and healthy older adults (>70 yrs). EMG recordings were made from limb and trunk muscles using a tethered surface EMG system. Reflexes were evoked with electrical stimulation (5 x 1 ms pulse @ 300Hz) to the distal tibial nerve at the ankle during walking on a treadmill. EMG during stimulation and control conditions (without stimulation) were averaged separately and subtracted for each phase of the walking cycle to yield a cutaneous reflex response. Additionally 3D motion analysis was performed to assess any kinematic changes associated with the tibial nerve stimulation. Preliminary analyses showed age-related differences in responses. This understanding may be useful to establish mechanisms of age-related neural changes and present potential markers for deterioration in functional ability related to fall risk.

Title: Technical considerations for gait analysis using wearable inertial measurement units.

Authors: *M. D. KLIMSTRA[1], R. CATER[2], S. MONSEES[3], K. GALLAGHER[3], N. LIVINGSTON[4], S. MACDONALD[5], G. MULLIGAN[3], D. COMMANDEUR[3], S. HUNDZA[3]
[2]Biol., [3]Exercise Science, Physical and Hlth. Educ., [4]CanAssist, [5]Psychology, [1]Univ. of Victoria, Victoria, BC, Canada

Abstract: When performing gait analysis clinicians and researchers must carefully consider their measurement tool, variable of interest as well as analysis technique. Each of these factors can alter the ability to accurately detect differences between gait conditions as well as clinical populations. Therefore the major aim of this study was to evaluate each of these factors across different experiments in multiple clinical populations. There are currently a number of instruments that can be used to measure gait events such as complex motion analysis systems, pressure sensing mats, pressure sensing insoles and wearable inertial measurement units (IMU). Each device has different capabilities with respect to ease of use, portability and set of measureable gait parameters. Additionally, it is very important to consider the reliability of a measurement device in collecting specific gait variables proven valuable at detecting gait deficiencies. As a prime example measures of gait variability have been recently used as a marker for gait performance, future mobility status, cognitive status, and falls. Therefore this suggests that a tool which is able to reliably detect subtle changes in gait variability would be clinical useful. As part I of this study we evaluated the use of an IMU, with a novel gyroscopic measurement algorithm, for measuring gait variability compared to a pressure sensing mat and video analysis. During this experiment we evaluated changes in stride time variability induced by wearing shoes with reduced stability (i.e. high heels) during walking. Also we determined changes in stride time variability for those with Parkinson's diseases as a result of engaging in a targeted exercise program. In Part II of this study we sought to further compare the IMU and pressure sensing walkway for measures of gait variability in an aging population during gait under varying cognitive demands. This data was analyzed for differences between groups when comparing the raw data as well and a novel "data residualization" technique. This analysis technique has potential to allow us to predict inter-individual differences in gait deficiencies beyond gross correlates such as age, gender and disease.

Title: Adaptation to asymmetric locomotor task

Authors: *S. YAKOVENKO, V. GRITSENKO
Human Performance, West Virginia Univ., Morgantown, WV

Abstract: The neural motor pathways evolved a combination of hierarchical and pluralistic control mechanisms to generate movements of increasing dexterity and complexity. Any movement including “simple” stereotypical locomotion is a product of interactions between descending and recursive feedback pathways that span several levels of the hierarchy. These interactions ensure integration of multiple objectives that ultimately result in the emergent sequence of muscle activations. While most studies focus on the specific pathways of the control hierarchy using predominantly a reductionist approach, the mechanisms of interactions between multiple pathways that require holistic and interdisciplinary methodology are not common. The main objective of this study is to describe the emergent properties of locomotor control and their task-dependent plasticity. We studied the interlimb interactions of spinal pathways that contribute to the control of human gait during adaptation to an asymmetric locomotion task. Subjects walked along curved paths that modified the speed of stepping of each leg. During this task, activity of 16 muscles was recorded using surface electromyography, and whole body 3D kinematics was recorded using an active-marker motion capture system. Additionally, soleus H-reflexes were evoked unilaterally multiple times during each step cycle. H-reflex modulation during the asymmetric locomotion task was compared with predictions of a biomechanical model of neural hierarchy. Specifically, we estimated optimal bilateral scaling of spinal contribution to the regulation of locomotor phases using the model and then tested these predictions experimentally during human gait by comparing evoked responses to transcranial magnetic stimulation and H-reflexes. The findings support the hypothesis that contralateral interactions modulate optimally sensory feedback gains, to drive the speed of stepping of each limb in an asymmetric locomotion task.

Title: Crossed-spinal influence on the human soleus H-reflex and efficiency of postural recovery from perturbation in young and elderly subjects.

Authors: *K. KITANO[1], R. A. RYDER[1,2], B. TAHAYORI[1,2], D. M. KOCEJA[1,2]
[1]Dept Kinesiology, [2]Program in Neurosci., Indiana Univ., Bloomington, IN

Abstract: The purpose of the study was to investigate a possible connection between crossed-spinal mechanisms in spinal reflexes and bilateral coordination in the lower limbs. Participants were recruited from two age groups; elderly (n=29, age: >65 yr) and young (n = 14, age: 21-30 yr). The H-reflex was evoked in the right soleus muscle and data were collected while subjects were in the prone position. The soleus H-reflex was conditioned through the common peroneal nerve (CPN) in the contralateral side. A train of 4 consecutive pulses was used for conditioning (1ms duration with 6ms interval for 20ms). Inter-stimulus intervals between conditioning and test stimulation were set at 25ms, 50ms, 75ms, 150ms, and 300ms. Intensities were adjusted to evoke 50% of Hmax for test stimulation and 1.2x motor threshold for conditioning stimulation. Efficiency of postural recovery was assessed by principle component analysis (PCA) of the center of pressure (COP). Subjects were perturbed during quiet standing by electrical stimulations applied to the tibial nerve either bilaterally or unilaterally. COP trajectories were analyzed for 1 sec from the timing of stimulation. For H-reflex modulation, a significant interaction was found in age group by latency ($F = 3.49$, $p < .05$). Soleus H-reflex amplitudes were significantly facilitated at 50ms and 75ms intervals in both age groups (by 15% and 17% in the elderly group and by 19% and 15% in the young group, respectively) while elderly subjects showed extended facilitation to 150ms (by 31%). For the efficiency of postural recovery, the first components from bilateral, right, and left perturbation were significantly lower in the elderly compared with the young group (.951 vs .987, .905 vs .961, and .876 vs .966 respectively). It is suggested that the facilitatory effect in H-reflex by the conditioning stimulation applied in the contralateral CPN may be associated with the crossed-spinal connection in the spinal cord which may be related to the bilateral coordination in motor behavior. Moreover, attenuated efficiency of the postural recovery measured by PCA in the elderly may be associated with extended facilitatory effects in the soleus H-reflex. Taken together, the present study demonstrated a possible relationship between efficiency in bilateral coordination and mechanism in crossed-spinal neural network.

Title: Stiffness of the Forelimb of the Decerebrate Cat

Authors: *R. S. MARTIN, T. BURKHOLDER, T. NICHOLS
Georgia Inst. of Technol., ATLANTA, GA

Abstract: The cat forelimb differs from the hindlimb both in anatomy and neural wiring. These differences manifest themselves in the diverse ways each is used during locomotion and in different postures. Studies of limb stiffness were performed in order to (i) evaluate the mechanical properties, (ii) validate the performance of computational models, and (iii) infer the unique reflex organization brought about by these dissimilarities in the limbs. Measurements of endpoint forces of both forelimbs were obtained in a pre-collicular decerebrate preparation using 2 robotic actuators mounted with force sensors. Each scapula was immobilized with a clamp and, while in isoflurane-anaesthetized (passive) and unanesthetized (active) states, recordings were taken, in a natural standing position and a crouched position (5 cm above natural standing), of the natural spontaneous activity of the limb. Each perturbation of the supporting surface was a 1 cm displacement in 16 directions in the sagittal plane and 2 in the medio-lateral plane. The results indicated that the greater stiffness component was within 10° of the limb axis in all positions and states. The limb demonstrated more stiffness in compression and more compliance in extension in the natural standing position, while exhibiting the opposite behavior in the crouched position. Further analysis revealed that the mechanical properties of the forelimb during postural maintenance cannot be described as spring-like. These results suggest a substantial asymmetry in inter-muscular reflex organization.

Title: Human neck reflex adaptation towards the frequency content of anterior-posterior torso perturbations

Authors: *R. HAPPEE[1], E. DE BRUIJN[1], A. SCHOUTEN[1,2], F. VAN DER HELM[1,2], P. FORBES[1]
[1]Fac. of Mechanical, Maritime & Materials Engin., Delft Univ. of Technol., Delft, Netherlands; [2]Univ. of Twente, Enschede, Netherlands

Abstract: Reflex modulation has been extensively reported during posture maintenance in response to task instructions, and to perturbation type, bandwidth and amplitude. For the head-neck system the modulation of the vestibulocollic (VCR) and cervicocollic (CCR) reflexes is essential to maintain upright head posture during unexpected disturbances. Previous studies have estimated that VCR and CCR contribute equally during perturbations in the sagittal plane; however, their modulation with respect to the properties of the disturbance remains unclear. This study seeks to establish how neck reflexes are modulated during perturbations with varying properties and how each reflex contributes to stabilization behavior. We hypothesized that VCR and CCR (a) modulate according to the perturbation bandwidth, (b) are unaffected by the perturbation amplitude and (c) increase when performing a visual acuity task.
Methods: Twelve subjects were perturbed via the torso while restrained in a seated position on a motion platform. The anterior-posterior perturbations varied in bandwidth from 0.3 Hz to a maximum frequency of 1.2, 2.0, 4.0 and 8.0 Hz, at three different amplitudes, and with eyes open and closed.
Results: Head kinematics and neck muscle EMG demonstrated significant ($P < 0.05$) changes due to bandwidth, which through modeling and closed loop identification were attributed to modulation of VCR and CCR gains. VCR and CCR demonstrated dominant contributions to stabilization during high (8.0 Hz) and low bandwidth (1.2 and 2.0 Hz) perturbations respectively, and equivalent contributions during mid bandwidth perturbations (4.0 Hz). However both were attenuated when perturbations exceeded the systems natural frequency (~2-3 Hz). Amplitude had an effect only for the lowest amplitude relative to other conditions attributed to thresholding properties of the semicircular canals. With eyes closed reflex gains decreased, attributed to the reduced ability to discriminate self-motion without vision.
Conclusions: To maintain head-upright posture adaptations of neck reflexes are observed to occur due to perturbation frequency and visual task conditions but not amplitude. Estimation of reflex contributions demonstrates that previous literature has underestimated the contribution of CCR, particularly during low frequency perturbations.

Title: Responsiveness of H- and T-reflexes of soleus muscle to presynaptic inhibition induced by a low frequency train of stimuli

Authors: *R. A. MEZZARANE[1,2], F. H. MAGALHÃES[2], V. M. CHAUD[2], L. A. ELIAS[2], A. F. KOHN[2]
[1]Sao Paulo, Brazil; [2]Biomed. Engin. Laboratory, EPUSP, PTC, Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: The differences between the responsiveness of mechanically (T) and electrically (H) evoked reflexes of the soleus (SO) muscle to different conditioning were addressed. Previous studies have shown that the T-reflex is less sensitive to presynaptic inhibition (PSI), induced by conditioning stimulation to the common peroneal nerve (CPN), as compared to H-reflex. Recently, it was reported that increased frequency of the conditioning stimulus (up to 1Hz) to the CPN reinforces the effect of PSI onto SO H-reflex. Here, the following hypotheses will be tested: 1) the delivery of a train of conditioning stimuli at low frequency will enhance PSI of the T-reflex to a similar extent as observed for the H-reflex; 2) these effects will be the same for both conditioning to test intervals: 15 ms (to induce D1 inhibition) and 100 ms (D2 inhibition). Nine subjects, aged 31.5 ± 6.5 y (mean ± STD), were seated in an armchair with the legs immobilized. The mechanical stimulus was a sine wave with 10 ms duration applied to the Achilles tendon through a vibratory device. The electrical stimulus was a rectangular pulse (1 ms duration) applied to the posterior tibial nerve (PTN). T- and H-reflexes were conditioned by either a "single" (1 ms duration) or a "train" of 7-10 conditioning stimuli applied at 1Hz to the neck of the fibula 15 or 100 ms before PTN stimulation. A 3-way ANOVA was used to detect differences and interactions among conditions. H-reflex was more responsive to a single conditioning stimulus than T-reflex ($P<0.05$). The train of stimuli induced a significant reduction in amplitude for both reflexes ($P<0.05$) compared to the "single" condition. There was no significant interaction between the factors "reflex" and "type of conditioning stimulus" ($P>0.05$), which indicates that the conditioning train reduced T and H-reflexes to a similar extent. Given the lower sensitiveness of T-reflex to "single" conditioning, these results suggest that the effectiveness of the train in reinforcing PSI was proportionally higher for the T-reflex, as

compared to H-reflex. No interaction between either “reflex” or “type of stimulus” and the factor “type of inhibition” (D1 or D2) was detected (P>0.05), suggesting that D1 and D2 are part of the same inhibitory pathway. One explanation for the increased PSI level in response to the train of stimuli is that the post activation depression in inhibitory interneurons interposed in the oligosynaptic pathway could, as a final result, lead to a facilitation of PSI in both reflexes. The proportional higher effect for T-reflex might be explained by a possible less saturated PSI effect due to interaction between afferent volleys (bursts of firing) and mechanisms of PSI.

Title: The effect of cycling speed on control of knee extensor and flexor muscles in bicycling.

Authors: *J. LACZKO[1,2], P. KATONA[2]
[1]PPKE Fac. of Information Technol., Budapest, Hungary; [2]Fac. of Physical Educ. and Sport Sci., Semmelweis Univ., Budapest, Hungary

Abstract: Introduction: Investigating electrical muscle activities (EMG) of healthy persons’ during cycling is used to build functional electrical stimulation (FES) patterns for spinal cord injured (SCI) people. If the velocity of FES cycling is planned to be increased than how the stimulation of knee muscles should be changed? If muscle activities of healthy individuals are known than similar activity patterns should be planned for people with paralyzed limbs. As cycling velocity increases, the electrical activities of quadriceps and hamstring muscles increase, but it is a question how the control of flexor-extensor muscle pairs is changing and whether the rate of change of activities differs for the 2 muscle groups?
Methods: Surface EMGs of quadriceps and hamstrings muscle groups were measured for 41 healthy subjects’ (16-33 years aged) with the ZEBRIS movement analyzing system during cycling on a recumbent stationary bike equipped to apply 8 pedal resistance. Cycling was

executed with 2 velocities (about 45 and 60 rpm) and against 3 resistance (gear 1, 5, 8). The sampling frequency of EMG was 1000 Hz. Filtered (Butterworth) and smoothed (RMS) data were averaged across time. Muscle activities in the 2 speed conditions were given by the mean EMG amplitudes for each muscle for each resistance condition. A ratio was computed (mean EMG in fast cycling divided by mean EMG in slow cycling) to show change in EMGs as a result of speed change. The difference in ratios obtained for the 2 muscles was tested with Student's T-test. Correlation between the average time of pedaling cycles (PT) and mean EMG (across subjects, cycles, and muscles) was computed for each resistance condition.
Result: The effect of speed change is significantly higher for hamstrings than for quadriceps (quadriceps ratio: 1,307; hamstrings ratio: 1,477; p=0,0264) when cycling with medium resistance (gear 5). Correlation data shows that if pedal resistance is increasing than the correlation between mean PT and mean EMG values is stronger (gear 1: r=-0,297; gear 5: r=-0,504; gear8: r=-0,495).
Conclusion: The cycling movement is mainly the result of quadriceps' activity. The hamstrings is responsible for fine control. As the speed increases the activity of both muscle groups is increasing but the activity of the hamstrings is increasing relatively more than that of the quadriceps. We assume that while faster motion needs more muscle force it requires enhanced neural control. To increase pedaling velocity one must increase both muscle groups' stimulation level, but at different rate. We suppose that as a reflex process the neural stimulation of the hamstrings increases more to ensure proper regulation of cycling movements.

Title: The effects of intrinsic musculoskeletal properties of the frog-hind limb during a spinal wipe reflex under varying force fields: A simulation study

Authors: *A. RAMAKRISHNAN[1], S. F. GISZTER[2]
[1]Drexel Univ., PHILADELPHIA, PA; [2]Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: We believe that the way the spinal cord constructs flexible reflex actions is by using a limited set of motor primitives. Using sensory information and central estimation of state, we believe that these motor primitives are modulated in amplitude and time to achieve the required motor function. Motor primitives and muscle synergies have been identified in many studies using animal and human subjects.
An adult spinalized bullfrog (Rana catesbeiana) can execute a targeted hind-limb wipe reflex in response to noxious stimuli. This movement is composed of feed-forward and feed-back aspects that enable the frog to cope with multitude of on-line (during motion) interactions with the environment like a physical obstacle, viscous liquid, etc. We reported that there is a fine tuning of motor patterns during a wipe based on the initial limb configuration in the workspace and collisions (Kargo 2000, 2008, 2010). However, in Richardson, 2005, robotic perturbations of the frog hindlimb during a wipe failed to elicit any motor pattern change and the limb reached the target zone after a brief deviation in its path. This was attributed to the stabilizing role of intrinsic musculoskeletal properties. What are the limits of this 'preflex'?
In this study, we explore the limits of correction with intrinsic musculoskeletal properties under different physical conditions. We use a 3-dimensional 5 degree of freedom, 21 muscle actuated frog hindlimb model in OpenSim (Stanford, CA). Simulations reproduce a typical wipe reflex when driven by a primitive based framework for muscle activations. We have also incorporated a feedback layer that can reorganize motor commands (but not employed here). We first explore force perturbation experiments. We iterate force pulses in wipes from different starting positions in the workspace. Using the primitive-based wipe as a drive template, we subjected the limb to low and high force perturbations during the initial period of the wipe, driven feedforward (with no corrections as seen in Richardson). The behavior of the model solely depends on the active muscle contractions and the viscoelastic properties of the system. The simulated trajectories suggest that although the ankle trajectories tend to converge towards the target portion from a few points in the workspace, they fail to converge from a majority of the workspace points. This fit with our initial expectation that the behavior of a wipe is different at different starting limb configuration and this is most likely due to the fine-tuning of the motor commands using the feedback.

Title: Nociceptive withdrawal response in intact, unanaesthetized rats

Authors: C. FRIDLEY, M. SEAMON, L. WYATT, B. RIFE, *C. L. CLELAND
Biol., James Madison Univ., HARRISONBURG, VA

Abstract: The nociceptive withdrawal reflex (NWR) results in an animal withdrawing a limb from a potentially tissue damaging stimulus. Previous studies revealed that withdrawal responses follow one of two alternative patterns for spatial integration--the continuous or categorical patterns. The continuous model corresponds to a continuous change in response direction with a continuous change in stimulus location, allowing for a more appropriate movement away from a stimulus. In contrast, the categorical model corresponds to a movement that occurs in a limited number of preferred directions. In spinalized animals, previous research on the tail and hind leg in our laboratory supported the categorical model. While research involving spinalized mammals provides important information about spatial integration in the spinal cord, it fails to address the influence of supraspinal pathways. However, there have been few studies of the NWR in intact animals and none that evaluated the NWR of the foot in intact, unanesthetized animals. The goal of this study was to explore the spatial integration of the NWR in the hind-limb of intact, unanaesthetized rats. Rats were gently restrained horizontally in an acrylic box placed on glass. Heat stimuli were applied to 8 diverse locations on the foot with a laser. The resulting movement of the hind-limb was recorded with one or two, high speed (500 fps), video cameras. The rat typically responded with extension of the lower leg that lifted the body upward. Subsequently the rat rapidly moved its foot upward in either the anterior or postererior direction. Most commonly the initial response was lateral-posterior but then rapidly (<20ms) transformed into an anterior movement. Neither response direction nor response magnitude depended on stimulus location. These preliminary results suggest that the rat chooses between only two movements, although up to nine different locations were stimulated., supporting a categorical strategy for the foot NWR in intact, unanesthetized rats.

Title: Task dependent changes to hindlimb impedance in the decerebrate cat

Authors: *C. TUTHILL[1], T. NICHOLS[2]
[2]Sch. of Applied Physiol., [1]Georgia Inst. of Technol., ATLANTA, GA

Abstract: Prior investigations have shown that the patterns of heterogenic force feedback are altered in a task dependent fashion in the decerebrate cat (Tuthill and Nichols, SFN 2009). We found that inhibitory feedback between gastrocnemius and flexor hallucis longus was increased during downhill tasks. Our initial study to determine the impact of these changes on total limb impedance suggested that the directional organization of stiffness was altered rather than overall limb stiffness (Tuthill et al., SFN 2010). In an effort to reconcile these findings we have focused our attention to the modulation of limb impedance along the major axis of the leg.
Precollicular decerebrate cats were implanted with EMG electrodes and given a bilateral labyrinthectomy. The cats were mounted in a stereotaxic frame and secured at the pelvis such that the hip joint was allowed to rotate but not translate. The hindlimbs of were attached to robotic manipulators equipped with 6-axis force/torque sensors. These robots provided 1 cm perturbations directed along the hip-toe axis. Background force was modulated by electrically stimulating the contralateral tibial nerve evoking a cross-extension reflex response. Head pitches of +/- 20 degrees were used to simulate downhill and uphill conditions (Gottschall and Nichols, Phil. Trans. R. Soc. B 2011).
With this technique of measuring limb impedance, we found that stiffness about the major axis of the leg is decreased in the downhill condition as compared to level. This finding is statically significant when the results are grouped by background force in 5 N bins; however, this difference is lost when using the mean over the entire range of background forces which accounts for the contradiction between this study and the results presented previously.

Title: Is motor equivalence during reaching observable at the muscle level?

Authors: D. J. S. MATTOS[1], *J. P. SCHOLZ[2], J. KUHL[3], M. L. LATASH[4]
[1]Biomechanics and Movement Sci., [3]Biol., [2]Univ. Delaware, Newark, DE; [4]Kinesiology, Pennsylvania State Univ., University Park, PA

Abstract: Motor equivalence is defined as the ability to accomplish the same task using different effectors or in the presence of a perturbation. This idea reinforces the notion of synergy where elemental variables at different levels of analysis (e.g. muscles, joints) are organized to stabilize a performance variable of interest. A previous study showed that successful reaches where achieved by using different, motor equivalent joint configurations when the elbow joint was perturbed. The current experiment investigated whether a similar signature of motor equivalence was evident at the level of muscle synergies and whether motor equivalence differed during different phases of the reach.
Electromyography (EMG) of 15 arm/scapula muscles were acquired in 10 healthy individuals who reached to insert a pointer into a cylindrical target requiring position and orientation control. Arm perturbations were continuously provided by an elastic band placed across the elbow on trials randomized with non-perturbed reaches. Subjects were unable to predict whether a trial was to be perturbed. A smaller number of couplings (M-modes) of the 15 muscles were identified using principal component analysis of similar arm movements in a different task. EMGs from the main task were converted to M-modes and the relationship between small changes in M-modes and changes in pointer position/orientation (i.e., Jacobian) were estimated using regression analysis. Differences in the 5 M-mode configurations between perturbed and non-perturbed reaches (ΔM-mode) were projected into the null space (ME component) and range space (Non-ME component) of the Jacobian, and their lengths of projection computed. A repeated measures ANOVA tested the effect of performance variable (position *vs.* orientation), phase (pre-perturbation, 50-ms post-perturbation, 51-100-ms Post-Pert, and >100-ms Post-Pert), and component (ME *vs.* Non-ME)**.**
The ME component was significantly greater than the Non-ME component at all phases ($p<0.05$) and increased more than Non-ME during the first 100-ms post-perturbation ($p<0.05$), regardless of the performance variable ($p>0.28$).
The similarity of the effects of the perturbation on the relative amount of ME and Non-ME is not a trivial result. It suggests that muscle activations are organized into a synergy stabilizing not individual joint rotations but the endpoint trajectory. This result questions the idea of a hierarchy of synergies. It is more compatible with the view that motor elements at all levels of analysis are united into synergies stabilizing the ultimate task-related variables, not intermediate variables within the assumed hierarchy.

Title: Impaired spinal presynaptic mechanisms in patients with pure hereditary spastic paraparesis

Authors: *J.-C. LAMY[1], D. MAZEVET[2], A. DURR[3], R. KATZ[2]
[1]CESEM CNRS UMR8194 Univ. Paris Descartes, PARIS, France; [2]UPMC Univ. Paris 06, Er6, Physical Med. and Rehabil. Department, GHU Pitié-Salpêtrière, PARIS, France; [3]CRICM, UPMC, INSERM UMR_S975, CNRS UMR_7225, Genet. Department, GHU Pitié-Salpêtrière, PARIS, France

Abstract: Pure (or "uncomplicated") hereditary spastic paraplegias are characterized by the appearance of progressive spasticity and paraparesis in the lower limbs with usually no spasticity in the upper extremities. In the present series of experiments, we focused on the study of presynaptic mechanisms acting at Ia fibre - alpha motoneurone synapse since a decrease of their activity would increase the stretch-induced Ia volley in firing motoneurones and might therefore be responsible for stretch reflex exaggeration. Presynaptic inhibition of Ia terminals and post-activation at Ia fibre - α motoneurone synapse were determined in both lower and upper extremities in 18 patients with pure hereditary spastic paraplegias (belonging to 17 different families), including 8 due to Spastin (SPG4) mutations and 18 age-matched healthy participants. All patients exhibited spasticity in the legs with no symptoms in the arms. In the lower limbs, both presynaptic Ia inhibition and post-activation depression of the soleus motoneurones were strongly reduced with respect to healthy subjects. In addition, in striking contrast with our expectations, we also found a significant reduction of both presynaptic Ia inhibition and post-activation depression of the Flexor Carpi Radialis motoneurones in patients in comparison with healthy participants despite the absence of clinical abnormalities in the arms. At both cervical and lumbar spinal cord, presynaptic mechanisms were less altered in SPG4 mutation carriers

with respect to non-SPG4 mutation carriers. Moreover, baclofen therapy administrated orally strongly depressed both soleus and FCR Hmax/Mmax ratios. These findings are in accordance with post-mortem pathological studies which have described the pattern of damage seen in hereditary spastic paraplegias as a 'dying-back' central axonopathy in which the ascending (sensory) and descending (corticospinal) tracts in the spinal cord degenerate progressively throughout the nevraxis, starting from their terminal portions and then proceeding towards the cell body. Interestingly, the intermediate pattern of SPG4 patients compared to others SPGs points out a different underlying mechanism.

Title: The effect of age on responses to superficial Peroneal cutaneous stimulation during walking

Authors: *R. BRODIE, D. COMMANDEUR, S. HUNDZA, T. GIBNEY, A. GAUR, M. KLIMSTRA
Sch. of Exercise Science, Physical & Hlth. Educ., Univ. of Victoria, Victoria, BC, Canada

Abstract: Age-related changes in human biomechanics and motor control quantifiably alter locomotor activities throughout the lifespan. For example, ageing is related to differences in the pattern of muscle activity and joint torque during walking as well as changes in reflex sensitivity during posture and locomotion. Combined with a reduction of muscle strength and power which occurs in a non-uniform manner throughout the body, these alterations make it important to determine if the underlying neural mechanisms which produce a stable gait are commensurately altered.
Studies of reflexes have proven invaluable for understanding functional responses to sensory stimulation during locomotion, as well as to characterize deficits in control. For example, in healthy young subjects, it has been observed that reflex responses result in coordinated neural and mechanical outcomes that serve important regulatory functions during human locomotion.

Specifically, reflexes originating from the cutaneous afferents of the superficial peroneal nerve (SPn) have been shown to assist with obstacle avoidance during the swing phase of walking. While there has been some research on muscle afferent reflexes in the elderly indicating changes in central control that result in altered neural and mechanical responses to perturbations, there is no known research quantifying neuromechanical reflex responses to cutaneous electrical stimulation in older adults.
In the present study, cutaneous reflexes were evoked across the gait cycle through stimulation of the superficial peroneal (SP) nerve. Reflex responses were compared between young adults (19-40) and older adults (70+) with subtracted, normalized EMG responses and alterations in kinematics of the lower limb. Overall, the study of reflex responses during locomotor activities in the elderly may be useful to establish mechanisms of age related neuromechanical changes and present potential markers for deterioration in functional ability related to fall risk.

Title: Modulation of muscular and interneuronal activity by afferent stimuli during locomotor activity in the spinal feline

Authors: *D. P. KOWALSKI[1,2], M. A. LEMAY[3]
[1]Neurobio. and Anat., Drexel Univ. Coll. of Med., Philadelphia, PA; [2]Sch. of Biomed. Engin., Drexel Univ., Philadelphia, PA; [3]Dept. of Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: Following spinal cord injury, the lumbar locomotor circuitry controls locomotor movements in the hindlimbs and its output is modulated by afferent input. It has been shown that transmission in the afferent pathways to the locomotor centers is altered with training following complete transection. We investigated gait-related modulation in the medial-plantar tibial nerve reflex, a polysynaptic cutaneous reflex from the branch of the nerve innervating the foot pad, in

two groups of animals with a complete thoracic transection: locomotor trained and untrained. The trained animals were followed for >20 weeks, and the modulation in the reflex during treadmill walking was measured. The untrained animals were used to measure changes in the activity of both lumbar interneurons and muscles with nerve stimulation applied during air-stepping in a terminal experiment.
In the trained group, we found that the reflex modulated with the phase of gait. Defining reflex activation/depression of the motor output as the region of EMG activity that fell outside the 95% C.I. of the background activity following single pulse stimulus delivered to the nerve, we found that flexor activity was enhanced by the reflex (10-35msec post-stimulus), while extensor activity could be both depressed (10-35msec) and enhanced (40-60msec). With further training, we found that tibial-evoked reflexes appeared during a larger percentage of the step cycle. We also found that stimulating the tibial nerve using long trains of stimuli (200 ms, 100Hz) evoked mainly flexor-related activity, rather than the mixed flexor and extensor reflex-evoked responses with single pulses.
In the acute experiments with untrained spinal animals, we found the same enhancement of the flexor activity and depression of the extensor activity following tibial stimulation. We observed single-unit activity that showed a phase-dependent increase or decrease in firing (10-25msec post-stimulus) following nerve stimulation. Our evidence confirms that gait-dependent modulation of muscle activity in response to afferent input is programmed at the level of the cord and that reflex circuits are potentiated following step-training.

Title: Motor point stimulation as a tool to investigate neural circuits

Authors: *K. MASANI, D. G. SAYENKO
Toronto Rehab Inst., Toronto, ON, Canada

Abstract: Neuromuscular electrical stimulation (NMES) has been successfully used to investigate and/or modify neural circuits. When NMES is applied, the "motor point (MP)", which is the most sensitive location to the electrical stimulation and is supposed to represent the neuromuscular junction between a motor nerve and a muscle fibre, is stimulated. It is

hypothesized that, when the MP is stimulated, the motor axon is selectively activated without activating the Ia-afferents since the neuromuscular junction is connected only to the motor axon. Peripheral nerve stimulation is often used to investigate the spinal or central neural circuits (e.g., H-reflex test using the tibial posterior nerve stimulation), where selective stimulation of motor axons has been attempted to induce the antidromic firing of the motor axon by using a very short stimulation pulse width. However, even with a short stimulation pulse width, the Ia-afferent stimulation is inevitable especially with a high stimulation intensity. MP stimulation can be a good tool to achieve selective stimulation of the motor axon. The purpose of this study was to investigate whether the MP stimulation can successfully induce the antidromic firing of the motor axon without activating the Ia-afferent nerves. The subjects were seated on a chair with a torque sensor measuring the ankle plantarflexion torque. The MP of the soleus was stimulated using a pair of strap electrodes. As the result, with the stimulation intensity increment, the M-wave increased and became plateau at approximately 60 mA. There was no H-wave seen at the corresponding latency, while an F-wave occasionally appeared without changes its size during the increment of the stimulation intensity. This result suggests that the MP stimulation activates the motor axon while not activating the Ia-afferent nerve. Further, when tibial posterior nerve stimulation was applied at various inter-stimulus intervals, the H-wave was strongly inhibited with inter-stimulus interval below 200 ms. This suggests that the MP stimulation evoked the antidromic firing that caused the strong inhibition to the H-wave, although the mechanism of this inhibition is not clear. The recurrent inhibition induced by the antidromic firing is a candidate mechanism for this finding. However, the period of the recurrent inhibition is less than 50 ms and thus does not account for the long lasting inhibition to the H-wave. It is concluded that the MP stimulation selectively produces antidromic firing of the motor axon without activating the Ia-afferent nerve. As such, we believe that the MP stimulation can be a useful tool to investigate the neural circuits.

Title: Characterization of motor unit activity in human lumbar multifidus: Evidence of self-sustained firing in motoneurons

Authors: L. R. LOTHE[1,2], T. J. L. RAVEN[1], *T. EKEN[1]
[1]Dept. of Anaesthesiology - Ulleval, Oslo Univ. Hosp., Oslo, Norway; [2]Univ. of Oslo, Oslo, Norway

Abstract: The underlying neurophysiology of low back pain is poorly understood. We have characterized motor unit firing activity in the lumbar multifidus muscle in healthy subjects as a reference before studying low back pain patients.
Three 50 μm diameter Teflon-insulated platinum/iridium wires were implanted in the deepest part of lumbar multifidus at L4 spinal level in 11 subjects (10 bilateral, 1 unilateral) using ultrasound guidance. EMG activity was recorded differentially during unhindered standing and during voluntary force production while standing in slight forward flexion. Individual motor units were identified using Spike2 software and analyzed with regard to instantaneous firing frequency, alternation of activity between units, and cross correlation between smoothed firing rates for concurrently active units. The common drive coefficient (CDC) was defined as the maximum value of the cross correlogram lying within 0±50 ms. Results are given as medians with 25th and 75th percentiles.
Total recording time in each subject was at least 20 minutes. Median firing frequency in 84 units from 9 subjects (7 males, 2 females; age 25 yrs (range 20-40)) was 7.4 Hz (6.2-8.7) for spontaneous activity, and 7.4 Hz (6.4-8.8) for voluntary activity. Cross correlograms from 97 unit pairs with median recording duration of 21.6 sec (range 4-793) showed a CDC in spontaneous activity of 0.48 (0.35-0.60) for ipsilateral units and 0.42 (0.22-0.55) for contralateral units. In voluntary activity, CDC was 0.28 (0.18-0.34) for ipsilateral units and 0.22 (0.16-0.31) for contralateral units. CDC in spontaneous activity was significantly higher than in voluntary activity ($P<0.005$; Wilcoxon rank-sum test) both ipsi- and contralaterally. In multi-unit recordings using one tonically active motor unit as a reference to monitor common synaptic drive, we found that slight postural changes could recruit new units to prolonged firing while the reference unit remained in its initial firing-frequency range. Similarly, after a period of concurrent firing one unit would stop firing while another simultaneously active unit continued to fire in its initial range.
We interpret our findings as evidence of self-sustained firing properties in motoneurons projecting to lumbar multifidus muscles in humans. Self-sustained firing would enable motoneurons to fire action potentials at a steady frequency for a sustained period of time, generating stable long-lasting muscle contractions. Further studies are needed in order to determine if disturbance in this activity might contribute to low back pain.

Title: Error correction for EMG decomposition algorithms

Authors: *J. C. KLINE[1,2], S. H. NAWAB[1,3,2], C. J. DE LUCA[1,2,3,4]
[1]NeuroMuscular Res. Ctr., [2]Dept. of Biomed. Engin., [3]Dept. of Electrical and Computer Engin., [4]Dept. of Neurol., Boston Univ., Boston, MA

Abstract: The electromyographic (EMG) signal consists of motor unit action potentials superimposed with each other and varying amounts of noise. Decomposing this signal into individual trains of motor unit firings is a process inherently probabilistic - whether performed visually or with machine learning algorithms - and therefore subject to errors. We set out to elucidate the nature of these errors in more than 5,000 motor units decomposed from surface EMG signals collected during human voluntary contractions. Errors were identified from the decomposition of the EMG signal followed by repeated validations using the previously developed reconstruct-and-test approach. We classified two types of errors. Position errors were defined as variability in the temporal localization of the each motor unit firing. These errors were pseudo-normally distributed around zero. The standard deviation of the error ranged from 4 to 10 ms and was directly proportional to the temporal width of each motor unit action potential. Identification errors were found at longer latencies and consisted of false positives or missed detections of firings. These errors likely occurred from confusions between similarly shaped motor unit action potentials. While computations of mean motor unit firing rate were minimally (< 5%) affected by these errors, the values and distribution of inter-pulse intervals were affected to a greater extent. To mitigate these decomposition errors, we derived an algorithm to improve the estimate the firings of each motor unit. The original decomposition and validation results of each motor unit firing train were defined as independently obtained estimates or samples of the true motor unit firing times: containing a physiological deterministic component plus some error. Position errors were corrected by averaging the temporal locations of matched firings across estimates of the same motor unit. Identification errors were mitigated by retaining or discarding firings based on a decision criterion for the proportion of unmatched events to total number of estimates at each firing instance. This algorithm produces a new train representing the purest possible estimate of the true physiologic firings for each motor unit. Our algorithm works for any number of estimates of each motor unit firing train. Furthermore it is not limited to any specific decomposition strategy. Rather, this error mitigation technique can be implemented with a multitude of decomposition techniques ranging from visual template matching to machine learning algorithms.

Title: Task specific relation between recruitment and firing rate of motor unit examined via the surface electromyogram

Authors: X. HU[1], H. SHIN[2], A. SURESH[1], *W. Z. RYMER[1,2], N. SURESH[1]
[1]Rehab Inst. Chicago, CHICAGO, IL; [2]Northwestern Univ., Evanston, IL

Abstract: Voluntary muscle force control is accomplished by a combination of recruitment of motor units (MUs) and firing rate modulation of active MUs. There have been contradictory observations regarding the relation between peak firing rate and recruitment threshold of MUs. Namely, studies have shown that the earlier recruited MUs tend to reach lower peak firing rates than the later recruited MUs, that is there is positive correlation between peak firing rates and recruitment thresholds; whereas other studies have found inverse relation between peak firing rates and recruitment thresholds, termed ‘onion-skin principle’. In the current study, we hypothesize that the ‘onion-skin’ was specific to individual force contraction levels, and that the later recruited MUs have yet received excitatory drive that is high enough for these MUs to reach their peak firing rates within a specific contraction level. As a result, the lower plateaued firing rates observed in the high threshold MUs was an effect of plateaued excitatory drive.
Subjects performed an isometric ramp up-hold-relax abduction task of different contraction levels (ranged from 20% to 50% of the maximum voluntary contraction (MVC)) using their index finger. Surface electromyogram (EMG) of the first dorsal interosseous was recorded using a novel surface senor array. We obtained the firing activities of single MUs using a recently developed surface EMG decomposition technique. The peak firing rates were estimated from the initial plateau point of firing rates over time during ramp force. The plateaued firing rates of MUs occurred after the ramp force were also calculated.
Consistent with our prediction, our preliminary results show that 7.4, 63.1, 59.6, and 87.4 % of the analyzed MUs reached peak firing rate during force ramp at 20 to 50% MVC contractions, respectively. The MUs with similar MUAP sizes that showed plateaued firing rates after the ramp force at low contraction levels (low excitatory drives) showed higher peak firing rates

during the ramp force at high contraction levels (high excitatory drives). Additionally, the peak firing rates of MUs with common recruitment threshold across force levels showed no obvious association with the recruitment force, suggesting an absent or weak 'onion skin' across tasks.

Title: Effects of visuomotor integration on motor unit coordination

Authors: *C. M. LAINE, F. NEGRO, D. FARINA
Neurorehabilitation engineering, Univ. Goettingen, Goettingen, Germany

Abstract: Muscle contractions require integration of command signals with afferent feedback in order to appropriately control force, time course, and precision. In laboratory settings, muscle contractions are often investigated in isometric conditions and subjects are given visual feedback of the muscle force output or of the level of EMG activity. The type of feedback may, however, alter the neural drive to the muscles. In this study, we address the influence of visuomotor integration on the behavior of motor units during voluntary muscle contractions. Subjects performed isometric contractions of the first dorsal interosseous (FDI) muscle while slowly and randomly varying the force level in the interval between 6 and 10 % MVC (this interval was shown through visual feedback of force) (no-target condition). To assess the impact of visuomotor integration, subjects repeated the same force fluctuations using a visual display of their previously generated force as a target (target-tracking condition). Task-related effects on motor unit coordination were assessed using coherence analysis. A total of 38 motor unit pairs were recorded from 2 subjects under both experimental conditions. No statistical differences were found between firing rates (mean(SD)=11.85(2.05) Hz vs. 11.69(1.38) Hz) or firing rate variability (CV of ISIs= 0.25(.05) vs. 0 .25(.05)) for no-target and target-tracking conditions, respectively. However, the coherence between motor unit pairs was significantly greater in the 5-10 Hz frequency band in the no-target than in the target-tracking condition, while high frequency coherence (15-40 Hz) was significantly increased in the target-tracking task. These data suggest

a frequency-specific modulation of common synaptic drive to motor neurons when visual input is used to guide force production.

Title: Motor unit activity patterns in awake mice

Authors: *V. M. TYSSELING[1], L. RITTER[2], C. J. HECKMAN[1], M. C. TRESCH[2]
[1]Dept. of Physiol., Northwestern Univ., CHICAGO, IL; [2]Biomed. Engin., Northwestern Univ., Chicago, IL

Abstract: Recent work in anesthetized animals has suggested that modulation of muscle force in mice is primarily accomplished by varying the recruitment of motor units rather than varying the firing rate of already recruited units. Such recruitment based force modulation would be in contrast to findings in other animals that appear to use both recruitment and rate modulation. Further, individual motor units were often recruited at a very high rate in response to a slow depolarization. However, in the absence of motor unit recordings in behaving mice, it is unclear whether a similar recruitment based mechanism of force modulation takes place during natural behaviors. In this study, we successfully recorded motor units with good isolation via percutaneous electrodes in the lateral gastrocnemius of awake, quiescent mice. Sterilized 20 micron diameter stainless steel wires in a duplex configuration were used for the recording of single motor units. Gross EMGs were recorded simultaneously using 50 micron diameter stainless steel wires, also in a duplex configuration, with the recording surfaces separated by 2mm to record from a population of motor units. Candidate single motor units (SMUs) were detected by voltage threshold crossing then isolated using custom software written in Matlab to perform spike sorting and examination of individual waveforms. The quality of unit isolation was evaluated by examining distributions of interspike intervals and quantifying the L-ratio of

clusters (L-ratio < .05; Schmitzer-Torbert et al., 2005). Periods of steady firing ranging from 3 seconds to 14 minutes duration were included in subsequent analyses. We observed a wide distribution of firing rates across single motor units, including both low and high firing rates: modes for single unit frequency distributions ranged between 10-60Hz. Analysis of the relationship between these firing rate variations and the simultaneously recorded gross EMG will allow us to further examine the recruitment vs. firing rate modulation in the mouse. These recordings provide critical information about motor unit activations that can be compared to previous findings in reduced preparations, helping understand the contributions of synaptic inputs and intrinsic properties to MN activity during natural behavior.

Title: The control of motor units does not maximize force production

Authors: *P. CONTESSA[1,2], E. C. HOSTAGE[1], C. J. DE LUCA[1]
[1]Boston Univ., Boston, MA; [2]Univ. of Padova, Padova, Italy

Abstract: Early studies of the firing behavior of electrically stimulated animal motoneurons by Eccles (1958) and Kernell (1965, 2003) have generated the widely accepted hypothesis of a direct relationship between motoneuron firing rate and after-hyperpolarization. It has been posited that the after-hyperpolarization determines motoneuron firing rate, leading to greater firing rates in phasic (higher-threshold, larger-diameter) motoneurons and lower firing rates in tonic (lower-threshold, smaller-diameter) motoneurons. In this control scheme, the firing rate is matched to motor unit force twitch duration to provide fused tetani and maximizing force production.
We investigated motor unit firing behavior during voluntary isometric contractions in humans.

Surface electromyographic signals were recorded during the contractions and decomposed into the constituent motor unit action potential trains using the algorithm recently developed by De Luca et al. (2006) and Nawab et al. (2010). The mean firing rates of motor units was calculated from the firing trains and analyzed as a function of time and muscle force.
We found that firing rates increased as negative exponential functions with increasing muscle force; and that the time constant of the exponential functions was directly related to motor unit recruitment threshold. At any time and force level, including at recruitment, the firing rate values were inversely related to the recruitment threshold of the motor unit. Consequently, later-recruited motor units showed progressively lower firing rates than earlier-recruited motor units. This behavior was mathematically modeled in a set of equations named the "firing rate spectrum".
We believe that the disparate reports between our results on human subjects and the early studies on animal motoneurons stem from a different behavior of motoneurons when electrically vs. voluntarily activated. Larger-diameter later-recruited motoneurons may have the capacity of firing at greater rates than smaller-diameter earlier-recruited motor units, but they do not do so during voluntary isometric contractions. Instead, the higher-threshold, higher-amplitude and shorter-duration force-twitch motor units fire at lower rates and do not tetanize. This hierarchical control scheme does not enhance force. Instead, it enhances a combination of force and time duration by providing effective force generation for the earlier-recruited motor units and by reducing the fatigue of later-recruited motor units. The high-threshold motor units generally fatigue faster and could not sustain force if they were to fire at relatively greater rates.

Title: Estimates of neural drive using motor unit action potential analysis

Authors: *N. L. SURESH[1], A. K. SURESH[2], X. HU[2], W. Z. RYMER[2,3]
[1]Sensory Motor Perf Prgm, Rehabil. of Chicago, CHICAGO, IL; [2]Sensory Motor Performance Program, Rehabil. Inst. of Chicago, Chicago, IL; [3]Biomed. Engin., Northwestern Univ., Evanston, IL

Abstract: *Abstract :*
INTRODUCTION Force production during voluntary isometric muscle contraction is generated through a combination of motor unit(MU) recruitment followed by increased firing of active motor units. MU recruitment order is a function of motoneuron size while the expected MU firing rate paradigm is such that the earlier, smaller recruited units fire at a slower rate than the units recruited later during the same force tasks. In this way the MU recruitment and firing rate pattern is optimized for maximal and efficient force production. During trapezoidal isometric force tasks, the reverse firing rate paradigm has routinely been observed. The objective of this study is to characterize and compare MUAP size as well as estimated 'neural drive' across varying levels of (trapezoidal) isometric force tasks. METHODS Surface EMG of the first dorsal interosseous(FDI) muscle was recorded from 3 healthy individuals. The subjects performed sustained isometric abductions at 4 different force levels (20%, 30%, 40%, and 50% of maximum voluntary contraction) each with 2 repetitions. Single MU firing activities were decomposed from the sEMG using the decomposition system (Nawab et al. 2010). A spike triggered average (STA) on the sEMG was performed to estimate the action potential (AP) shapes. The peak-to-peak amplitude of the STA MUAP was calculated as the estimated size of the motoneuron. The mean, median and range of the MUAP amplitudes for each trial and each subject were determined. Amplitude histograms of the MUAP amplitude were constructed using the number of firing times for each MU as the histogram count. The cumulative (discrete) integral of the amplitude histogram was performed. RESULTS All three subjects showed a progressively increasing MUAP amplitude range as a function of force contraction level. The cumulative integral exhibited a ramp increase followed by a plateau for a given trial and exhibited graded levels as function of task force, i.e., across trials. DISCUSSION Preliminary results from our study show that MU size increases across increasing force task levels and that the 'onion skin' firing rate pattern results in a 'neural drive' signal that is proportional to the required force for a trapezoidal force task with graded values as a function of force level.

Title: The influence of the magnetic stimulation on characteristics of the motor system

Authors: *R. M. GORODNICHEV[1], A. BELYAEV[2]
[2]physiology, [1]Velikiye Luki State Acad. of, Velikiye Luki, Russian Federation

Abstract: The purpose of this research was to study the effects of the magnetic stimulation of skeletal muscles on maximum strength (maximal voluntary torque, MVT), amplitude H-reflex and M-wave.
18 subjects aged 19-22 performed 10 sets of concentric muscle contractions (plantar flexion in the dynamographic Biodex Multi-Joint System) daily during 10 days. These contractions made 80% of maximal voluntary contraction. 9 subjects of experimental group received magnetic stimulation with frequency 5 stimulus per second during each muscle contraction. Magnetic stimuli were applied to the gastrocnemius muscle by Magstim 200 magnetic stimulator.
It was revealed that after 10 days of the training MVT increased in subjects of the experimental group from 124.1 ± 8.8 Nm to 188.7 ± 12.2 Nm and amplitudes of the H-reflex m. gastrocnemius increased from 0.73 mV to 0.95 mV. MVT in control group subjects increased much less in comparison with the experimental group and the amplitude of the H-reflex did not change.
The present results suggest that magnetic stimulation of the muscles could change the performance of the motor command.

Title: Modulation of intermuscular coherence by functional electrical stimulation.

Authors: *J. A. NORTON[1], H. ADAMSON[2]
[1]Neurosci., Univ. of Alberta, Edmonton, Canada; [2]Neurosci., Univ. of Alberta, Edmonton, AB, Canada

Abstract: Intermuscular coherence is known to be dependent upon feedback from the somatosensory system. Coherence between muscles has been proposed as a control source for Functional Electrical Stimulation. The purpose of this study was to examine what the effect of electrical stimulation on intermuscular coherence.
Fifteen neurologically intact subjects were recruited. Electromyographic activity was recorded from forearm extensors and finger extensors from the dominant hand. Electrical stimulation was applied to the same forearm extensors as were being recorded. Stimulation was applied at 20Hz at intensities that were ½ sensory threshold, sensory threshold, 2 times sensory threshold, motor threshold and 2 times motor threshold. During EMG recordings subjects maintained an isometric contraction. The order of stimulation was randomized.
EMG data was full wave rectified and coherence calculated between the two muscles using Neurospec software in Matlab. The peak frequency at which coherence was seen (above the 95% confidence limit and with appropriate phase, and lasting for at least 3 frequency bins contiguously) was recorded. We compared both individual and grouped responses using chi-squared measures of difference.
At low stimulus intensities (1/2 and 1 times sensory threshold) the stimulation there was no effect on the coherence in terms of either the peak frequency (excluding the stimulus artefact) or areas of coherence. At frequencies of 2 times sensory threshold or higher the peak frequency of coherence shifted away from the frequency of stimulation.
The lack of effect on intermuscular coherence of stimulation below two times sensory threshold, with a consistent effect above that level of stimulation suggests that Ia and/or Ib fibres may be responsible for providing at least a part of the sensory feedback portion of intermuscular coherence.
Further work is needed to elucidate more clearly these mechanisms.

Title: Dual coupling of β_2-adrenoceptors to G_s and G_i proteins in skeletal muscle involves extracellular cyclic AMP - adenosine pathway

Authors: *T. DUARTE[1], R. O. GODINHO[2]
[1]Farmacologia, [2]Pharmacol., Univ. Federal De São Paulo, São Paulo, Brazil

Abstract: The primary action of β_2-adrenoceptor (β_2-AR) agonists depends on activation of stimulatory G (Gs) protein and increased generation of cyclic AMP. However, in many tissues, β_2-AR-mediated responses are affected by promiscuous coupling of these receptors to other Gα subunits, especially the inhibitory Gαi subfamily. In skeletal muscle, activation of β_2-AR have been associated to cAMP-dependent potentiation of contraction force and reduced proteolysis. In the present study we investigate the possible dual coupling of β_2-AR to Gs and Gi proteins at skeletal muscle and the influence of the β_2-AR/Gs-Gi/cAMP signaling cascade on muscle contraction. Assuming that the increment of intracellular cAMP is followed by cAMP efflux and extracellular generation of adenosine, the contribution of the extracellular cAMP-adenosine pathway on the β_2-AR inotropic response was also addressed. The effects of clenbuterol (10-1000 nM; β_2-AR agonist), forskolin (1 μM; adenylyl cyclase activator) and cAMP was evaluated on the isometric contractility of adult mouse diaphragm muscle induced by transmural electrical stimulation (0.1 Hz, 2 ms duration). Clenbuterol and forskolin induced transient positive inotropic effects. The maximum clenbuterol effect, observed 30 min after stimulation onset, was followed by a negative inotropic effect, which was mimicked by either cAMP (10 μM) or adenosine (10 μM) and abolished by pre-incubation of diaphragm with pertussis toxin (PTX; Gi signaling inhibitor) or the organic anion transporter inhibitor probenecid. Remarkably, the PTX-sensitive β_2-AR inotropic effect was inhibited by the A_1 adenosine receptor antagonist DPCPX (50 μM) , indicating that β_2-AR coupling to Gi is indirect and dependent on A_1 adenosine receptor activation. The involvement of extracellular cAMP-adenosine pathway in the regulation of the β_2-AR inotropic response herein presented provides a negative feedback loop, which may limit Gs protein-coupled receptor response and possible harmful exacerbation of muscle contraction.

Title: Coherence between motor unit spike trains in human tibialis anterior muscle is influenced by ankle joint angle

Authors: *F. NEGRO, U. YAVUZ, D. FARINA
Dept. of Neurorehabilitation Engin., Univ. Med. Ctr. Göttingen, Goettingen, Germany

Abstract: During sustained isometric contractions, the motor unit (MU) spike trains show a significant level of correlation [1] that is evident in the frequency domain as coherence peaks in the α-band (6-12 Hz) [2]. These α-band components have been demonstrated to be in phase with force oscillations [2]. The origin of this phenomenon is still not completely understood, but there is evidence [2] that suggest a role of the afferent loop. In this study, we investigate the possibility of modifying the common tremor components in the motor unit spike trains by changing the joint ankle angle and therefore the length of the muscle. Three men (age range 24-30 yrs) performed a 50 s isometric dorsiflexion at 5 and 10 % MVC with different joint ankle angle at 0° (maximal dorsiflexion angle), 20°, 40°, and 60°. Intramuscular EMG signals were recorded with two pairs of bipolar wire electrodes from the Tibialis Anterior (TA) muscle and analyzed with a decomposition algorithm [3]. The coherence function (epochs of 1 s) was calculated between all pairs of motor unit spike trains and averaged. Multiple spike trains were also combined in composite spike trains (CST. The frequency of the highest coherence peak in the α-band (6-15 Hz) was calculated for all contractions. Only motor units that were active from the beginning to the end of the contraction were analyzed. In total, 211 motor units (9 ± 4 per contraction) were used for the computation of the coherence measures. At 5 % MVC, the averaged significant coherence peaks between pairs of motor unit spike trains were 7.8 ± 0.1 Hz for 0° angle and 6.9 ± 0.3 Hz for 20°. At 10 % MVC, the averaged coherence peaks were 8.8 ± 0.4 Hz for 0° angle and 7.9 ± 1.0 Hz for 20°. The magnitude of these coherence peaks was on average 210 ± 53 % of the confidence level. For higher ankle joint angles, the magnitude of the coherence between pairs of motor units was lower compared with the other cases (on average, 110 ± 14 % of the confidence value). Therefore, we calculated the CST to identify better the locations of the peaks for these angles. At 5 % MVC, the averaged significant coherence peaks between pairs of MUs spike trains were 11.2 ± 0.8 Hz for 40° angle and 12.5 ± 0.5 Hz for 60° degrees. The results for the 10 % MVC were similar and not statistically different. In conclusion, our results demonstrated that the length of the muscle influences the tremor frequency components present in motor unit spike trains, which is supportive of the hypothesis that such components are originated by the afferent feedback loop.

Title: Octopamine and tyramine modulate synaptic properties and muscle contractions in *Drosophila*

Authors: K. G. ORMEROD[1], J. K. HADDEN[2], A. SCIBELLI[2], M. MILAKOVIC[1], A. J. MERCIER[1], *J. L. KRANS[2]
[1]Brock Univ., St. Catharines, ON, Canada; [2]Neurosci., WNE, Springfield, MA

Abstract: Octopamine (OA) and tyramine (Tyr) have been described as arthropod fight or flight hormones, although the mechanisms by which these biogenic amines act at the synapse and particularly on larval muscle force production in *D. melanogaster* are poorly understood. The present work utilizes identified muscle fibers in the body wall of 3rd instar *D. melanogaster* larvae to distinguish between OA- and Tyr-modulated changes at synapses and intramuscularly. To elucidate the effects of the biogenic amines on muscle fibers we initially characterized the effects of OA and Tyr on input resistance and basal tonus. OA elicited a dose-dependent decrease in input resistance between 10^{-8} and 10^{-4} M (2±2 and 17±8%, respectively). Tyr did not induce any changes in input resistance at 10^{-8} - 10^{-4} M. OA also induced a dose-dependent increase in basal tonus at 10^{-10} - 10^{-4} M (0.13±0.13 - 1.86±0.18 mN or 293±62 - 980±163% of resting tonus, respectively), while Tyr did not induce any significant changes in basal tonus. We next sought to characterize the roles of OA at the synapse by recording compound excitatory junctional potentials (EJPs) and larval body-wall muscle force production by synaptic and direct stimulation. OA (10^{-8} and 10^{-4} M) induced a dose-dependent increase in EJP amplitude (8±3.2 - 34±2.9%, respectively) and increased synaptically driven force production in a notably parallel manner between 10^{-8} and 10^{-4} M (125.7±23.2 - 496±30.3 uN or 13±4.6 to 32.6±6.1% of peak force, respectively). OA also significantly increased the decay constant of muscle relaxation (208±27 ms; 46.9±13.1% at 10^{-4}) compared to saline control trials. To further characterize the effects of OA on muscle fibers specifically, we activated muscle fibers directly to minimize or

eliminate contributions of the synapse. Results from direct stimulation of muscle parallel those of synaptic activation. The OA-induced changes in basal tonus far exceed those of evoked contractions and suggest involvement of a long-term change to an as yet unidentified intramuscular protein. We suspect that giant sarcomere associated proteins (gSAPs) are a major player in muscle plasticity. We are using UAS-RNAi to knock-down expression and investigate the role these proteins play in OA-mediated changes in EJPs, muscle input resistance, basal tonus, synaptically driven and directly stimulated muscle contractions. Our results indicate that there is little postsynaptic and muscle-specific action of tyramine. The action of octopamine, on the other hand, is profound and provides a useful experimental treatment for investigating muscle plasticity.
JKH and KGO contributed equally to this project.

Title: Genioglossus motor unit activities in quasi speech tasks

Authors: S. TAKANO[1], A. LACROSS[1], P. J. WATSON[2], *F. BAILEY[1]
[1]Physiol., The Univ. of Arizona, Tucson, AZ; [2]Speech, Language and Hearing Sci., Univ. of Minnesota, University of Minnesota, MN

Abstract: Previous studies have characterized the single motor unit (SMU) activities of the genioglossus (GG) muscle in human subjects. This previous work has as its focus the respiratory-related activities of the GG and its role in preserving airway patency. In contrast, scant attention has been given to volitional movement of the tongue and the role that the GG plays in creating constrictions that modify the expired airstream for purposes of speech production. Here we used tungsten microelectrodes inserted into the GG muscle of healthy adults (3 men, 2 women; ages 22-25 years) to record SMU activities at rest and during articulation of the isolated open back and front vowels /a/ and /ae/, respectively. We simultaneously recorded motions of the rib cage and abdomen, the acoustic signal and single motor unit activities in the

following conditions: phonation, whisper, and electro-larynx to assess the separate and combined effects of respiratory, phonatory (laryngeal) and supra-laryngeal (oral-articulatory) subsystems, on MU activities. The range of GG MU firing rates recorded in these quasi speech tasks (range 9.1 - 22.4 Hz) is typically lower than for either rest breathing (range 19.8 - 22.5 Hz) but approximates firing rates previously reported during tongue protrusion (13.1 - 16.1 Hz) (Bailey et al 2007). Firing rate variability appears greater in quasi speech tasks than in either rest breathing or non-speech volitional protrusion. Minimum and maximum MU firing rates and firing rate variability are significantly greater for front versus back vowels. Such variability may reflect differences in the magnitude of displacement of the tongue from the rest condition. Moreover, greater variability in MU firing rates in speech production as compared to rest breathing or simple tongue protrusion are consistent with variations evident within phonemic categories (Liberman et al. 1957; Moore et al. 1988). These preliminary findings offer de novo insights into tongue muscle and motor unit activities as a function of the successive superimposition of respiratory, phonatory and articulatory subsystems.

Title: Sensory evoked excitation of antagonistic motor groups

Authors: P. M. SONNER, *D. R. LADLE
Neurosci, Cell Bio, Physiol, Wright State Univ., DAYTON, OH

Abstract: Integration of sensory feedback with centrally generated motor commands is critical for adaptation of movement following perturbations from the environment. Sensory information influences motor neuron (MN) output directly via monosynaptic connections from Ia afferents and indirectly through various interneuron pathways in the spinal cord. A well characterized sensory-motor relationship is inhibition of flexor MNs of the knee joint (posterior biceps and semitendonous [PBST]) by activation of knee extensor Ia sensory afferents (Quadriceps [Quad]).

This phenomenon, known as reciprocal inhibition, is largely mediated by glycinergic Ia inhibitory interneurons (IaINs). We have characterized the efficacy of reciprocal inhibition during early postnatal development (P1-P7) in mice, when the animal begins to interact with the external environment. Interestingly, we have also found evidence for an excitatory interneuronal pathway between Quad afferents and PBST MNs at these early stages.
Inhibition of PBST MNs via Quad afferents was measured at P1 and P7 using a hemisected, isolated spinal cord preparation from wild-type mice. PBST MN excitability was measured indirectly by quantifying the area of the extracellular compound action potential (CAP) recorded from the PBST nerve via a suction electrode in the periphery evoked by stimulation of the L5 dorsal root (DRL5) at 0.1Hz. These “test” stimuli were alternated with “conditioning” stimuli in which the Quad nerve was stimulated at various intervals (0-50ms in 2ms increments) prior to stimulation of DRL5.
In all P1 and P7 preparations, conditioning with Quad stimulation resulted in reduction of the DRL5 to PBST test pulse CAP. As classically described for reciprocal inhibition, the greatest inhibition was observed at conditioning pulse intervals consistent with a disynaptic linkage between Quad afferents and PBST MNs. This inhibition was blocked by addition of 0.4μM strychnine. In the presence of strychnine, however, stimulation of Quad afferents evoked a CAP in PBST MNs, even in the absence of DRL5 stimulation. This was observed in 6/6 P7 preparations, but never observed in the absence of strychnine. Unlike the disynaptic reciprocal inhibition pathway, we found the latency of the Quad-PBST excitatory pathway was consistent with a trisynaptic linkage between Quad afferents and PBST MNs. Experiments in P1 mice suggest this excitatory pathway is also functional at the time of birth. Ongoing experiments aim to determine if normal levels of glycinergic inhibition act to suppress interneurons mediating this excitatory response on PBST MNs and whether this excitatory circuit persists during mature locomotion.

Title: Passive length changes of human muscle with respect to tendon indentation and joint rotation - An ultrasound study

Authors: *M. K. CHARDON, W. Z. RYMER
SMPP, Rehabil. Inst. of Chicago, Chicago, IL

Abstract: In human muscle, most of the passive length changes have been measured with respect to joint rotation. On the other hand, passive length changes measurements relative to tendon indentation are still relatively unknown. In fact, background search has failed to provide any previous work. In this study we sought to quantify passive length changes of the biceps brachii with respect to its distal tendon indentation. We describe the use of a novel tendon indentation device used to indent the tendon, an arm rotation device used to rotate the lower arm around the elbow and the use of sagittal ultrasound images of the biceps brachii to measure length changes. Our preliminary result shows that a 20 mm indentation is equivalent to a 15 degree arm rotation. We expect that the result will confirm that tendon indentations are physiologically equivalent to a range of joint rotation and thus can be used as an input to muscle stimulation protocols.

Title: Reverse frequency adaptation and discharge properties of rat hindlimb motoneurons in the subprimary range

Authors: V. V. TURKIN[1], D. O'NEILL[2], *T. M. HAMM[3]
[1]Divison of Neurobio., [2]Div. of Neurobio., Barrow Neurolog. Inst., Phoenix, AZ; [3]Div. Neurobio., Barrow Neurolog. Inst., PHOENIX, AZ

Abstract: The frequency-current (fI) relation of rat hindlimb motoneurons has an initial high-gain subprimary range that likely exerts a substantial influence on rate modulation on force development (Turkin et al., 2010). We compared responses of rat hindlimb motoneurons to 10-second injected current steps and ramps to determine the dependence of discharge characteristics on excitation profile and characterize the responses to sustained levels of excitation within the subprimary range. Comparisons were made in 8 antidromically identified motoneurons. Six of the 8 motoneurons exhibited an initial reverse frequency adaptation at smaller injected current

steps and discharge rates. In these cases the rate of discharge increased during the first 1-2 seconds before reaching a plateau or adapting. Discharge during reverse adaptation was variable and associated with interspike intervals that often exceeded the duration of the hyperpolarizing trajectory of membrane potential following each action potential. Reverse adaptation was observed at discharge frequencies less than the transition frequency between the subprimary and primary ranges in ramp-generated fI plots. Typical adapting responses were observed at larger currents and frequencies. Frequency-current plots derived from step responses had subprimary ranges in some cases, but the narrow current window of the subprimary range combined with irregular discharge during reverse adaptation and adaptation sometimes prevented conclusive determinations. Discharge variability, assessed as the standard deviation of the interspike interval (ISI) increased with mean ISI. This relation included an inflection as observed in human motor unit and cat motoneuron discharge. This inflection occurred at ISIs which were considerably shorter than the afterhyperpolarization (AHP) produced by an injected current pulse at resting membrane potential, but which approximately matched the duration of the hyperpolarizing membrane potential trajectory during discharge. These trajectories were substantially shorter than the AHP at resting membrane potential. These results suggest that time- and activity-dependent changes in motoneuron intrinsic properties and excitability following the onset of activity contribute to the subprimary range and the near-threshold discharge characteristics of rat motoneurons.

Title: Expression of myogenic markers in a pelvic and a perineal striated muscle of nulliparas and multiparas rabbits

Authors: K. LÓPEZ-GARCÍA[1], I. JIMÉNEZ[2], E. CUEVAS[3], *F. CASTELÁN[3], P. PACHECO[4], M. MARTÍNEZ-GÓMEZ[4]

[1]Doctorado en Neuroetología, Univ. Veracruzana, Xalapa, Mexico; [2]Fisiología, Biofísica y Neurociencias, Cinvestav, México, DF., Mexico; [3]Ctr. Tlaxcala de Biología de la Conducta, Univ. Autónoma De Tlaxcala, Tlaxcala, Mexico; [4]Inst. de Investigaciones Biomédicas, Univ. Nacional Autónoma de México, México-DF., Mexico

Abstract: Pelvic and perineal skeletal muscles are critical for the physiology of the lower urogenital tract in human and other mammal species. Vaginal delivery causes structural and functional changes in both muscles that in women are related with the onset of pelvic organ prolapses and urinary dysfunctions. By using female rabbits we have previously found that multiparity affects the EMG activity during micturition and contractility properties of the pubococcygeus (Pcm; a pelvic muscle) and the bulbospongiosus muscles (Bsm; a perineal muscle). Those effects coincide with histological alterations suggesting a process of skeletal muscle regeneration, which is mediated by activation and differentiation of satellite cells. At our present work, myogenic markers expressed in diferent stages of skeletal muscle regeneration (Pax7, MyoD, MyoG and desmin) were measured by immunohistochemistry in the Pcm and the Bsm of nulliparous and multiparous (4 consecutive deliveries) age-matched rabbits. Additionally, the activity of muscle β-glucuronidase was measured as a parameter of muscle damage. Results showed a similar expression of Pax7 in the Pcm and the Bsm of nulliparas and multiparas. At postpartum days 3 and 20, the expression of MyoD and MyoG remains unchanged in the Pcm whereas a higher expression of both was found in the Bsm only at pospartum day 20. The expression of desmin was increased in the Bsm of multiparas from postpartum day 3 to 20, whereas in the Bsm only was high at postpartum day 20. A high activity of β-glucuronidase from total protein extracts of the Pcm was measured at postpartum day 20. For the Bsm, the activity of β-glucuronidase was high at postpartum day 3, returning to the basal one at postpartum day 20. Collectively, our results suggest that the particular expression of myogenic markers in the Pcm and the Bsm might be related with the extent of damage for each. The later may depend on fiber composition, contraction exerted because of pregnancy and delivery, and hormonal factors related to reproductive experience.

Title: Consequences of the wide spread distribution of HCN channels on the intrinsic resonance properties of the dendritic tree of neck motoneurons

Authors: *P. ROSE[1], K. FENRICH[2], R. MARATTA[1], M. NEUBER-HESS[1], E. ZHAO[1]
[1]Queens Univ., Kingston, ON, Canada; [2]Inst. de Biologie du Développement de Marseille-Luminy (IBDML), Marseille, France

Abstract: Hyperpolarization-activated cation (HCN) channels act as resonating conductances. In motoneurons this feature leads to a subthreshold resonance with a frequency of 6 to 20 Hz at the soma. As a consequence, the input-output properties of motoneurons depend, in part, on the frequency of oscillations in synaptic activity. The goal of the present study was to extend the description of motoneuron intrinsic resonance properties to include the dendritic tree.
As a first step to meet this goal, we used a combination of immunocytochemical and image analysis techniques to quantitatively describe the distribution of one of the subunits that form HCN channels, HCN1, on the somatic and dendritic membranes of intracellularly stained neck motoneurons in the adult cat. HCN1 subunits were labeled with a specific antibody (NeuroMab clone N70/28). Analysis of HCN1 labelling was constrained to juxta-membrane regions. For each motoneuron, 30 to 90 dendritic segments located 100 to 1800 μm from the soma were examined.
For 7 of the 10 motoneurons examined, membrane-associated density of HCN1 was greater on distal, compared to proximal, dendritic segments. The increase was a linear function of distance such that density increased 40 to 110% every 1000 μm. For the other 3 cells, the slope was statistically not different from zero. There was a negative correlation between the slope and the HCN1 density of the most proximal dendrites such that HCN1 density was similar in 9 of 10 motoneurons, 800 to 1200 μm from the soma.
To determine the functional consequences of the distribution patterns of HCN1 on the intrinsic resonance properties at different regions of the dendritic tree, we constructed compartmental models of motoneurons with uniform and non-uniform distributions of HCN channels that matched the experimentally observed distribution of HCN1 subunits. Despite the differences in HCN channel distribution, both models had similar intrinsic resonance properties. The subthreshold resonance increased from approximately 6 Hz on proximal dendrites to 11 Hz at the distal dendrites. Thus, different regions of the dendritic tree are tuned to different frequencies of input oscillations. This increase in computational power was associated with a large decrease in the efficacy of current transmission to the soma for input oscillations with frequencies of less than 0.5 Hz. These signals were five times weaker than the same signals on models with no HCN channels. Thus, HCN channels on motoneuron dendrites may amplify local responses to synaptic activity in a location and frequency dependent fashion and filter the transmission of synaptic currents generated by slow oscillations in synaptic activity.

Title: Visuomotor correction in older adults increases the variability in muscle force and motor unit discharge in tibialis anterior

Authors: *A. M. GROSSMAN, M. FRITZ, A. AMIN, M. TRABERT, A. JONES, R. PAXTON, B. TRACY
Hlth. and Exercise Sci., Colorado State Univ., Fort Collins, CO

Abstract: Force variability and motor unit discharge variability is often greater for older adults. This effect has been shown for small hand muscles and proximal leg muscles, and is more robust and consistent at low forces and high visual feedback gain. It has been suggested this is due to impaired visuomotor processing by older adults. However, the effects of visuomotor processing on the variability of force and motor neuron discharge have not been well characterized in the ankle muscles of older adults. The purpose was to determine the effect of high gain visual feedback on the variability of force and motor unit (MU) discharge in the dorsiflexor (DF) muscles of older adults. Older adults (79 ± 7yrs, 67-94yrs, n=37) performed force steadiness trials with the DF muscles while trains of single MU action potentials (AP) were measured via fine wire electrodes inserted into the proximal 1/3 of the tibialis anterior muscle. Trials were performed with (VIS) and without (NVIS) visual feedback of the force. MUAP's were discriminated via computerized algorithm (Spike 2); each discharge was manually confirmed. Recruitment thresholds (RT) were measured during slow ramp contractions. The steadiness trials were performed at a target force just above the RT of the motor unit. The discharge behavior of 59 single MU's (1-2 per subject) were recorded for VIS and NVIS conditions. The mean, SD, and CV of the interspike intervals (ISI) were calculated for 7-20s (13.2 ± 2.6s) of data per trial (119 ± 29 MU discharges per trial). The mean, SD, and CV of force was calculated from the same force epochs. RT's ranged from 0.2-5.5% MVC; 60% of the MU's had an RT under 3% MVC. Mean forces during the steadiness task were low (4.1 ± 2% MVC), therefore the visual gain of the force feedback was high. The CV of ISI was correlated with CV of force for VIS

(r=0.5, P<0.0001) and NVIS (r=0.28, P=0.03). The mean ISI was correlated with the SD of ISI (r=0.66, P<0.0001) for NVIS, such that the variability of discharge increased with slower discharge rates. For NVIS, the mean force exerted was correlated with the SD of force (r=0.4, P<0.01), indicating signal-dependent noise. The CV of force declined with target force (r=-0.28,P=0.03). The mean force and the SD of force were similar between VIS and NVIS. The CV of force was greater for VIS than NVIS (3.9 ± 3.6% vs. 3.1 ± 2.8%, P<0.01). The CV of ISI was also greater for VIS than NVIS (14.5 ± 4.1% vs. 13.4 ± 4.0%, P=0.02). The results indicate that the variability of motor unit discharge contributes to the variability of force, and that older adults exhibit greater variability in the descending command to dorsiflexor motor units when visuomotor processing is an important contributor to the control task.

Title: Extracting motor modules as a measure of interlimb coordination

Authors: S. GERVASIO[1], L. GIZZI[2], *N. MRACHACZ-KERSTING[1], D. FARINA[2]
[1]SMI, Sensory-Motor Interaction, Aalborg Univ., Aalborg, Denmark; [2]Dept. of Neurorehabilitation Engin., Georg-August Univ., Göttingen, Germany

Abstract: The muscular activation symmetry between lower limbs during tasks such as walking can be severely impaired following lesions of the Central Nervous System (CNS), resulting in a limping gait pattern and reduced stability. While it is well know that, even if the injury is located within one cerebral hemisphere, both sides are affected, less is known about the possible role of spinal circuitry connecting the muscles of the lower limbs. A spinal pathway connecting muscles of the lower legs have recently been described (Stubbs & Mrachacz-Kersting, J Neurophysiol: 102, 2009); this pathway is significantly affected in stroke patients and may contribute to gait asymmetry .
While it is widely suggested that the CNS may reduce the complexity related to the execution of

movement and the large number of degrees of freedom by activation of a few motor modules, there is still the need of deepening our understanding of how the CNS controls lower interlimb coordination during walking. This may possibly lead to important implications for locomotor rehabilitation in patient populations.
The existence of central pattern generator (CPG) controlling each leg is a common interpretation; nevertheless, the presence of ipsilateral muscular activity through the whole gait cycle would suggest a complex bilateral control of motorneurons weighted according to the biomechanical demand.
The aim of the current study is to develop a method to investigate interlimb coordination during walking and assess the independence of motor modules of the two legs during such a task. The protocol requires subjects to perform three different walking tasks. The first is normal walking, where motor modules seem to be phase shifted for each leg. During the other two tasks the natural coupling between the two legs is disturbed slightly, by altering the speed of one belt of the treadmill (split-belt walking condition) or considerably, by changing the direction of one treadmill's belt (hybrid walking condition). Muscle activity of trunk and limbs is recorded bilaterally from 16 pairs of muscles (32 muscles in total). Motor modules extracted unilaterally are compared with motor modules extracted bilaterally and during the different walking tasks. Preliminary data showed a higher independence of motor modules of each leg during hybrid compared to normal walking. With this protocol, we are currently investigating lower interlimb coordination in a group of healthy subjects.

Title: To rectify or not to rectify··· An inquisition into the purpose behind rectifying electromyographic data

Authors: *C. DAKIN[1], B. L. LUU[2], J.-S. BLOUIN[2]
[1]UBC, Vancouver, BC, Canada; [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Over the past 25 years much research has gone into understanding the functional coupling between modulation in the sensory-motor pathways and muscle motor unit firing

behavior. In many of these studies oscillatory brain activity, captured using electroencephalography or magnetoencephalography, is correlated using measures such as coherence or cross-correlation with ongoing muscle activity (electromyography). Typically, electromyographic (EMG) signals are full wave rectified prior to their correlation with other signals and the reasoning for this preprocessing step has remained unclear (Boonstra 2010). Recently, researchers have questioned this practice which has elevated the subject of EMG rectification to a topic of much debate. Proponents for rectifying have suggested it accentuates EMG spike timing (Halliday et al. 2010;Yao et al. 2007) and envelope information whereas opponents have rallied against its non-linear distortion of data, suggesting it is an unnecessary and potentially inappropriate step in data pre-processing (McClelland et al. 2012; Neto at al. 2010).

Here we enter into this debate by examining the effects of rectification or applying the Hilbert transform (Myers et al. 2003), another method of signal envelope extraction, on the identification of vestibulo - muscle coupling. Electrical vestibular stimulation provides the ability to add a known input signal to the vestibular system which induces well-characterized changes in muscle firing behavior.

Methods: We re-analyzed data from previous studies in which twenty sinusoidal stimuli (1 to 20 Hz) or a single bandwidth stochastic vestibular stimulus (0-20 or 0-25 Hz) was provided and surface EMG recorded from muscles of the lower limbs. We compared several EMG pre-processing methods (rectification, no rectification and Hilbert transform) to determine which best identifies co-modulation between the stimulus and muscle activity.

Results: We found at low frequencies (< 20 Hz) EMG co-modulation with the stimulus is visually apparent but is not present in the coherence between the stimulus and the un-rectified EMG however it is evident in both the rectified and Hilbert transformed EMG.

Conclusion: While the Hilbert transform may avoid creating the discontinuities associated with rectification of EMG signals, in practice we observed similar SVS-EMG coupling between 0-25Hz for these two methods. We conclude that envelope extraction of EMG data prior to coherence analysis is a necessary step in the detection of coupling between vestibular stimuli and ongoing muscle activity.

Title: Characteristics of sensory interactions in pubococcygeus muscle motorneurons of receptive and non-receptive female rats

Authors: *M. A. LARA GARCIA[1], O. LARA-GARCIA[1], E. CUEVAS[2], A. TOVAR[1], P. PACHECO[1,3]
[1]Inst. de Neuroetologia, Univ. Veracruzana, Xalapa, Mexico; [2]Ctr. Tlaxcala Biología de la Conducta, Univ. Autonoma de Tlaxcala, Tlaxcala, Tlaxcala, Mexico; [3]Inst. de Investigaciones Biomedicas, Univ. Nacional Autonoma de Mexico, Mexico, D.F., Mexico

Abstract: A dramatic transitory female behavioral change during sexual activity is represented by the receptivity period observed in rodents. In late proestrous this phenomenon derives from hormonal effects on neuronal circuits; however, this assumption still has not complete evidence. Here, hopping to provide a direct evidence of a neural mechanism involved during sexual behavioral changes we analyzed in pubococcygeus muscle (Pcm) motorneurons of diestrous and proestrous rats, the plastic properties of its neural circuitry. **Method:** In deep i.p. urethane anesthetized rats, the left Pcm was exposed and two stainless steel electrodes (0.1mm diameter) were inserted at the middle of muscle (3-5mm tip separation). Bipolar recordings, mechanical stimulation (pressure, taping, brushing and traction) of the perineal skin (including clitoral sheath) or/and cervix stimulation with a glass probe were performed. **Result**s: In comparison with diestrous, late proestrous rats showed a reflex activity of Pcm fibers characterized by biphasic potentials of high frequency (20Hz approximately), and uniform amplitude. This reflex activity was easily obtained by gentle skin mechanical stimulation. Continuous pressure or traction evoked continuous tonic high frequency activity that stops, when the stimuli cease or when the cervix was touch during the traction. An after discharge with a duration related to perineal skin traction duration was usually recorded. Diestrous rats did not present this Pcm reflex activity. **Discussion:** Apparently, our procedure allows recording of two or three single muscular fibers that correspond to its motorneuron activity. The
reflexive activity represents the motorneural sensory activation during the receptive period through a circuitry with one of the following characteristics: a) Appearance of spinal cord transitional interneuronal hyper-reactive on sensory inputs; b) Facilitatory activity of Renshaw cells from Pcm motorneurons; c) establishment of bistable properties on Pcm motorneurons.

Title: Muscle-dependent MU recruitment behaviour of the elbow extensors

Authors: *B. HARWOOD[1], B. H. DALTON[3], G. A. POWER[1], C. L. RICE[1,2]
[1]Schl of Kinesiol, [2]Dept. of Anat. and Cell Biol., The Univ. of Western Ontario, London, ON, Canada; [3]Sch. of Kinesiology, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: The majority of studies investigating the elbow extensors report neuromuscular measures from the lateral head of the triceps brachii. Although many properties of this whole muscle group have been described (i.e. torque distribution among the parts), few have investigated the motor unit (MU) properties of the four contributing muscles and their relationship to force production. Initial studies showed surface-detected electromyography of the long and lateral head of the triceps brachii increased linearly with force, but suggested the anconeus muscle reached an upper limit of recruitment at 30% of maximal isometric elbow extensor force. However, these studies did not investigate beyond 30% of maximal isometric contraction (MVC) force output. The purpose of our study was to determine MU recruitment behavior of the long and lateral heads of the triceps brachii, and the anconeus in relation to ramp isometric force production up to 75%MVC. It was hypothesized that MUs of the anconeus would be activated at lower relative forces compared with the other two synergistic muscles, but that anconeus MU recruitment would continue above 30%MVC. Ten healthy males performed three elbow extensor MVCs to determine the subsequent target forces (25, 50, and 75%MVC) used for the ramp isometric contractions. Subjects then performed three ramp isometric elbow extensions at each target force (rate of 5%MVC per second) with at least 2 minutes rest between efforts. Force was recorded with a custom elbow joint dynamometer and intramuscular electromyography was recorded via pairs of fine wire electrodes inserted into the muscle bellies of the lateral and long heads of the triceps brachii, and the anconeus. Preliminary results indicate ~50% higher average recruitment thresholds in the long head of the triceps brachii compared with the other two muscles, which did not differ from one another. Despite a majority of the anconeus MUs being recruited at low relative forces, anconeus MU recruitment thresholds were observed at forces exceeding 40%MVC. These results show differences in MU recruitment of the muscles contributing to elbow extension and challenge previous results that indicated MU

recruitment in the anconeus was complete at or below 30%MVC.

Title: Effect of vibrotactile stimulation on the response time to handle perturbation

Authors: *P. HUR, Y.-H. WAN, N. J. SEO
Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Background: Falls from ladders are a major cause of disabling injuries among workers. Early detection of fall initiation may increase a person's ability to rapidly grasp a ladder with the hand and arrest the falling body. One of the fall detection medium is cutaneous sensation in the hand skin, sensing changes in contact pressure and alerting a person to respond to the fall initiation or perturbation. The objective of this study was to determine if vibrotactile stimulation applied to the upper extremity can enhance a person's cutaneous sensation and accelerate his/her muscular response to perturbation of the hand grip.
Methods: Eleven healthy young adults (age: 25±5 years) grasped an overhead handle with minimal effort at the beginning of a trial. A sudden upward load (20% of grip strength) was applied to the handle at a random time. Subjects were instructed to stop the handle from moving up as quickly as possible. Vibrotactile stimulation was applied to one of the 4 locations of the upper extremity (middle fingertip, thenar area, volar forearm, and dorsal forearm) using a vibration device that can generate stochastic resonance (C-3 Tactor, Engineering Acoustics, Inc., Casselberry, FL). The stimulation intensity was set at 50% of the sensory threshold. The muscle reaction times to handle perturbation were quantified as the time intervals between perturbation and increase in RMS EMG for 8 muscles (Flexor Digitorum Superficialis, Flexor Carpi Ulnaris, Extensor Digitorum Communis, Biceps Brachii, Triceps Brachii, Anterior Deltoid, Pectoralis Major, Latissimus Dorsi). The earliest reaction time among the 8 muscles was used for analysis. Four paired t-tests were used to determine the effect of stimulation on the earliest reaction times for the 4 stimulation locations.
Results: The earliest reaction time to handle perturbation significantly decreased by 9% (p=.008)

with the stimulation applied to the middle fingertip pad (from 93 ± 3 ms to 85 ± 3 ms). The earliest reaction time did not improve when vibrotactile stimulation was applied to other locations ($p>.05$).
Conclusion: Vibrotactile stimulation at the fingertip demonstrated a potential to accelerate people's muscular response to handle perturbation. The present study's finding suggests that the use of vibrotactile stimulation can enhance a person's reaction time to handle perturbation and may help reduce fall injuries from ladders or scaffolds. Future studies may investigate the efficacy of vibrotactile stimulation on motor function of people with reduced sensation such as neuropathy and stroke.

Title: Effects of thumb and index finger fatigue on hierarchical control and synergies in prehension tasks

Authors: *T. SINGH[1], V. M. ZATSIORSKY[2], M. L. LATASH[2]
[1]Dept of Kinesiology, [2]Kinesiology, Pennsylvania State Univ., University Park, PA

Abstract: We investigated the effects of thumb and index finger fatigue on digit forces and points of their application across multiple repetitions of a static prehensile task. The purpose of this study was to explore the ability of the central nervous system (CNS) to reorganize synergies at two levels of a hypothetical control hierarchy involved in multi-digit prehension under fatigue of a digit. At the higher level of the hierarchy, the total force and moment of force produced on an object are distributed between the thumb (TH) and the virtual finger (VF, an imagined finger with mechanical output equal to the involved fingers of the hand), while at the lower level the VF action is distributed among the four fingers. One group performed a one-minute fatiguing exercise with the thumb (*group-thumb*) and the second group performed a fatiguing exercise with the index finger (*group-index*). Following the fatiguing exercise, the subjects repeated the static prehension tasks. Fatiguing exercises caused a significant drop in the normal force

($p<0.05$) and an increase in the vertical tangential force ($p<0.05$) of the exercised digit. The contribution of the normal and tangential forces to the total moment also changed during fatigue in a reciprocal way (*Fatigue*×Group, $p<0.001$) to keep the handle in static equilibrium. For group-thumb, the normal forces generated a larger counterclockwise moment and the tangential forces generated a larger clockwise moment during fatigue. This trend was reversed for group-index. The safety margin of the thumb decreased significantly for *group-thumb* ($p<0.001$). Changes in synergies stabilizing the total grip force were observed at the higher level of control hierarchy (TH-VF) but not at the lower level. The results suggest adaptive adjustments in both mechanical output of the digits and co-variation patterns in multi-digit prehension tasks during fatigue.

Abstract: The superposition principle is a motor control theory in which commands are divided into multiple components, processed separately, and then summated to form complex actions. When applied to grasping, commands are typically broken into grip control - control of forces to prevent object slipping - and moment control - control of forces to maintain object orientation. We have previously examined superposition during an unconstrained static holding task in which moments were exerted outside anatomically-defined axes by changing external mass location. We found the principle to hold true under these conditions, suggesting that it is highly robust. We also found separate control of moments about each anatomical axis (i.e., Mx, My, and Mz), implying a further partitioning of moment control. The objective of the current study was to examine how the separation of control develops over the course of a grasping task, i.e., through

grasp, lift, and hold. We hypothesized that the separation of grip and moment control, and that of the moments about different anatomical axes, would first appear just prior to lift onset.
Ten subjects were asked to grasp, lift, and hold an object vertically under eighteen moment conditions. Force and moment data from all digits were analyzed using principal components analysis (PCA) during several time periods throughout the grasp: specifically, the early and late force rise and lift phases, defined as the periods prior to and during the lift, respectively.
During the early force rise phase, the PCA showed grip force and moment on separate components, however the variables related to Mx, My, and Mz did not appear together on the same principal component, often appearing comingled with one another (e.g., an Mx variable on the same component as an Mz variable). Over the course of the grasp, the complete pattern previously observed during hold phase does evolve: during late force rise phase, sources of moments about the same axis began to coalesce together onto the same components; by early lift phase, all sources of moment for each axis were on the same components, in the same pattern as observed previously in the static hold phase. Taken together, these results suggest that while grip force and moment control remain separately controlled throughout the grasp, the separation of moments about different anatomical axes do not develop until later.
Our findings indicate that separate grip force and moment control are implemented upon contact with the object in a feedforward fashion, whereas separation of moments about individual anatomical axes is developed over the course of the grasp, and may require some feedback control.

Title: Haptic-motor transformations for the control of fingertip distance

Authors: *D. SHIBATA, J. Y. CHOI, J. C. LAITANO, M. SANTELLO
Arizona State Univ., Tempe, AZ

Abstract: Dexterous manipulation relies on the ability to modulate digit forces as a function of digit placement. Although many studies have been devoted to understand the sense of hand or digit position, little is known about the sense of position of the fingertips relative to each other.

We addressed this question using psychophysics to quantify subjects' ability to sense and reproduce the vertical distance between the center of pressure (CoP) of the thumb and index finger pads (d_y) of the right hand ("reference" hand, R_{hand}) using the same or contralateral hand ("test" hand, T_{hand}). The R_{hand} digits were passively placed to three d_ys: thumb CoP 30 mm higher or lower than index finger CoP (d_y = 30 and -30 mm, respectively), and collinear CoP's (d_y = 0 mm). When T_{hand} was the contralateral hand, d_y matching was performed synchronously or with a 10-second delay, both of which required subjects to transfer the sensory information from the R_{hand} to generate d_y with T_{hand}. The matching task involving a delay required subjects to retrieve memory of perceived d_y. We also examined how accurately subjects reproduced d_y by using a different hand posture relative to the R_{hand}. We hypothesized that the matching absolute error (E_{abs}, absolute difference between R_{hand} and T_{hand} d_y) would be (a) greater in the collinear than non-collinear digits position, (b) greater when the posture of the R_{hand} is different than the posture of the T_{hand} hand, and (c) greater when subjects reproduced d_y using the contralateral hand. We also measured the relative error (E_{rel}) by taking into account the directionality of matching errors.

Subjects made larger E_{abs} when matching the collinear d_y (13.9 ± 5.7 mm: mean ± SD) than non-collinear d_y's (d_y = 30 mm: 9.8 ± 2.6 mm, d_y = −30 mm: 10.0 ± 2.3 mm; $P < 0.05$). Larger E_{abs} was produced when the posture of T_{hand} and R_{hand} differed (12.3± 3.4 mm; $P < 0.05$) and when T_{hand} was the contralateral hand (12.2 ± 3.5 mm; $P < 0.05$). E_{abs} was smallest when the task involved the ipsilateral hand with the delay and with congruent hand postures across T_{hand} and R_{hand} (8.7 ± 2.1 mm; $P < 0.05$). With regard to E_{rel}, positive error was produced with delay while negative error was produced with no delay. These findings indicate that the accuracy with which perceived fingertip distance is transferred across hands is lower than when it is reproduced with the same hand. Moreover, the 10-s delay changes the direction of matching error when the task is performed with the contralateral hand. We propose that the erroneous representation of fingertip distance, if not compensated for between contact and onset of manipulation, might lead to performance errors as digit forces have to be modulated to perceived digit placement.

Title: Grip force adaptation to dynamic torques during object manipulation in weightlessness

Authors: *T. GIARD[1], J. MCINTYRE[2], F. CREVECOEUR[3], J.-L. THONNARD[4], P. LEFÈVRE[1]
[1]ICTEAM / IoNS, Univ. catholique De Louvain, Louvain-la-Neuve, Belgium; [2]Ctr. d'Etudes de la Sensorimotricité, CNRS–Université Paris Descartes, Paris, France; [3]Ctr. for Neurosci. Studies, Queen's Univ., Kingston, ON, Canada; [4]IoNS, Univ. Catholique De Louvain, Louvain-la-Neuve, Belgium

Abstract: In many situations, we manipulate objects grasped away from their center of mass, which induces torques applied tangentially to the grip surfaces when the object is accelerated. When the object configuration induces a tangential torque relative to the grip axis, we previously showed that the grip force exhibits a gradual and slow decrease as subjects learned to manipulate the unbalanced object (Crevecoeur et al. 2011). The specific contribution of a tangential torque in the sensorimotor control of grip force remains unexplored and very hard to dissociate from usual loads experienced during object manipulation.
To investigate this issue, we asked six naive human subjects to perform vertical point-to-point arm movements in the weightless conditions induced by parabolic flight. The weightless condition presents the advantage to remove gravitational forces, thereby isolating the effect of inertial forces in the control of grip force (GF). Participants were holding an instrumented object with an off-center precision grip (mass 360 g, including an 40 g mass placed 10 cm away from the grip), thus inducing tangential torques. They performed the task only during the micro-gravity phase (22 seconds) of 30 parabolas each. Four target LEDs were placed along a vertical structure. The program generated a random sequence of targets at a frequency of 1Hz. They were asked to move to and stabilize the object at the current target as fast as possible until the next target was illuminated.
Such movements typically presented static and dynamic phases that permit a distinction to be made between a static and dynamic component of the GF. The static component of the GF used during the five first parabolas was high (above 20 N). We observed a gradual decrease of this component across the parabolas with a stabilization between the fifth and the tenth parabolas. In spite of similar adaptation rate, the average static grip force across the five last parabolas (around 10 N) were much higher than during static phases of similar movements made in absence of a tangential torque (Crevecoeur et al. 2009). Hence, 0-g specific adaptation was unchanged across

conditions including or not the presence of a tangential torque. Furthermore, within each parabola, subjects seemed also to stabilize the static component of the GF after 5 movements. Finally, we observed a modulation of the dynamic component of the grip force that was scaled to the tangential torque loads. These results demonstrate that inertially-generated torque loads contribute to the higher level of static grip force that characterize manipulation of an unbalanced object.

Title: Movements should be slower on Moon than on Mars

Authors: *V. THEATE[1], P. LEFÈVRE[1], J.-L. THONNARD[2]
[1]ICTEAM / IONS, [2]IONS, Univ. Catholique De Louvain, Brussels, Belgium

Abstract: Slower movements in weightlessness and faster movements in hyper-gravity have already been observed. However, few studies have investigated the effect of partial gravity on human movements and especially on oscillatory movements. In this study, we investigated the influence of the gravity level on periodic movements and then we focused on the underlying motor control.
The dynamics of precision grip, the kinematics and the muscular activities of the upper limb have been investigated in six subjects performing oscillations of their right arm in Lunar gravity (0.16g), Martian gravity (0.38g), Microgravity (0g) and Hyper-gravity (1.6g). Subjects were asked to perform oscillations of the upper limb spontaneously at their most comfortable

frequency. These oscillations were executed between two LED targets with the arm extended (Figure 1). Results showed that for most of the subjects the grip force was better coordinated with the load force under Lunar and Martian gravity than under Microgravity. We also observed that the oscillation periods decreased as the level of gravity increased from 0.16g to 1.6g. Interestingly, it was not the case in Microgravity (Figure 2). In addition, time varying activities of the Deltoid and the Latissimus Dorsi muscles were observed through the different levels of gravity. The movement slowing down as well as the changes in muscular activity enable a decrease of the overall joint impedance when the gravity level decreases. The analysed process of the muscular activity emphasized that the Central Nervous System optimizes the control by modulating the frequency of the oscillations in function of gravity. Our results also showed that the case of weightlessness is singular, confirming previous results (White, 2008) supporting that a central pattern generator issued from the spine regulates the frequency of an oscillatory movement in the absence of gravity.

Title: Cortical electrophysiological representation of hand gestures: A human ECoG study decoding sensorimotor function

Authors: *M. BLEICHNER, Z. V. FREUDENBURG, M. J. VANSTEENSEL, E. J. AARNOUTSE, F. S. S. LEIJTEN, N. F. RAMSEY

Univ. Med. Ctr. Utrecht, Dept. of Neurol. and Neurosurg., Rudolf Magnus Inst. of Neurosci., Utrecht, Netherlands

Abstract: From electrostimulation, lesion and imaging studies it is known that our hands and fingers are topographically represented on the motor and sensory cortex. Using electrocorticography (ECoG) it has been shown that it is possible to distinguish the movement of individual fingers. However, complex hand movements as they are used for example in sign languages have gained little attention so far. While much is known about the language aspect of sign language the motor representation of complex hand gestures has not been studied thoroughly.
Here, we address the question of how complex hand gestures are electrophysiologically represented on the sensorimotor cortex and investigate the possibility to differentiate hand gestures.
Five patients, undergoing epilepsy surgery and naïve to sign language, were implanted with high-density subdural electrode grids (32 electrodes, 1.3 mm exposed surface, inter electrode distance 3 mm center to center) for one week. The electrodes were placed over the central sulcus covering pre- and postcentral areas where the hand function was expected (based on preoperative fMRI). Patients were asked to perform four hand gestures taken from the American Sign Language alphabet. Each gesture was repeated 10 times in a randomized order. A data glove measuring the bending of each finger verified the correct execution of the gestures.
Data was epoched into individual trials and corrected for movement onset. The power in the 65Hz to 95Hz range was computed for all electrodes for a 2000ms window around movement onset. A matched filter leave-one-out classification was performed for each dataset. Classification accuracy varied between 65% and 95% (chance level 25%).
We conclude that the surface of the sensorimotor cortex shows a gesture-selective pattern of high-frequency-band activity.
The classification accuracy depended on the position of the electrodes: as expected the most informative electrodes were located on M1 hand knob. On average ten adjacent electrodes were sufficient to reach the best classification result.
We showed here that classification of complex hand gestures is possible using high-density grids located on the motor and sensory cortex. A very simple and straightforward classification procedure was sufficient to achieve optimal results in some cases. The information used for classification was comprised to a small area of cortex.
Our findings have important implications for the decodability of imagined/attempted gestures for multiclass brain computer interface (BCI) control in paralyzed people.

Title: Anticipatory and reactive grip force modulation during object handover

Authors: *S. ENDO, A. M. WING
Dept. of Psychology, The Univ. of Birmingham, Birmingham, United Kingdom

Abstract: Passing an object to another person is a commonly performed motor task. During the transfer, the motor commands need to be scaled, not only with respect to the dynamics of the object, but also to those of the receiver. To achieve a smooth object transfer with limited time available for sensory feedback correction, learning and predicting the task partner's movement becomes important. The present study investigated contributions of interpersonal anticipatory and online control in transferring an object from one person to another.
Pairs of participants (passer and receiver) were instructed to transfer an object as they would naturally perform the task while sitting. In Standard trials, the receiver (a confederate of the experiment) accepted the object from the passer as naturally as possible. In Perturbation trials, the receiver lightly placed the index and middle fingers and the thumb on the object (< 1 N) but did not exert sufficient force to support the object alone. There were 180 Standard trials and 20 randomly occurring Perturbation trials. Grip force (normal to the grasp surfaces) and the interaction force of the pair (longitudinal force between the partners) were measured using three 6 DoF force/torque sensors embedded in a custom-made plastic housing. The total weight of the object was approximately 150 g.
The results showed concurrent grip force modulation by the passer and receiver. As the passer reduced grip force, the receiver increased the grip force, keeping the net grip force between the pair at a similar level in the Standard trials. The cross-correlation function further revealed a slight lead of the Passer in modulating grip force. In Perturbation trials, the passer successfully detected the lack of grasping by the receiver and readjusted the grip force within 150 ms after the first contact, highlighting the online motor correction by the passer to counteract a motor error of the receiver. Furthermore, detailed analysis showed a difference in the motor strategy before and after the perturbation such that the grip force modulations of the partners became more sequential with smaller force used by the passing partner at the next trial after perturbation. Nevertheless, there was quick learning and these measures returned to baseline within 3-4 trials.
These results indicate that the grip force modulations during object transfer involve both anticipatory and feedback control in case of unexpected event. Furthermore, unexpected grasping control by a receiver affects the subsequent grasping of the passer. In conclusion, the present

study highlights the role of feedforward and feedback mechanisms in grip force modulation during interpersonal object transfer.

Title: Hand muscle activity for digital coarticulation in pianists

Authors: *S. A. WINGES, S. FURUYA, M. FLANDERS
Neurosci, Univ. Minnesota, MINNEAPOLIS, MN

Abstract: Highly trained pianists are capable of individual finger movements that reflect their enhanced ability to restrict movement and force production of non-striking digits. Examinations of the kinematics of professional pianists have revealed that for individual keystrokes, the movement of the striking digit is consistent while the movement of non-striking digits varies depending on prior and subsequent keystrokes. With training, enhanced motor cortical excitability and plasticity has been observed during finger movements. However, at the neuromuscular level, the patterns of muscle activation that accompany these complex movement patterns are not known.

The purpose of this study was to characterize the temporal waveforms of multi-muscle activation patterns in highly trained pianists. Ten subjects (4 Male; 35±10 yrs) were included in the study. Each subject performed 14 different musical scores that required the use of the right hand. Prior to data recording for each new score, subjects were allowed to practice the musical score in order to play consistently and accurately. Each of the 14 scores was played for 10 successful trials at a normal tempo (125 ms ISI) provided by a metronome. Surface EMG was recorded from three portions of extrinsic finger muscles: a central portion of extensor digitorum (ED) and two portions of flexor digitorum superficialis, one closer to the middle finger (FDS) and the other closer to the ring finger (FDS2). Surface EMG was also recorded from two intrinsic thumb muscles: abductor pollicis brevis (APB) and flexor pollicis brevis (FPB), as well as two intrinsic finger muscles: first dorsal interosseus (FDI), and abductor digiti minimi (ADM).

Patterns of muscle activity were examined using Principal Component Analysis (PCA) and cluster analysis. Two to four PCs were required to account for 75% of the variance in the

patterns of muscle activity for an individual striking digit. For all subjects, thumb strikes required only two or three PCs. For individual finger strikes, the need for higher order PCs varied across subjects such that the professional pianists within our sample tended to require more PCs to account for the same amount of variance. Therefore, when performing the same keystrokes, professional pianists used more variable patterns of muscle activation, which were described by higher order PCs. Clustering patterns of muscle activity according to fingering sequences also revealed differences that may reflect the use of more complex patterns of coarticulation by the professional pianists.

Title: Partial transfer of dexterous manipulation across hands reveals limited generalization of learned object dynamics

Authors: *J. Y. CHOI, M. JESUNATHADAS, M. SANTELLO
Sch. of Biol. and Hlth. Systems Engin., Arizona State Univ., Tempe, AZ

Abstract: The extent to which learned dexterous manipulations can be transferred across hands is not well understood. We asked subjects to learn two-digit manipulation of an object with an asymmetrical CM (left or right CM) after which they either translated the object (Experiment 1), or translated and rotated the object (Experiment 2) to the contralateral hand. For Experiment 1, subjects had to exert T*com* in the same direction (object-frame of reference) with both hands, whereas for Experiment 2 they had to exert T*com* in opposite directions. Each experiment consisted of 8 consecutive trials followed by one trial where the object was either translated (T) or translated and rotated (T+R). This sequence was repeated four times. For both experiments, based on previous work on grasping at constrained contacts we hypothesized that initially subjects would be able to transfer the direction but not the magnitude of T*com* on the first post-T or –T+R trial. We further hypothesized that subjects would learn to transfer both T*com* magnitude and direction with further practice with object T and T+R.

We found that subjects failed to transfer learned manipulation on the first trial with the contralateral hand. Specifically, T*com* on the first post-T and post-T+R trial was significantly smaller (on average, 15% and 10%, respectively) then T*com* on the preceding trial ($P < 0.05$). However, for both experiments, subjects exerted T*com* in the direction appropriate to CM location (McNemar's test). Specifically, when comparing pre- vs. first post-T trial, direction of T*com* was not significantly different ($P > 0.05$) whereas pre-T+R and first post-T+R trial revealed a significantly different T*com* direction ($P < 0.05$). By the 4th T and T+R trial, the magnitude of T*com* was statistically indistinguishable from T*com* exerted at the end of the first sequence of consecutive trials ($P > 0.05$) and also exerted in the direction appropriate to CM location ($P > 0.05$, $P < 0.05$; Experiment 1 and 2, respectively).
These findings indicate that subjects correctly identified the object mass distribution but could not transfer the magnitude of T*com*. However, after further practice with object T and T+R, subjects might have been able to retrieve sensorimotor memory of previous manipulations and plan manipulation accordingly despite having to transfer or rotate T*com* direction, respectively.

Title: Sophistication of dexterous finger movements through daily piano practice

Authors: *A. NAKAMURA[1], T. GODA[1], H. MIWA[1], N. NAGATA[1], S. FURUYA[2]
[1]Kwansei Gakuin Univ., Sanda, Hyogo, Japan; [2]Hannover Univ. of Music, Drama, and Media, Hannover, Germany

Abstract: Plasticity of the nervous system enables skilled hand movements following training and rehabilitation. Previous studies that compared pianists and non-musicians have demonstrated that extensive piano practice elicits structural and functional changes in motor-related brain regions, which endows dexterous finger movements. However, little has been understood about the causal relationship between piano practice and hand motor functions. The present longitudinal study aimed to straightforwardly determine effects of daily piano practice on hand motor functions such as speed, accuracy, and independence of finger movements. Six right-handed adult participants with no history of piano playing were asked to play a short tone sequence consisting of twelve strokes with the left hand synchronized with a metronome (two

strokes per second) for fifty trials per day over four successive days. Before and after four-days of practice, several tests to assess fundamental hand motor functions were carried out. Timing and velocity information of each keypress was collected from an electric piano. Thirteen high-speed cameras also recorded finger movements, and flexion/extension joint angles at the metacarpo-phalangeal, proximal-phalangeal, and distal-phalangeal joints were computed at the index, middle, ring and little fingers. Surface EMG was recorded from the extrinsic finger flexor and extensor muscles. Following the practice, the participants exhibited a significant decrease in temporal variability of keystrokes, indicating improved accuracy of finger movements. During playing the trained sequence as fast as possible, the maximum rate of keystrokes also increased after the practice, confirming enhancement of finger movement speed. The untrained right hand also showed improvement of both accuracy and speed following the left-hand practice, which suggests a transfer effect of uni-manual practice on the contra-lateral hand. A fastest finger tapping test, which required repetitive and fastest keystrokes by one finger with keeping the remaining digits depressing the adjacent keys, demonstrated an improvement in maximum movement rate following the practice at each of all fingers except for the ring finger. This suggests different plasticity across fingers in terms of independent control. A correlation analysis of movements across fingers supported for this view by demonstrating non-uniform improvements of movement independence across fingers following the practice. Finally, the finger muscular coactivation decreased with daily practice, presumably reflecting minimization process of energetic cost of movements.

Title: Role of online visual feedback on digit force-position coordination for dexterous manipulation.

Authors: A. BOSCO[1], Q. FU[2], N. GAW[2], *P. FATTORI[1], M. SANTELLO[2]
[1]Dept. di Fisiologia Umana e Generale, Universita' di Bologna, Bologna, Italy; [2]Arizona State Univ., Tempe, AZ

Abstract: We studied the effect of online visual feedback on subjects' ability to perform dexterous manipulation. The manipulation consisted of grasping and lifting an object straight by counteracting an external torque caused by a mass added to the left or right of the object base. Three groups of subjects (group 1 = 6; group 2 = 9; group 3 = 10) were tested in one of three experimental conditions: (1) "No vision", (2) "No vision - 10 cm", and (3) "No vision - 20 cm". For conditions (2) and (3), vision of the hand and object during the reach was removed when the hand crossed a distance of 10 and 20 cm from the object, respectively. For condition (1), vision of hand and object was removed at reach onset. We quantified the effect of removing visual feedback on peak object roll, the torque exerted at object lift onset required to counter the external torque on the object (compensatory torque), vertical distance between thumb and index finger center of pressure, and grip and load forces. Subjects learned to minimize object roll in the "full vision" condition after 4 trials, after which peak object roll and compensatory torque remained relatively invariant. All subjects of group (2) and (3) were able to generate a suitable compensatory torque in both of these partial vision conditions. In contrast, group (1) presented a significantly higher compensatory torque in the "No vision" condition ($P<0.05$). No significant differences were found for the other variables for group (2), whereas group (3) exhibited larger grip and smaller load forces in no vision trials ($P < 0.05$). Lastly, no vision trials from groups (1)-(3) showed a significantly larger number of peaks in grip force derivative compared with the vision condition ($P<0.05$). This preliminary analysis suggests that online visual feedback is particularly important for the early phases of force development following contact. Nevertheless, tactile and proprioceptive feedback is sufficient to enable subsequent modulation of fingertip forces as a function of digit placement for object manipulation.

Title: Frictional interactions in the contact zone of the finger pad before and during slipping.

Authors: *J.-L. THONNARD[1], B. DELHAYE[2], T. ANDRÉ[1], P. LEFÈVRE[2]
[1]Inst. of Neurosci., Univ. Catholique De Louvain, Brussels, Belgium; [2]Inst. of Information and Communication Technologies, Electronics and Applied Mathematics, Brussels, Belgium

Abstract: Grip function depends on the neurophysiological response to frictional interactions in the contact zone of the finger pad. The early adjustment to a new frictional condition, which may appear soon after the object is initially touched (ca. 0.1-0.2 s), depends on the vigorous responses of the mechanoreceptors. In order to prevent slip, the grip/load force ratio must exceed a minimal value determined by the coefficient of friction between the skin and the object, i.e. the critical ratio at which the slip occurs. The initial slip of a finger pad occurs by the propagation of an annulus of failure from the perimeter of the contact zone to its center, and this phenomenon, namely the incipient slip, is of importance in grip function. In this presentation, we will describe the complex skin movements observed during the transition from a stuck state to a fully developed slip, and the dependency of these events on skin hydration. Skin deformation inside the contact region was imaged with an optical apparatus that allowed us to quantify the relative sizes of the slipping and sticking regions. The ratio of the stuck skin area to the total contact area decreased from 1 to 0 when the tangential force component increased from 0 to a maximum. The slope of this relationship was inversely correlated to the normal force component. The skin hydration level dramatically affected the dynamics of the contact encapsulated in the course of evolution from sticking to slipping. The specific effect of moisture was to reduce the tendency of a contact to slip. In conclusion, a better knowledge of the fingertip skin deformation before and during slipping may contribute to understand how we can prevent the objects from slipping during their manipulation.

Title: Effect of visual feedback information on interpersonal force production

Authors: *M. O. ABE[1], K. WATANABE[1,2]
[1]The Univ. of Tokyo / Res. Ctr. For Advanced Sci. and Technol., Tokyo, Japan; [2]Japan Sci. and Technol. Agency, Saitama, Japan

Abstract: In human motor system, visual feedback plays an important role for updating the system and for maintaining the optimal performance. Previous studies on continuous force matching tasks demonstrated that the force was decreased exponentially within a few seconds after the removal of visual feedback information. This phenomenon was considered as reflecting a decay of visuomotor memory and was found both in unilateral and bimanual conditions. While these conditions involved intrapersonal organization of the performance, few studies have yet examined modulation of the force production in the interpersonal condition. This study examined how visual feedback information would affect a continuous force production task when the tasks were performed interpersonally.
Ten pairs (20 participants) performed continuous force production tasks, the goal of which was to match continuous forces exerted by the index finger on a given target force as accurately as possible for 20 seconds. Participants did this by observing two cursors representing each force (single condition) or one cursor representing the force averaged from the pair (joint condition). These tasks were performed under three visual feedback conditions: full visual feedback, no visual feedback, and pseudo visual feedback. In no visual feedback condition, visual feedback on the force level was withdrawn for the last 10 seconds of each trial. In pseudo visual feedback condition, the participants observed pseudo signals that were similar to their preceding signals under full visual feedback but the force was not reflected. The pseudo signals were created by surrogating methods in which the phases in frequency domain were randomized. Few participants recognized those as ‘pseudo’ signals in the experiment. The pairs performed four sets of the above conditions with a rest. Force modulation was evaluated by comparing the averaged force for the final two seconds with the force for two seconds before the visual conditions were imposed.
The results showed differential modulations of the force production among visual feedback conditions. Under no visual feedback condition, force decay was shown both in the single and joint condition and there was no significant difference between the two conditions. In contrast, pseudo signals induced increases of the force in the single condition and the degree was larger than that in the joint condition. These results suggest that the effect of visual feedback information on continuous force production depends on whether the production is performed individually or jointly.

Title: Differences of manual grasping in a typical laboratory and in an everyday-like scenario

Authors: *O. L. BOCK, F. STEINBERG
German Sport Univ., Koln, Germany

Abstract: We have shown before that grasping movements from the same starting point to the same object of interest exhibit different kinematic and dynamic properties when they are executed in a typical laboratory context versus in an everyday-like scenario; those differences could be reduced to five orthogonal factors. The present experiments explore possible reasons for this observation.
In Exp. 1, we found that different grasping factors correlate with different cognitive abilities, namely, with overall psychomotor speed, attention focussing and a preference for controlled processing.. Exp. 2 yielded that withdrawing attention increased, and a higher task complexity decreased the context-dependence for one of the grasping factors.
The presence of factor-specific effects provides external validity to the view that contextual cues affect multiple sensorimotor processing stages. More specifically, the pattern of findings suggests that those stages are differentially sensitive to the speed, complexity and attentional load of a task. Possibly, these task characteristics modulate the distribution of sensorimotor processing between the ventral and the dorsal occipito-frontal stream.

Title: Effect of cold-induced shivering on precision grip

Authors: *M.-A. IMBEAULT[1,2], R. BALASUBRAMANIAM[3], F. HAMAN[1,2]
[1]Human Kinetics, Univ. of Ottawa, Ottawa, ON, Canada; [2]Unité de Recherche sur la Nutr. et le

Métabolisme, Inst. de Recherche de l'Hôpital Montfort, Ottawa, ON, Canada; [3]Kinesiology, McMaster Univ., Hamilton, ON, Canada

Abstract: The aim of the study was to investigate the effects of cold-induced shivering intensity on precision grip. Using a liquid-conditioned suit, six non-acclimatized men had their whole body (except for hands, feet and face) exposed to cold (4ºC) for 90 minutes. Precision grip tasks (object manipulation) were performed before and after 90 min of cold exposure. In the object manipulation task, participants were asked to lift an object (250g) and either maintain it stationary or oscillate the object vertically for 20 sec. Shivering intensity (3.7 ± 0.5 %MVC) and oxygen consumption increased significantly (p= 0.0009) during cold exposures while core temperature remained stable throughout exposure. Skin and finger temperatures significantly decreased by 7 ± 0.2 ºC and 10 ± 0.7 ºC, respectively, during cold exposure compared to baseline ($p < 0.0001$). After cold exposure, grip force: load force ratio (GF:LF ratio) in both stationary and oscillatory tasks were 60 ± 22 % and 35 ± 11 % higher compared to baseline values (p= 0.05 and p= 0.04, respectively. No significant correlation was observed between shivering intensity and the increase of GF:LF ratio(%) but a strong correlation was observed between skin temperature and the % increase of GF:LF ratio in the oscillatory task ($r^2 = 0.77$, $p = 0.02$). These results suggest that despite no direct exposition of the hands, the sensorimotor control of precision grip was impaired after 90 min of cold exposure and skin temperature seems to be a good indicator of the alteration.

Title: Modulation of resting state and task-related activity by bihemispheric motor cortex stimulation in older adults

Authors: R. LINDENBERG[1], L. NACHTIGALL[1], M. MEINZER[1], *A. FLOEL[2]
[1]Neurol., Charite Univ. Med., Berlin, Germany; [2]Charite Universitätsmedizin Berlin, Muenster, Germany

Abstract: Bihemispheric transcranial direct current stimulation (“dual” tDCS) of primary motor cortices has been described to enhance motor learning in healthy subjects and to facilitate motor recovery after stroke. In order to investigate the neural correlates of its mode of action, we

compared different tDCS montages in a group of healthy older adults in a cross-over design (‘dual’ vs. ‘anodal’ vs. ‘sham’).
20 subjects (mean age 68.7±4.7 years, all right-handed) underwent tDCS and simultaneous MRI at 3T, including resting state fMRI and a choice reaction time task. In the task, subjects were presented with different symbols in a randomized order and required to respond with button presses using either left or right index fingers. In both active stimulation conditions, the anode was placed over left primary motor cortex (M1). The cathode was positioned over right M1 (‘dual’) or the contralateral supraorbital region (‘anodal’). The current was constantly delivered during resting state and task-related fMRI. Task-related fMRI analysis was carried out with SPM8; resting state data were analyzed with Lipsia using low-frequency spectral Eigenvector Centrality Mapping (ECM).
In the task-specific fMRI analysis, an effect of stimulation condition became apparent: When subjects tapped with their right index finger, beta values of both left and right M1 were significantly higher in the ‘dual’ condition when compared to ‘anodal’ and ‘sham’; the latter conditions did not differ from one another. When subjects tapped with their left index finger, ‘dual’ yielded an elevation and ‘anodal’ yielded a reduction of beta values in bilateral M1 as compared to ‘sham’. In the resting state analysis, ECM values in the left dorsolateral prefrontal cortex (DLPFC) and posterior cingulate cortex were higher in the ‘dual’ condition as compared to ‘sham’; in contrast, ‘dual’ yielded significantly lower values in the right insula. ‘Anodal’ showed higher ECM values in the left DLPFC as well as left ventral premotor cortex when compared with ‘sham’; lower ECM values were found in the left precuneus (all $p<.001$, Monte Carlo-corrected).In conclusion, tDCS induced specific changes of M1 activation in the task-specific fMRI. As a complement, the resting state analysis demonstrated altered connectivity within a multimodal network including non-primary motor cortices as well as prefrontal and parietal regions, indicating that the previously documented stronger behavioral effects of dual as compared to anodal tDCS may not be merely mediated by a “simple” add-on effect of cathodal stimulation, but rather due to complex bihemispheric network modulations.

Title: An evolutionary account of handedness

Authors: *C. L. GONZALEZ, T. RUTSCHMANN, J. W. FLINDALL
Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Many theories have been put forward to explain the origins of right-handedness in humans. Here we present evidence that this preference might have emerged from a right hand advantage in grasping objects for feeding. Fifteen participants were asked to pick up food items of 3 different sizes: Cheerios® (avg. 11 mm in diameter), Froot Loops® (avg. 15 mm), and Oatmeal Squares (avg. 21 mm). Participants used their right- and their left-hands in two separate blocks (50 trials each, starting order counterbalanced) to pick up the items. Within each block participants were asked to either eat the food item or to place it inside the pouch of a bib worn beneath their chin (25 trials of each, blocked design). The bib condition was included to ensure that the outward and inward trajectories were similar to the eating condition, but removing the final step of placing the food inside the mouth. Participants wore PLATO liquid crystal goggles that blocked their vision between trials. Each trial began with the goggles switching from opaque to clear. After 1000 ms of full vision, participants were cued to reach by an auditory cue (i.e., 'beep'). All trials were conducted in closed-loop with 5000 ms of vision before the goggles switched to opaque, at which time the experimenter placed a new food item for the next trial. Hand kinematics were recorded by an Optotrak Certus (NDI, Waterloo, ON, Canada), which tracked the three-dimensional position of three infrared light-emitting diodes attached separately to the index finger, thumb, and wrist. We found a hand (left/right) by action (eat/bib) interaction in the maximum grip aperture (MGA; the maximum distance between the index finger and thumb achieved in flight prior to the grasp). MGAs were smaller in the right hand but only when picking up the items with the intent to eat them. In fact, follow up t-test show that the right-hand/eat condition was significantly different from all other conditions which in turn did not differ among themselves. Because smaller grip apertures are typically associated with greater precision, our results demonstrate a right hand advantage for grasping objects to eat. From an evolutionary perspective it would make sense to resort to the hand that could grasp food with more precision maximizing the chances of successful retrieval, consumption, and thus, survival. If the right hand is better equipped for that task (as shown here), this could explain in part how we became right-handed.

Title: The time course of corticospinal excitability during action observation is consistent with a muscle, but not goal or kinematic based mechanism

Authors: *S. MC CABE[1], G. SAUNIER[2], J. I. VILLALTA[1], S. T. GRAFTON[3], V. DELLA-MAGGIORE[1]
[1]Physiol. of Action Lab- Sch. of Medicine- Univ. of Buenos Aires, Ciudad Autonoma De Buenos Aires, Argentina; [2]Ctr. de Ciências da Saúde- Lab. de Neurobiologia II, Univ. Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Dept. of Psychology, Univ. of California, Santa Barbara, CA

Abstract: Passive observation of another person executing an action activates the motor system of the observer. This phenomenon, known as motor resonance, can be inferred based on the modulation of the corticospinal excitability (CSE) using transcranial magnetic stimulation. Previous studies have proposed that motor resonance reflects the activity of the muscles involved in the different phases of the action (e.g. Fadiga et al, 1995), its goal (e.g. Cattaneo et al, 2009) or its kinematics (e.g. Gangitano et al, 2001). It has also been postulated that changes in the time course of CSE reflect the prediction of future action phases (Urgesi et al, 2010). Distinguishing among these alternative accounts is difficult, since most of these studies used a unique goal or measured the level of CSE solely at the point of maximal muscle contraction or maximal aperture, and often during observation of static pictures. We aimed to further discern among these possible mechanisms by measuring the time course of CSE during the observation of grasping movements aimed at two targets of different sizes. We ran experiment 1 to have a precise description of the kinematics and muscle activity during normal execution of a grasping action. Extensor Indicis Proprius (EIP) was mostly active during hand aperture, whereas First Dorsal Interosseus (FDI) was mostly active during hand closure when approaching the target. ADM showed no significant temporal modulation. In experiment 2 we filmed videos of the same grasping movements with natural velocity (~1 sec) and selected 4 time points to characterize the time course of CSE during observation. To allow full prediction of the action to be observed, we indicated the target of the grasp action before each trial. Consistent with the muscular activity measured during execution, the observation related CSE for the FDI was maximal when the hand closed to grasp the object but minimal at maximal hand aperture. Observation CSE for the EIP correlated positively with hand aperture for the large object but showed no modulation for the small object. The ADM showed no temporal modulation. Our findings favor the hypothesis that motor resonance reflects muscle activity and not the movement's kinematics. In addition, the

temporal matching between CSE and muscle activity goes against the anticipatory simulation hypothesis, nor does it support the goal hypothesis since the goal of the action was known before movement onset. We conclude that when goal information is provided, motor resonance elicited by unperturbed actions reflects muscle activity. We are currently assessing the effect of goal uncertainty on the time course of motor resonance.

Title: Grasping without reaching: A kinematic analysis of vision, demand, and hand-use manipulations in right- and left-handers.

Authors: *J. W. FLINDALL, T. RUTSCHMANN, J. B. DOAN, C. L. R. GONZALEZ
Kinesiology, Univ. of Lethbridge, Lethbridge, AB, Canada

Abstract: Manual prehension can be defined in terms of two separate components; a reaching component, and a grasping component. Behavioural and imaging studies have shown that these components are programmed individually by separate neural circuits and then integrated into a single movement. While reaching kinematics have been described in depth, isolating the grasping component from the reach is more challenging; how does one grasp something without first reaching toward it? In the current study we attempted to separate the grasp from the reach. Participants were asked to grasp a glass of water located 4cm beneath a fixed starting position (a 1x1 cm rigid body suspended from a wire attached to a 25x25 cm wooden platform). With this manipulation all outward reaching motion normally accomplished via flexion/extension of the distal muscles of the forearm and wrist was replaced with minor flexion of the proximal muscles of the shoulder. Right- (n=12, 7 females) and left-handers (n=10, 5 females) grasped empty and full glasses of water, with right and left hands, under closed-loop, open-loop, and open-loop delay visual conditions. Kinematic analysis shows that both right and left-handers respond similarly to manipulations of vision (both groups demonstrated more accurate maximum grip apertures in closed-loop compared to open-loop and delay conditions, and time to grasp increases as visual feedback is reduced), demand (both groups complete grasps towards empty glasses

significantly quicker than grasps toward full glasses), and hand (reaction times towards empty glasses are significantly shorter than those towards full glasses, but only when participants used their right hands). Our results suggest that, like those for reaching and grasping, the neural processes responsible for planning and executing grasping alone are susceptible to manipulations of both visual feedback and task demand. Notably however, unlike those associated with reaching alone, the effects described herein appear to be independent of handedness.

Title: The effects of task and skill on sequentially produced grasp forces

Authors: K. A. DELAVE[1], J. M. LANGAN[2], K. L. KERN[1], *S. H. BROWN[1]
[1]Sch. of Kinesiology, Univ. of Michigan, ANN ARBOR, MI; [2]Rehabil. Sci., SUNY Buffalo, Buffalo, NY

Abstract: The control of grasp force is influenced by multiple factors such as task, skill, force level and the direction of force change - i.e. increasing or decreasing forces. Specifically, static force production has been shown to be more variable at higher force levels (Newell et al.,1984; Slifkin et al., 1995), and there is evidence that controlled force release is not only more rapid but also more variable compared to increasing force tasks (Masumoto & Unui, 2010). Practice/skill level reduces variability (Semmler & Nordstrom, 1998; Voelcker-Rehage & Alberts, 2005) and may be effective as a rehabilitation tool (Kim et al, 2010). In order to determine the applicability of a visual force feedback system for training purposes, this study examined the effects of task (unilateral vs bilateral), skill level (competitive Ultimate Frisbee players vs controls), and force direction, on whole-hand isometric grasp forces.
Using handheld dynamometers, grasp force was visually displayed as vertical bars on a computer screen. Target zones representing 5-20% of each participant's maximum voluntary contraction were superimposed upon the force display. Participants either increased or decreased force in a sequential "stair-stepping" pattern (0-5%, 5-10%, 10-15% 15-20%, 20-15%, 15-10%, 10-5%, and 5-0% MVC) as fast and accurately as possible and then held the force in the target zone for 3 s. The task was performed both unilaterally and bilaterally. The rate of force change (df/dt) was

higher during controlled force release compared to force generation ($p<.01$) but only during unilateral force tasks. No effect of force direction was observed in bilateral tasks. Changes in force level occurred more slowly in bilateral compared to unilateral tasks ($p<.01$). In contrast to predictions, skill level had no effect on df/dt in either task. Force variability was greatest following changes at the lowest force levels (0 to 5% or 10 to 5%), but, otherwise, was relatively constant. Variability was unaffected by task or direction of force change. As with df/dt, no differences related to skill level were observed.
The lack of skill-related differences was unexpected given the need for precise grasp force control in elite Frisbee players but may be related to the role visual feedback plays in controlling forces (Kennedy & Christou, 2011). It is possible that group differences may occur in tasks where target forces are established proprioceptively. The observation that variability was highest at the lowest force level contrasts with previous reports. To what extent these conflicting findings relate to differences in isometric force paradigms or the range of forces examined requires further clarification.

Title: Sense of effort revisited: Relative contribution of sensory feedback and efference copy

Authors: *S. SCOTLAND[1], D. E. ADAMO[2], B. J. MARTIN[1]
[1]Univ. of Michigan, Ann Arbor, MI; [2]Wayne State Univ., Detroit, MI

Abstract: We have shown that the sense of effort is asymmetric in the upper limbs and suggested that a difference in gain (input/output magnitude relationship) between each limb/hemisphere system may explain this asymmetry. The aim of this study was to investigate further the relative contribution of the efference copy and sensory feedback to the sense of effort, which is still being debated. Twenty- two (17 F and 5 M) right-handed, young healthy individuals performed grasp force matching tasks while seated in a standard posture with their forearms supported. Horizontal cylinders instrumented with strain gauges and placed next to each other at elbow level were grasped in pronation. The matching task consisted of reproducing

a 20% MVC reference, set by the right or left hand, with the same (ipsilatateral remembered, IR) or contralateral (contralateral remembered, CR) hand, with/without reference force visual feedback and with/without reference hand vibration (60Hz, applied to wrist flexor tendon). No feedback was provided for the matching hand. A marker controlled by the reference force signal, presented on a vertical scale displayed on a video screen, provided visual feedback. In the absence of this visual feedback the reference force was learned from verbal qualitative feedback. To minimize asymmetry issues the results focus on the absolute matching error (AE) expressed in %MVC. It was found that AE was greater without than with visual feedback. In the no visual reference condition, AE was greater without than with vibration, while vibration had no effect when the visual reference was provided. The results indicate that visual feedback was associated with the resultant grasp force, which represents the system output or summation of motor commands. This association was not observed in a similar but abbreviated experiment in which learning might not have occurred. The influence of vibration-induced alteration of sensory information observed only in the absence of visual feedback indicates that the utilization of sensory and /or efferent copy information is context dependent. The smaller AE observed when the reference hand is vibrated is assumed to be only an apparent error reduction resulting from the complex interaction of a TVR and the reweighting of agonist-antagonist commands used to reproduce the reference force output. Overall these results underline a major role of the efference copy in the sense of effort.

Title: The speed of voluntary movements modulates interhemispheric inhibitory interactions between primary motor cortices

Authors: *T. TAZOE[1,2,3], M. A. PEREZ[2]
[1]Dept. of Rehabil. for Movement Functions, Res. Institute, Natl. Rehabil. Ctr. For Persons With Disabilities, Tokorozawa, Japan; [2]Systems Neurosci. Institue, Ctr. for the Neural Basis of Cognition, Univ. of Pittsburgh, Pittsburgh, PA; [3]Japan Society for the Promotion of Sci., Tokyo, Japan

Abstract: Animal research has suggested that callosal neurons contribute to encode the time of behavioral events (Soteropoulos and Baker 2007). However, their role during human voluntary movement remains poorly understood. The aim of our study was to investigate the ipsilateral silent period (iSP, a measure of callosal interhemispheric inhibition) during movements of different speeds and durations. We used single pulse transcranial magnetic stimulation to elicit the iSP in an intrinsic finger and an elbow flexor muscle during continuous index finger abduction and adduction movements and during continuous elbow flexion and extension movements executed at fast (1 Hz) and slow (0.25 Hz) speeds. The left side completed the task while the contralateral side remained at rest (unimanual) or conducted a mirror-like (bimanual) movement. The iSP was measured as a transient suppression in electromyographic (EMG) activity in the left first dorsal interosseous and biceps brachii muscle, respectively. We found that the iSP was greater during fast compared to slow movements in all conditions tested in both muscles. We also examined the iSP during discrete index finger abducion and elbow flexion movements completed at fast (ballistic) and slow (self-paced) speeds. Here, we found that the iSP was increased during ballistic compared to self-paced movements in both muscles tested. Additional control experiments demonstrated that that the iSP remained similar at increasing levels of isometric voluntary contractions. Our findings demonstrate that the strength of interhemispheric inhibition between primary motor cortices is influenced by the speed of distal and proximal arm movements regardless of movement duration and background EMG activity. These observations suggest a role for callosal pathways in signaling the speed of a movement.

Title: Intermuscular coherence between hand and arm muscles during bilateral contractions in humans

Authors: D. S. SOTEROPOULOS[1], *M. A. PEREZ[2]
[1]Inst. of Neurosci., Newcastle Univ., Newcastle, United Kingdom; [2]Dept. of Physical Med. and Rehabil., Ctr. for the Neural Basis of Cognition, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Most of our daily activities involve coordinated muscle activation of hand and arm muscles. How corticospinal drive to muscles of the hand and arm interact during unilateral and bilateral voluntary contractions remains poorly understood. We examined coherence between electromyographic
(EMG) signals at frequencies between 15 to 35 Hz which is thought to indicate common drive to two muscles from corticospinal inputs. We recorded from the first dorsal interosseous (FDI), abductor pollicis brevis (APB), flexor carpis radialis (FCR), and biceps brachii (BB) muscles during unilateral and bilateral simultaneous elbow flexion and precision grip. Testing was completed when the non-dominant arm performed a precision grip and elbow flexion while the contralateral arm remained at rest or performed the same motor task. We found that during unilateral contractions mean coherence in the 15-30 Hz range was present to a largest extent between adjacent pairs of muscles such as FDI-APB, FDI-FCR and FCR-BB compared to distant muscle pairs such as FDI-BB and APB-BB. Mean coherence in the 15-30 Hz range between all muscle combinations tested was decreased (by 9% to 47%) during bilateral compared to unilateral contractions. In distant muscle pairs, the largest decrease in mean coherence was between APB-BB (by 41%) than FDI-BB (by 9%) during bilateral compared to unilateral contractions. These findings show task-dependent interactions between bilateral distal and proximal arm muscles during voluntary contractions in humans, and indicate that the decreased oscillatory muscle to muscle coupling may be part of the adaptations taking place to coordinate bilateral activation of different muscle groups.

Title: Effects of unilateral voluntary movement on the firing rate of motor units on the contralateral side

Authors: H. OHTSUKA[1], T. NAKAJIMA[2], S. SUZUKI[3], G. FUTATSUBASHI[3], E. SHIMIZU[1], *T. KOMIYAMA[4]
[1]Chiba Univ. Grad. Sch. of Med., Dept. of Cognitive Behavioral Physiol., Chiba City, Japan;

[2]Dept. of Integrative Physiol, Kyorin Univ. of Sch. of Med., Tokyo, Japan; [3]The United Grad. Sch. of Edu., Tokyo Gakugei Univ., Tokyo, Japan; [4]Chiba Univ., Chiba City, Japan

Abstract: Voluntary contraction of a muscle often generates electromyographic (EMG) activity in the homologous muscle on the opposite side (mirror-like activity), not only in pathological states but also in healthy adults. This is thought to be a default neural system which decreases with age. Interestingly, it was also reported that the amplitude of motor evoked potentials after transcranial magnetic stimulation were suppressed in concert with the onset of contraction of the contralateral homologous muscle. These findings suggest that the descending command responsible for mirror-like activity contains both excitatory and inhibitory effects on spinal motoneurons. Therefore, the purpose of the present study was to reveal the nature of descending inputs to motoneurons during mirror-like activity with a peri-movement time histogram of single motor unit (MU) activity.

Nine healthy volunteers participated in the experiment, and all gave written informed consent. Surface EMGs were recorded from the left and right first dorsal interosseous (FDI), and single MU activity was recorded with a fine needle electrode from the left FDI by weak isometric abduction of the index finger. Subjects performed phasic abduction of the right index finger during a visual reaction time task. The intensity of the right index isometric abduction was set at 2, 10, and 40% MVC; these values were displayed on an oscilloscope in front of the subject. At the same time, the subjects were instructed to maintain a given range (~8 - 10 Hz) of firing rate of MU in the left FDI with auditory and visual feedback. The peri-movement time histogram of MU discharge activity was constructed by calculating the number of discharges recorded during 30~50 trials with 10ms bins.

Modulation of the firing rate of MU activity in the left FDI was observed in conjunction with the onset of right index finger movement. However, changes in the firing rate of MU were strongly dependent on the exerted force level of the right index finger. An increase in the firing probability was more frequently observed during 40% MVC (15/18 units in 9 subjects) than 2% (5/18 units in 9 subjects) and 10% MVC (8/15 units in 9 subjects). In addition, although significant increases of the cumulative sum of MU firing (100 ms window) calculated from peri-movement time histograms were observed during 40% MVC, significant decreases in those were observed during 2% MVC. These findings led us to conclude that the spinal motoneurons receive both excitatory and inhibitory inputs depending on the force level of the contralateral finger.

Title: Interhemispheric differences in stimulus-response profiles for the contralateral and ipsilateral silent period in young healthy adults

Authors: *T. DAVIDSON[1,3], M. GERGUIS[1], F. TREMBLAY[3,2]
[1]Sch. of Human Kinetics, [2]Sch. of Rehabil., Univ. of Ottawa, Ottawa, ON, Canada; [3]Bruyère Res. Inst., Ottawa, ON, Canada

Abstract: The contralateral (cSP) and ispsilateral silent period and (iSP) derived from transcranial magnetic stimulation (TMS) can be used to probe the excitability of inhibitory circuits in the human motor cortex. Previous investigations have shown that the duration of both cSP and iSP are influenced by the intensity of stimulation (Chen, Yung, & Li, 2003, J Neurophysiol). However, few studies have compared hemispheric differences in cortical responsiveness to increasing TMS intensity using the cSP and iSP, as index of intra- and interhemispheric inhibition. In the present study, we investigated this issue in young healthy adults (n=6) who were strongly right lateralized. Participants underwent TMS of each hemisphere (order counterbalanced) using a Magstim 200 stimulator connected to a figure of eight coil. Motor evoked potentials (MEPs) were recorded from each hand with surface electrodes placed over the first dorsal interosseous (FDI). On each hemisphere, cSP and iSP were tested at 4 different intensities relative to the resting motor threshold (i.e., 110, 120,130 & 140% rMT). In each trial (3 s), TMS was delivered (2.5 s delay) to the hemisphere ispsilateral to the maximally contracting hand (iSP, squeezing a vigorimeter) while the opposite hand was lightly contracting (cSP, pinch-grip). The durations of the silent periods were determined by visual inspection of EMG traces on a trial by trial basis. A 2x2 repeated measures ANOVA found a large main effect ($p<0.001$) for “intensity” but no effect of “hand/hemisphere” for both cSP and iSP measurements. The intensity effect reflected the lengthening of both the iSP and cSP in response to increasing TMS intensity. Further post-test comparisons with pooled data from both hand/hemispheres revealed that cSP had significantly ($p=0.001$) steeper stimulus-response profile than iSP (mean slope, iSP, 0.44±0.01; cSP, 2.02±0.13). Our findings demonstrate that hemispheric dominance Is not a major factor in influencing iSP and cSP measurements while intensity relative to the RMT remains a critical parameter. Such findings have implications for studies examining the impact of exercises or interventions using silent periods as index of intra- and interhemispheric changes in motor excitability.

Title: Enhancing excitability of the primary motor cortex: A TMS study exploring contributions from transcallosal connections and non-primary motor cortices

Authors: *R. J. IBEY[1], W. R. STAINES[1,2]
[1]Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada; [2]Sunnybrook Hlth. Sci. Ctr., Heart and Stroke Fndn. Ctr. for Stroke Recovery, Toronto, ON, Canada

Abstract: In primates, control of the distal muscles of the upper limb was thought to be regulated by the contralateral motor system and devoid of transcallosal connections between the individual primary motor cortical (M1) representations. More recent research with primates and humans has demonstrated increased ipsilateral motor cortical activity during unimanual movements. Transcranial magnetic stimulation (TMS) studies reveal increased corticospinal tract activation to the resting homologous muscle with contraction and rhythmical movement. A recent study in our lab demonstrated that extensor carpi radialis (ECR) M1 excitability was increased during a muscle contraction independent of the effector--i.e. homologous muscle contraction increased excitability to the same degree as contralateral dorsiflexion (DF). Within M1 there is no overlap of arm and leg representations, therefore there must be inputs from non-primary motor regions that contribute to this interaction. The purpose of this study was to investigate the non-M1 contributions to excitability of M1. We hypothesized that excitability of M1 ipsilateral to the contracting upper limb ($M1_{ipsi}$) would be enhanced during wrist-ankle movement and non-primary motor areas would influence this up-regulation. We delivered focal transcranial magnetic stimulation to healthy right-handed subjects targeting the M1 representation of the right ECR muscle during isometric and isotonic (rhythmical) contractions of the left ECR and flexor carpi radialis (FCR) and right and left DF and plantarflexors (PF) at 10% and 30% of their maximum voluntary contraction. Both isometric and isotonic conditions were performed for each of these conditions: (1) left wrist flexion/extension, (2) left wrist flexion/extension and left ankle DF/PF, and (3) left wrist flexion/extension and right ankle DF/PF. Motor evoked potentials (MEPs) were recorded using surface EMG from ECR, FCR, DF and PF bilaterally. Subjects were positioned with their left arm and left and right legs secured in a manipulandum that allowed for either full wrist flexion/extension or ankle PF/DF. They monitored their level of contraction on a computer screen placed in front of them during each

trial. Twenty MEPs were sampled over M1 during each condition. We sampled MEPs during the pre-movement phase as well as during the movements. Preliminary results suggest $M1_{ipsi}$ excitability is enhanced during isodirectional movements (i.e. ankle DF and wrist extension) when the left wrist is active with the right or left ankle simultaneously. These results suggest that the non-primary motor areas are responsible for this interaction, thereby influencing M1 excitability.

Title: Continuous theta burst stimulation (cTBS) to the right primary motor cortex (rM1) and short-term bimanual training modulates the excitability of the left M1 (lM1).

Authors: *J. L. NEVA[1], M. VESIA[2,3], J. S. THAKER[2], W. R. STAINES[2,3]
[1]Dept. of Kinesiology, [2]Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada; [3]Sunnybrook Hlth. Sci. Ctr., Heart and Stroke Fndn. Ctr. for Stroke Recovery, Toronto, ON, Canada

Abstract: Activity in cortical areas underlying motor preparation and execution is enhanced after a single session of bimanual visuomotor training. These adaptations occur specifically when training requires simultaneous activation of homologous muscles and is characterized by an increase in the cortical territory occupied by the trained muscles within the primary motor cortex (M1) [Neva et al, 2012 Neurosci Letts]. This modulation may include connectivity with both premotor regions and interhemispheric interactions between homologous muscle representations in M1. Continuous theta burst stimulation (cTBS) to M1 suppresses motor evoked potentials (MEPs) from the stimulated M1 [Huang et al., 2005 Neuron]. Few studies suggest that cTBS to rM1 increases corticospinal activity in lM1[Suppa et al., 2008 J Physiol]. Also, motor function of the affected limb improves in stroke patients after applying cTBS to the contralesional M1 or S1 in combination with movement training [Meehan et al., 2011 Neurosci Letts]. This study investigates the effects of cTBS to rM1 on wrist extensor representation in lM1, and its potential combined effects with short-term bimanual training. This experiment tests the hypothesis that cTBS to rM1 will increase excitability of the extensor carpi radialis (ECR) in lM1, and the addition of bimanual training will cause a greater increase. ECR representations in lM1 were

measured in 2 groups before and after (1) cTBS over rM1 and (2) cTBS over rM1 combined with bimanual training. Following cTBS over rM1 the lM1 representation of ECR was acquired over multiple time periods separated by ~30min. lM1 ECR representation was determined by acquiring MEPs (n=10) from several positions separated by 1cm centred over the hotspot. The borders of the representation were defined as the sites where MEPs were no longer observed. Neuronavigation using anatomical images was used to guide the TMS coil over the motor hotspot and ensure reproducibility of sampled sites. Single-pulse TMS was delivered at an intensity of 110% of resting motor threshold. cTBS was delivered to rM1 ECR representation at 80% of active motor threshold. Preliminary analysis indicates that ECR representation in lM1 is facilitated after cTBS over rM1. This facilitation post-cTBS to rM1 alone is observed in both central and global MEP amplitude. The combined effect of cTBS over rM1 with bimanual training on lM1 shows an increase in spatial extent with a modest increase in global MEP amplitude. These results suggest that modulation of one M1 may alleviate ongoing interhemispheric inhibition (or increase facilitation) to the opposite M1 in healthy individuals via transcallosal or subcortical connections.

Title: Activity of spinal interneurones during movements with left or right hand.

Authors: *D. S. SOTEROPOULOS[1], S. BAKER[2]
[1]Inst. Neurosci, [2]Newcastle Univ., Newcastle Upon Tyne, United Kingdom

Abstract: Far from being a blind servant to cortical control, the spinal cord moulds descending and peripheral signals to drive motoneurones in the pattern required for a given movement. The spinal cord is bilaterally organised both in its descending inputs from cerebral cortex areas and brainstem but also in its peripheral inputs and local circuits (e.g. the spinal commissural system). Despite this bilateral anatomic connectivity and its importance for locomotory movements, it is unclear how primate spinal circuits on one side of the cord modulate their activity during goal

directed movements of the contralateral arm.
Extracellular neural recordings were made from spinal interneurones in an awake behaving macaque monkey performing a "reach to grasp" task with either hand. The monkey initiated the trials by placing each hand on a homepad; following a delay (~500ms) and a laterality cue (~750ms, tone), plastic flags occluding the task retracted for the cued manipulandum. The monkey then reached out and performed a precision grip with the index finger and thumb (auxotonic with left hand , isometric with right), while the non moving hand remained at rest on the homepad. Following a 1s holding period, a food reward was given. Ninety three interneurones were recorded from the intermediate laminae in the left and right lower cervical spinal cord during this task. Single pulse stimulation at these sites (bi-phasic, 0.2ms per phase, intensity 5 to 200 μA) primarily elicited finger and wrist movements.
Cell activity was quantified as mean firing rates during resting both hands on the home pads, the reach and squeeze phase (500ms window just before the grip hold period) and the 1s-long hold period. The majority of the neurones showed a significant firing rate modulation during movements of the ipsilateral arm compared to the home pad epoch (72/93 cells) - this was either during the reach and squeeze phase only (17/72 cells), hold phase only (12/72cells), or both phases (43/72). A large fraction (45/93) of cells also modulated their activity during movements of the contralateral arm (reach and squeeze:13, hold:8, both:24). Of those cells, eleven showed a significant modulation only with movements of the contralateral arm. Cells showed a rate increase (51/72) or decrease (21/72) relative to the homepad epoch for ipsilateral movements. In the case of cells modulating with both hands, the direction of rate change was similar between the two sides in 18/34 cells and different for 16/34.
Our results show that spinal circuits show a diverse modulation of activity during movements with the opposite arm. The relative contribution of descending, peripheral and local signals remains to be determined.

Title: Rhythmical bimanual force production: 1:2 and 2:3 coordination patterns

Authors: *D. M. KENNEDY, J. B. BOYLE, C. H. SHEA
Dept. of Hlth. & Kinesiology, Texas A&M Univ., College Station, TX

Abstract: A large number of experiments over the last 40 years have isolated a coalition of constraints, including cortical and subcortical neural crosstalk, that influence the coordination of the two hands functioning together. Recent findings, however, have demonstrated that these constraints are eliminated or at least minimized when integrated feedback (e.g., Lissajous feedback) is used. Two experiments were designed to determine participants' ability to coordinate 1:2 (N=8, Experiment 1) and 2:3 (N=8, Experiment 2) rhythmical bimanual force production tasks. We hypothesized that neural crosstalk should be more easily detected and characterized in tasks where the forces required to produce the goal pattern of coordination are increased than in tasks where force requirements are minimal. The task was to rhythmically produce a pattern of isometric forces on a left side force transducer with the left arm that was coordinated with the pattern of isometric forces produced on a right sided force transducer with the right arm. The Lissajous display involved a goal template and a cursor indicating the forces produced with both limbs. The cursor moved from left to right as force was produced with the right arm and from bottom to top as force was produced by the right arm. The template illustrated the specific pattern of force requirements needed to produce the goal coordination pattern. The results indicated very effective temporal performance of the bimanual coordination patterns. This result is similar to that observed in our earlier work with reciprocal and circling motion, but is especially informative given that the increased forces required to produce the desired bimanual coordination pattern resulted in a consistent and identifiable distortion of the left limb forces that could be attributable to the production of right hand forces. We were not able to detect distortions of the forces produced by the right limb that could be attributable to the left limb. This type of right to left limb influence, which may be attributable to asymmetrical cortical and subcortical crosstalk, was not evident in our earlier work when the bimanual coordination tasks involved movements of the limbs in a relatively frictionless environment.

Title: Kinematic properties of the upper and lower arms during bimanual grasping

Authors: *A. LE[1], J. C. DESSING[2], J. D. CRAWFORD[2], M. NIEMEIER[1,2]
[1]Univ. of Toronto Scarborough, Scarborough, ON, Canada; [2]Ctr. for Vision Research, York Univ., Toronto, ON, Canada

Abstract: Grasping an object with two limbs is phylogenetically older than the hand, yet bimanual grasping is rarely studied. It is of particular interest because it involves lateralized visual object analysis in one hemisphere to program the grasp (Le et al., SfN, 2011) together with bimanual coordination of the two hands through the two hemispheres. To better understand the processes underlying this coordination, here we examined the kinematic rules of the two arms during bimanual grasping. In particular, the goal was to investigate how the two hands are coordinated, how the torsional demands of the two upper and lower arms interact, and whether the arms maintain Donders' Law. To this end we asked 15 subjects to use both hands to horizontally grasp a rectangular object that was presented in one of 15 locations (5 locations left to right of body midline, at 3 heights), and lift it off a pedestal. We found that as the object was placed more eccentrically, the two hands maintained a high correlation in trajectories. Nevertheless, the ipsilateral hand trajectories became more curved before object contact and the contralateral hand trajectories became more linear, as expected given that grasp trajectories have to avoid unwanted contact with the front face of the object. Perhaps as a consequence we found that the ensuing lift-off trajectories of the object were more variable for more eccentric object locations suggesting that the grasp was less stable at these locations. Another factor of reduced stability could be that eccentric object locations were biomechanically more challenging. However, this was not reflected in the 3D rotations of the two arms. That is, we found that the two arms did not show eccentricity effects in their torsional rotations and level of adherence to Donders' law. Consistent with this, we found that regardless of the eccentric location of the object, (a) the torsional rotations of two arms were always negatively correlated, (b) the lower arms had more torsional rotation than the upper arm (especially as the objects were more elevated), and thus (c) the upper arms adhered more closely to the Donders' Law than the lower arms. These observations suggest that although the grasp is less stable when bimanually grasping eccentrically located objects, the two hands and arms follow coordinated bimanual kinematic rules regardless of object's location, with the upper arms closely adhering to Donders' law and the lower arms accounting for most of the required torsional rotation. This research sheds new light on the coordinated kinematics of the two arms during bimanual grasping. Future studies will use these data to identify and monitor motor problems in patients with motor deficits.

Title: Altered agonist muscle activation explains impaired endpoint accuracy during goal-directed movements of the ankle in children

Authors: *E. J. FOX, M. KWON, Y.-T. CHEN, M. COSTANZO, H. MORA, K. SOWALSKY, E. A. CHRISTOU
Univ. of Florida, Gainesville, FL

Abstract: It is well-known that children exhibit impaired movement control compared with adults. Nonetheless, the ability of children to perform discrete goal-directed movements of the ankle is not well-understood. Accuracy during goal-directed movements of the ankle is a critical component of daily activities and is a requisite for mobility and gait adaptations. The purpose of this study was to compare movement accuracy and variability as well as the activation of agonist and antagonist muscles in young adults and children during goal-directed movements of the ankle. Ten young adults (20.0 ± 0.9 yrs, 4 males) and 7 children (9.7 ± 0.8 yrs, 5 males) participated in a single test session. Subjects attempted to accurately match the peak displacement of the foot to a spatiotemporal target by performing an ankle dorsiflexion movement. The targeted displacement (spatial) was 9° of ankle dorsiflexion and the targeted time (temporal) was 180 ms. Subjects received visual feedback for 5 s after each trial. Surface EMGs were recorded from the tibilis anterior (agonist) and soleus (antagonist) muscles. Endpoint accuracy was quantified as the overall error, which was calculated from the orthogonal relationship of the position and time errors (absolute deviation from the target). Endpoint variability was calculated as the coefficient of variation across trials for the peak displacement and time to peak displacement. Children exhibited greater overall error as well as greater temporal error and positional variability compared with young adults ($P < 0.05$). The amplitude of tibialis anterior muscle was greater in children ($P < 0.05$), but the duration of activation and the time to peak activation was shorter. The amplitude of soleus activation also was greater in children. The greater overall error and temporal error in children was predicted by the duration of the agonist muscle ($R2 = 0.72$ and 0.62, respectively). In conclusion, compared with young adults, children were less accurate during goal-directed movements of the ankle and differences were largely explained by altered activation of the agonist muscle. The muscle activation differences may be due to immaturity of the cortico-motor systems in children. Understanding motor control in healthy children is critical so that findings may be applied to the study of children with neuromuscular impairments.

Title: In search of manual asymmetries in aging during complex tasks: Does upper limb performance become more symmetric with age?

Authors: T. LULIC, A. ENGELHARDT, C. R. DICKERSON, *E. A. ROY
Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Abstract: Handedness is defined as the tendency to prefer one arm to the other in performing daily motor tasks. Age-related reduction in hemispheric lateralization and simple motor tasks is known to occur in older adults (Cabeza et al., 2002; Przybyla et al., 2011). This study sought to identify potential reductions in manual asymmetries in older adults (OA) when performing more complex upper limb tasks, such in completing activities of daily living (ADLs). A secondary goal was to identify the influence of aging on dominant and non-dominant spatial and temporal aspects of movement during these tasks.
Methods: Upper limb and trunk movements of 8 healthy, older (67.25 ± 4.5; 2M, 6F) and 6 healthy, younger, right-handed adults (YA) (23.16 ± 0.93; 3M, 3F) were captured at 100 Hz via a motion capture system (Vicon, Oxford, UK). Forty-three reflective markers were placed on anatomical landmarks of the upper limbs and trunk. Participants performed two task types: 1) pantomiming a gesture (e.g. slicing an imaginary loaf of bread with imaginary knife) in 9 ADLs; and 2) gesturing while holding a physical tool in the nine ADLs. Tasks and ADLs were block randomized by limb, with each gesture performed three times by both limbs. The movement was divided into three phases: reach to grasp, tool use, and termination phase.
Results: The data analysis revealed no hand effects and no interaction of hand with age. There were, however, age effects on performance. Specifically, when looking at the entire movement cycle the OA demonstrated shorter cycle duration with no difference in extension/flexion at the elbow. When focusing just on the forward movement of the cycle, wrist amplitude was shorter for the OA and they demonstrated higher peak velocities and less time after peak velocity.
Conclusion: Overall, the current study found no differences in performance between limbs. However, there was an effect of age which suggested a difference in movement control. The time to complete the movement cycle was shorter for the OA which appeared due to a smaller movement amplitude, a higher PV and less time spent processing feedback in the deceleration phase of the movement. This pattern suggests that the OA may have been using a more ballistic

mode of control. Interestingly while movement amplitude was larger for the YA, the ROM at the elbow did not differ, suggesting that more of the movement was being controlled at the shoulder in this group. The implications of these findings for understanding movement disorders in stroke such as apraxia will be discussed.

Title: Method to redistribute effort during multi-limb rehabilitation exercise through implicit feedback

Authors: N. E. SKINNER[1], *A. D. KUO[2]
[1]Mechanical Engin., Univ. of Michigan, Ann Arbor, MI; [2]Univ. Michigan, Ann Arbor, MI

Abstract: Humans sometimes exercise in a way that is easier in the short term but poorer for long-term goals. Those recovering from stroke or spinal cord injury may favor the limbs most needing exercise to prevent long-term disuse. One solution is to provide patients with explicit feedback of limb use during multi-limb exercise. This may, however, also add to cognitive demand.
We propose an alternative approach, termed implicit task weighting. We alter the power feedback normally displayed during exercise, by unequally weighting a targeted set of limbs. We hypothesize that humans determine their preferred distribution of limb effort based on relative ease. Here we test if implicit weightings, by distorting relative ease, can alter the distribution of limb effort. We also test whether this has lower cognitive burden compared to explicit feedback.
We compared implicit and explicit feedback during multi-limb exercise performed by young healthy adults (N = 16). We instrumented a NuStep recumbent stepper to measure the power produced by individual limbs, which all act against a single load. For implicit testing, we displayed a weighted power meter to subjects, without informing them of the weighting. To test explicit feedback, subjects viewed bar graphs separately displaying both the total power and the distribution of effort between arms and legs. We tested both conditions with and without a secondary cognitive task, a simple subtraction series.
Results showed that both implicit and explicit feedback can steer effort, altering a person's

preferred distribution by 25-30% toward either the arms or legs. With implicit feedback, subjects reached the power goal with less error compared to explicit feedback ($P<0.001$). This difference was not affected by the cognitive task ($P<0.001$). Subjects performed the cognitive task 5% slower when using explicit feedback compared to implicit ($P=0.03$).
Implicit task weighting may provide a simple means to encourage use of targeted limbs during exercise. It may also require less attention than explicit feedback.

Title: Motor costs and control policies in the healthy and parkinsonian brains

Authors: *R. SHADMEHR[1], Y. SALIMPOUR[1], Z. MARI[2]
[1]Dept Biomed. Eng, [2]Dept Neurol., Johns Hopkins Univ., BALTIMORE, MD

Abstract: There are often multiple ways to perform an action. The choices that people make are a window to how their brain evaluates costs of the task. In Parkinson's disease (PD), people exhibit bradykinesia in their affected limbs. A recent report suggests that this behavior is not due to an inability to accurately use the affected side, but rather due to an abnormally increased motor cost (Mazzoni et al. 2007). Here, we performed an experiment to quantify motor costs in PD. We considered an isometric task in which people held two force transducers, one in each hand. The goal was to use the left and right arms in such a way as to move a cursor toward targets distributed around a circle. The position of the cursor was the sum of the force produced by each arm. For each target the subjects chose how much force to produce with each arm. This choice was direction dependent, but remarkably consistent over repeated days. We hypothesized that the choice was due to a cost that had two components: a cost for variability (how well they can control each arm), and a cost for effort (strength of each arm). To measure variability, in a unimanual task we measured variance of force for each arm at each direction of force. To measure effort, we measured the maximum voluntary force for each arm and each direction.

Despite the fact that the choices that healthy (n=8) and PD patients (n=8) made in the bimanual task were fundamentally different, both choices were well described by the sum of variance and

effort costs. PD patients had increased variance for extensors on the affected side as compared to controls, and this accounted for the fact that in the bimanual task they tended to rely on the arm that had lower variance for directions that it tended to flex. Therefore, we found that the cost functions in PD and controls were similar: both avoided actions that produced higher variance. The main difference was that PD suffered from significantly increased variance on the affected side, mainly for actions that produced extension.
Next we applied anodal tDCS to M1 of the affected hemisphere of PD patients. This produced an immediate reduction in variance on the affected side in the unimanual task. Remarkably, this also made the choices of PD patients in the bimanual task more similar to healthy controls. In summary, we found that choices that PD patients make in their actions are due to a cost that has two components: variance, and effort. On the affected side, variance is significantly increased with respect to controls, and the choices of PD patients are generally consistent with this increased variance. We can improve unimanual variance of the PD patients using tDCS. This produces an immediate improvement in their actions in bimanual tasks.

Title: Alternate-hand training for recovery of post-stroke dexterity

Authors: *V. M. ALURU[1,3,4], D. GELLER[2], M. WILSON[6], S. KASTUAR[7], P. RAGHAVAN[5]
[1]Rehabil. Med., [2]NYU Langone Med. Ctr., New York, NY; [3]NYU Langone Med. center, New York, NY; [5]Rehabil. Med., [4]Rusk Inst. of Rehabil. Med., New York, NY; [6]Hunter Col., New York, NY; [7]New York Univ., New York, NY

Abstract: Post-stroke recovery is thought to occur due to re-organization of preserved neural substrate, and the unaffected hemisphere shows increased task-related activation after stroke. However it is not known if the unaffected hemisphere takes over, detracting from recovery of the affected hand, or if it can assist in its recovery through transfer of sensory-motor information across the hemispheres. We performed a pilot study to test the efficacy of alternate-hand training where the unaffected hand “teaches” the affected hand. Six subjects with post stroke hemipaersis participated in the study. Sensory-motor impairment, hand function and modulation of precision

grasp were measured prior to and following eight 45-minute sessions of alternate-hand training over 4 weeks. The training consisted of grasping and releasing objects alternatively, first with the non-involved hand and then with the involved hand, with the tasks progressing in difficulty across the sessions. The subjects consistently improved on upper limb joint proprioception, tests of higher order sensory integration (sterognosis and 2-Point discrimination) and pinch strength. Functional ability improved specifically on tasks which required precision grasp. Execution of precision grasp, measured with the preload phase duration, showed a consistent decrease across all subjects suggesting improved grasp stability and grip-load coordination. Subjects that showed impaired predictive control of fingertip forces and excessive grip forces also improved both on the affected and unaffected sides. Our results suggest that alternate-hand training can improve sensorimotor integration and hand function in subjects with chronic post stroke hemipaersis. The mechanisms by which this transfer of information occurs across hemispheres needs further investigation.

Abstract: Few options exist for training arm movements in subjects with severe post-stroke hemiplegia. We designed a series of bimanual mechanical devices which link movements of the two sides so that movement of the unaffected side produces homologous movements on the

affected side. The utility of these devices lies in the ability of the patient to repeatedly move the affected body part without assistance from a therapist, providing the opportunity to maintain and/or increase range of motion and awareness in the affected limb, limit spasticity, contracture, and deformity, as well as gain a sense of control over their own rehabilitation. However, it is not known if movements of the unaffected side compete with or enhance movements on the affected side. We tested the efficacy of training with 4 devices which were designed to produce movements opposite to the typical post-stroke synergy patterns. Training involved (1) shoulder external rotation and elbow extension, (2) supination, (3) wrist extension and (4) finger extension either in a proximal-to-distal order or vice versa. Eight subjects with chronic post-stroke hemiplegia participated in the study. Subjects received 1.5 hours of training twice a week for 6 weeks. Motion analysis was used pre- and post-training to assess for increase or decrease in active range of motion (AROM). On average, patients showed improvements on the Fugl-Meyer (FM) score, although patients who trained distal-to-proximal showed greater improvements in wrist and hand FM scores. All subjects improved in one or more practiced directions on the affected side. Interestingly, although the unaffected side was the driver for the training sessions, there was some reduction in AROM on the unaffected side. The results suggest that simultaneous bimanual training can enhance active movement on the affected side even in individuals with chronic post-stroke hemiplegia, perhaps by recruiting redundant ipsilateral pathways.

Title: Elucidating the basis of personalized protocols for post stroke rehabilitation

Authors: *P. RAGHAVAN[1], V. ALURU[2], Y. LU[3]
[1]Rehabil. Med., New York Univ. Langone Med. Ctr., NEW YORK, NY; [2]Rusk Institute, New York Univ. Med. Ctr., New York, NY; [3]Ctr. for the Promotion of Res. Involving Innovative Statistical, NYU, New York, NY

Abstract: A stroke affecting the motor system leads to limited movement which can be due to varying degree of weakness, lack of selective control and spasticity. Decreased motivation to move may further impede movement. How these variables interact with each other to inform treatment is not known, but this information is critical to providing appropriate rehabilitation interventions. Here we had 21 subjects with post-stroke hemiparesis perform 18 trials of a wrist flexion-extension task for 15 seconds, where they performed 2 trials with both hands (bimanual) for every one trial with the affected hand (unimanual). We examined the learning effect of the bimanual trials on the unimanual trials in terms of wrist range-of-motion (ROM), and activity in the wrist flexors and extensors. We also examined the influence of auditory emotional (happy sounds), musical (up tempo self-selected music), and rhythmic (metronome beat at preferred rate) stimuli on learning. Based on their ROM, relative strength of wrist flexors (F) and extensors (E), and their co-activation (F/E ratio) at baseline trials, the subjects were clustered into those with (1) weakness (very low ROM, low extensor strength and high co-activation- F/E ratio>1), (2) spastic-co-contraction (low ROM, high extensor strength and high co-activation), (3) new learners (moderate ROM, high extensor strength and moderate co-activation-F/E ratio > 0.6), and (4) efficient learners (high ROM, high extensor strength and low co-activation). We found that only subjects with very low and low ROM (clusters 1 and 2) showed consistent bimanual-to-unimanual learning effect. Happy sounds increased ROM in all groups except the efficient learners (cluster 4), and the increase was correlated with individual emotional intelligence scores. Music increased ROM in the low and moderate ROM group (clusters 1 and 3), and the increase was correlated with baseline depression scores. Rhythm increased ROM variably, but particularly in those with spastic co-contraction (cluster 2), and the improvement was correlated with Fugl Meyer scores. The learning effect on ROM was mediated by differential effects of the stimuli on flexor and extensor activity in the various subject clusters. The results demonstrate that the treatment (bimanual) effect varies by extent of weakness and spasticity at the individual level, and that personalized auditory stimuli can modulate motor performance and learning. The results lay the foundation for personalized protocols for post-stroke rehabilitation.

Abstract: The conditioning effect of motor tasks upon lumbar spinal reflex activity in humans has been extensively studied using H-reflex activity and recurrent inhibition during antidromic motor volleys [1]. These methodologies test only one or two spinal cord segments while the conditioning motor tasks used with these reflexes are multisegmental events. The method of transcutaneously evoking posterior root-muscle (PRM) reflexes simultaneously in several segments can give insight into the motor control in humans with intact and disordered nervous system function [2-3].

We demonstrate the application of testing motor behavior expressed by multisegmental PRM reflex activity conditioned by volitional motor tasks in human subjects with an intact nervous system. Single- and multi-joint motor tasks of the lower limbs are performed in the supine, sitting and standing position in order to learn not only the conditioning effects on PRM reflexes but also the role of posture on the motor behavior of spinal reflex activity.

The excitability of spinal motor nuclei can be modified by the supraspinal motor control of spinal interneuronal circuits. Our hypothesis is that premotor spinal cord processing expresses the pattern of descending engagement of interneuronal pools. The pattern of distribution of segmental motor behavior during fundamentally different motor tasks (single- vs. multi-joint) suggests dynamic modifications of inhibitory and excitatory actions of spinal interneurons.

We are expanding our study to also test the interneuronal engagement by sustained electrical stimulation of peripheral nerves. Thus, we will be able to report on differences between spinal interneuronal processing features elicited by central motor tasks and by peripheral nerves inputs.

Title: ERP components during motor preparation predict subsequent reaching movement velocity and accuracy under risk and uncertainty

Authors: *M. PLANK[1], S. HILLYARD[3], J. SNIDER[1], H. C. HUANG[2], S. GEPSHTEIN[4], H. POIZNER[1]
[1]Inst. for Neural Computation, [2]Dept. of Cognitive Sci., Univ. of California San Diego, La Jolla, CA; [3]Dept. of Neurosci., UC San Diego, La Jolla, CA; [4]Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: Accurate reaching movements towards spatial targets require the proper interaction of sensory, motor, motivational and memory systems during both motor planning and execution. While brain areas involved in reach-related actions have been identified in humans and nonhuman primates, EEG dynamics associated with efficient and accurate reaching are only beginning to be examined. We studied the spatio-temporal EEG characteristics during reach planning of spatially targeted vs. non-targeted 3D hand and eye movements, and how EEG parameters associated with sensory processing and multimodal transformation were modulated by the amount of eye-hand coordination required for the subsequent reaching movement. Facing a vertical touch screen, healthy participants performed a total of 1100 trials of time-constrained reaching movements with their dominant hand from the screen center towards lateral targets. Hits, misses and time-outs (responses exceeding a time constraint) yielded monetary gains or losses. Subjects were allowed to move both hand and eyes or only their hand following a 500-

700ms delay interval during which the hand and gaze remained on a center fixation cross. An additional condition involved a non-spatially-directed hand “lift” movement from the screen. Synchronized 72-channel scalp EEG, eye tracking and optoelectronic finger/hand/arm motion recordings were obtained from 10 subjects. Extending previous research (Trommershauser et al., 2003), reaching accuracy, the 2D distance between hand endpoint and target center, decreased when subjects were required to fixate the screen center compared to when they were free to make saccades (10.0 ± 1.3 mm vs. 6.9 ± 1.2 mm, respectively; $p < .001$). Moreover, the amplitude of the P300, an ERP component associated with allocation of attentional resources, was markedly higher during the delay interval when subsequent eye/hand movements were directed towards a spatial target compared to non-targeted hand lifts. Furthermore, amplitude modulations of ERP components associated with early visuo-spatial processing (N170, P2) and attentional allocation (P300) significantly correlated with subsequent behavioral performance both in terms of reach accuracy and precision, and with kinematic parameters such as movement velocity and acceleration. The correlations were strongest over right parietal and bilateral frontal regions (r’s > 0.60, all p-values $< .05$). Thus, ERPs recorded over right parietal and bilateral frontal cortices within three hundred milliseconds following the onset of a spatial target predict subsequent movement accuracy and aspects of the upcoming kinematics.

Title: Age-difference in the functional role of premotor and primary motor regions during response preparation

Authors: *H. FUJIYAMA, M. R. HINDER, J. J. SUMMERS
Sch. of Psychology, Univ. of Tasmania, Hobart, Australia

Abstract: *Background.* The modulation of interhemispheric inhibition (IHI) between two motor regions during movement preparation is suggested to be instrumental for the production of unimanual responses by suppressing activation in the non-responding hand. Particularly, the left dorsal premotor cortex (PMd) appears to play a key role in the preparation of response of either

hand. Our preliminary work has indicated that older adults have a greater reliance on left PMd regions during the preparation of simple motor actions than younger adults. An association between a release of left PMd–right primary motor cortex (M1) inhibition and faster reaction times (RT) was evident in older adults in a simple RT task using the left index finger. Here we investigated the functional role of PMd and M1for both left (Exp1) and right (Exp2) hemispheres during response preparation in younger and older adults using double pulse transcranial magnetic stimulation (TMS) 'virtual-lesion' protocol (10 ms interstimulus interval, 110% resting motor threshold).
Methods. Younger and older adults performed a simple RT task abducting their left index finger as fast as possible in response to an imperative signal (IS) presented 500 ms following a warning signal (WS). TMS was applied to PMd and M1 at seven times during response preparation/execution. In Exp 1 TMS was delivered to the left hemisphere, while motor regions in the right hemisphere were stimulated in Exp 2. In each experiment, TMS was also delivered to the vertex (Cz) as a control.
Results. Both younger and older adults responded faster following PMd (left & right) and Cz TMS, particularly when delivered during the preparatory period, relative to baseline RT (obtained in the trials without TMS), indicating a non-specific intersensory facilitation effect. M1 TMS in the involved right cortex resulted in an overall RT delay in young adults, while non-involved left M1 disruption did not modulate RT. In older adults, the left M1 disruption during the preparatory period and right M1 disruption during response generation delayed RT, suggesting a differential time-course of functional involvement of left and right M1 during response preparation and generation in older adults.

Title: Corticomuscular coupling slows reaction time of ballistic new movement

Authors: *R. MATSUYA[1], J. USHIYAMA[1,2], J. USHIBA[3,2]
[1]Keio Univ. Grad. Sch. of Sci. and Technol., Kanagawa, Japan; [2]Keio Univ. Sch. of medicine, Tokyo, Japan; [3]Keio Univ. Fac. of Sci. and Technol., Kanagawa, Japan

Abstract: Oscillatory activity of the sensorimotor cortex shows coherence with muscle activity within the 15-35 Hz band (β-band) during tonic isometric voluntary contraction. Previous numerous cross-sectional studies have reported that the magnitude of the corticomuscular coherence can differ according to various factors, such as neurological disorders, sports experience, habitude, and aging. Recently, we have reported that magnitude of corticomuscular coherence varies among individuals even within healthy young adults. Especially in the subjects showing greater coherence, prominent grouped discharge is observed in the electromyogram (EMG) signals. We hypothesized that such difference in the extent of EMG oscillation due to the magnitude of corticomuscular coherence leads to variations of motor function. To test this hypothesis, the present study explored the potential effects of the β-band corticomuscular coupling on ballistic new movement as assessed by reaction time (RT). First, we calculated the coherence between electroencephalogram (EEG) over the sensorimotor cortex and rectified EMG from the tibialis anterior muscle during tonic isometric contraction in 15 healthy subjects. Based on the data, we classified the subjects into two groups; i.e., the subjects showing significant EEG-EMG coherence (COH+, n = 8) or the subjects showing no significant coherence (COH-, n = 7). Next, the subjects performed ballistic contractions in reaction to auditory signals from the preliminary sustained contractions for 100 times. RT was defined as an interval between the signals and the response onset. There was no inter-subject difference in RT between COH+ and COH-. However, when the trials performed by COH+ subjects were divided into two groups depending on whether clear grouped discharge was observed in EMG (GD+) or not (GD-) before reaction, RT was significantly longer in GD+ than in GD- trials. Pooled EEG-EMG coherence was significantly greater in GD+ than in GD- trials. These results indicate that the magnitude of corticomuscular coupling of COH+ subjects fluctuates from moment to moment, and a reaction of new movement is delayed when corticomuscular coupling is greater. We suggest that β-synchrony in the corticospinal system impairs the ability for a rapid modulation of the firing rate of cortical neuron population, and therefore slows reaction of ballistic new movement.

Title: Fractionation of muscle activity in the StartReact paradigm

Authors: *L. R. DEAN, S. N. BAKER
Inst. of Neurosci., Newcastle Univ., Newcastle Upon Tyne, United Kingdom

Abstract: Reaction times (RTs) of movements performed in response to loud, acoustically startling stimuli are around 80ms shorter than those following a quiet cue (Valls-Sole et al. 1995). Such 'StartReact' RTs may be too short for cortical involvement, and could reflect storage of a prepared movement in a sub-cortical structure, and rapid release of this motor programme by the startling sound. The reticular formation (RF) and its descending output via the reticulospinal tract play a well-established role in the acoustic startle reflex. The early phase of StartReact responses could be mediated via the reticulospinal tract, in contrast to a primarily corticospinal pathway underlying typical voluntary reactions.

Axons of the reticulospinal tract make divergent connections to multiple muscles, in contrast to the more focal termination pattern of single corticospinal axons, which each innervate only a small number of motoneuron pools. We hypothesised that muscle activity patterns would be less flexible and more stereotyped in the early part of StartReact responses compared to those following slower onset voluntary reactions.

To test this hypothesis, 5 subjects were asked to carry out 32 different movements in response to a quiet (ca. 80dB) or startling (ca. 115-120dB) acoustic stimulus. Example movements were gripping a variety of objects, pulling against elastic loads, and clicking a mouse button. Surface electromyograms (EMG) were recorded from 16 muscles in the proximal and distal upper limb. The single-trial reaction time was detected as the earliest EMG onset latency, and the mean activity in each muscle measured over the subsequent 50ms. These EMG activities were subjected to principal component analysis, to see how effectively muscle patterns could be represented by a low-dimensional space.

The proportion of the variance explained by successive principal components was not significantly different for short-latency responses to loud cues, and for longer latency responses to quite cues. This suggests that muscle activation patterns were similarly fractionated in the two response types, and are thus likely to be initiated by a descending tract with similar divergence to motoneuron pools. We thus propose that the corticospinal tract plays a key role in both StartReact and more usual voluntary reactions. It remains possible that the reticulospinal tract contributes to reaction time shortening by delivering an unfocussed input, raising the excitability of many motoneuron pools and allowing a rapid fractionated response to subsequent more focal corticospinal input.

Title: A moving motor homunculus? Dynamic representations of intrinsic hand muscles in two arm postures

Authors: *H. VAN DUINEN, C. BROZZOLI, H. H. EHRSSON
Karolinska Institutet, Stockholm, Sweden

Abstract: Background: The human primary motor cortex is somatotopically organized; different body parts are represented in different territories, and single muscles also have their representations. This study examined the assumption that such maps are stable across limb postures.
Methods: We measured corticospinal excitability using transcranial magnetic stimulation (TMS) over a grid of 25 stimulation sites (5x5 cm) centered over the left primary motor cortex (n=13). The corticomotor representation was mapped for two intrinsic hand muscles (first dorsal interosseus, FDI, and abductor digiti minimi, ADM), while the right arm was lying on a table in front of the subjects in two different postures, namely with the right hand at the right side of the body and with the right hand crossing over to the left. Each site was stimulated 8 times in both arm postures. All motor evoked potentials (MEPs) were expressed as a percentage of the maximal compound muscle action potential.
Preliminary results: Overall corticospinal excitability was higher for FDI than for ADM (averaged over all stimulation sites; $p=0.023$). Furthermore, the difference in corticospinal excitability between the two muscles changed between the two arm postures ($p=0.026$). FDI showed greater excitability when the right hand was placed to the left side and ADM greater

excitability with the right hand on the right. These changes occurred without any registered change in the peripheral muscle output. We also observed dynamic changes in the corticomotor maps with the peak response spatially shifting dependent on arm posture. Moreover, the corticospinal excitability in the site of best response for one arm posture was higher than the response at the same stimulation site with the arm in the other posture (FDI: $p<0.037$; ADM: $p<0.014$).
Conclusions: Changes in arm posture induced changes in the general corticospinal excitability recorded from intrinsic hand muscles. Furthermore, changes in arm posture cause changes in the location of the site of best response in the motor cortex. These findings indicate that the proprioceptive information related to arm posture dynamically modulates the representation of intrinsic hand muscles in the motor cortex. This dynamic representation can have important implications for the development of rehabilitation training programs after stroke.

Title: Strength of beta-band corticomuscular coupling is modulated moment-by-moment during low-level prolonged contraction

Authors: *J. USHIYAMA[1,2], M. LIU[1], J. USHIBA[1,3]
[1]Dept. of Rehabil. Med., Keio Univ. Sch. of Med., Tokyo, Japan; [2]Grad. Sch. of Sci. and Technol., [3]Dept. of Biosci. and Informatics, Fac. of Sci. and Technol., Keio Univ., Kanagawa, Japan

Abstract: Oscillatory neural activity of the sensorimotor cortex measured by electroencephalogram (EEG) shows coherence with electromyogram (EMG) activity of contralateral limb muscles within the 15-35-Hz frequency band (beta-band) when performing weak to moderate intensity of isometric voluntary contraction (e.g., Conway et al., 1995; Mima et al., 2000; Ushiyama et al., 2011). Recently, it has been suggested that this corticomuscular coupling is mediated by not only motor pathways, but also somatosensory pathways, and reflects the sonsorimotor integration processes (e.g., Riddle & Baker, 2006; Witham et al., 2011).

The present study was designed to examine whether the strength of the beta-band corticomuscular coupling is constant or fluctuates during low-level prolonged contraction, which does not induce prominent muscle fatigue. Seven healthy young adults (three males and four females, 21-35 years) performed low-level prolonged dorsiflexion at 2.5% of maximal voluntary contraction (MVC) for 60 min. During the task, we recorded EEG over the sensorimotor cortex and surface EMG from the right tibialis anterior muscle. We found that EMG activation patterns changed moment-by-moment during prolonged contraction; i.e., in one times the EMG signals showed prominent grouped discharges within the beta-band, while in other times it showed tonic activation patterns. When we compared EEG-EMG coherence between the period with clear grouped discharge and the one with no grouped discharge, the magnitude of beta-band EEG-EMG coherence was significantly greater in the former period. Additionally, as a result of time-frequency analyses of EEG-EMG coherence, we found that the magnitude of the beta-band EEG-EMG coherence fluctuated randomly. We speculate that by occasionally elevating the corticomuscular coupling during prolonged contraction, the central nervous system may promote a sensorimotor recalibration, providing updated information about the state of the semsorimotor system. In return, the increased oscillation in EMG would impair the stability of motor output in such periods.

Title: Decoding onset and direction of movements using electrocorticographic (ecog) signals in humans

Authors: *A. GUNDUZ[1,2,3], Z. WANG[4], P. BRUNNER[2,3], Q. JI[4], G. SCHALK[2,3,4,5]
[1]Biomed. Engin., Univ. of Florida, Gainesville, FL; [2]Wadsworth Ctr., Albany, NY; [3]Albany Med. Col., Albany, NY; [4]Rensselaer Polytechnic Inst., Troy, NY; [5]State Univ. of New York, Albany, NY

Abstract: Communication of intent usually requires motor function. This requirement can be limiting when a person is engaged in a task, or prohibitive for some people suffering from neuromuscular disorders. Determining a person's intent from brain signals rather than from muscles would have important applications in clinical or other domains. For example, detection of the onset and direction of intended movements may provide the basis for restoration of simple grasping function in people with chronic stroke, or could be used to optimize a user's interaction with the surrounding environment. In this study, we investigate whether electrocorticographic (ECoG) signals, collected from five human subjects engaged in an 8-target center-out task, hold information about the onset and direction of hand movements. In each trial, subjects were presented with a target, but had to wait for a cursor to appear (i.e., a “go” cue) before they could hit the target using a joystick. We characterized the neural mechanisms involved in intention and movement by determining ECoG amplitude changes in mu (8-12 Hz), beta (18-26 Hz), high gamma (70-170 Hz) bands, and in the moving average of the raw signals, also known as the local motor potential (LMP).
For the detection of movement onset, we used a support vector machine (SVM) that determines from 1 s of accumulated ECoG activity the probability that the subject would initiate a hand movement in the next time step. We then used a novel implementation of a time-varying dynamic Bayesian network (TVDBN), which was designed to take advantage of the spatio-temporal dynamics of ECoG features, to determine the direction of the intended movement using ECoG signals prior to the movement. Finally, we simulated a targeting application in which brain signals prior to the movement are combined with the actual movement signals. In this simulation, the time-to-target reduced by up to 150 ms when we use the directional information captured in ECoG signals. Overall, our results contribute to our understanding of the neural representation of intended movements and suggest that integrating information from brain signals and motor execution may eventually lead to systems that can improve a user's performance.

Abstract: The capacity to endogenously and intentionally inhibit actions that we have planned is crucial in human behaviour, but the way in which such a mechanism operates and what influences contribute to a decision to act or not act remain largely unexplored. Here, we use human EEG to examine the readiness potential (RP) during a continuous stream of actions, and to explore preparatory activity during omissions of actions in the sequence. We compare activity for omissions made based on a pre-specified rule, to omissions freely decided on by the participant. We find that RP amplitude is reduced for actions that immediately precede a voluntary omission, suggesting that the motor system is already primed to make an omission before it occurs. This is not found for rule-based omissions. When comparing the omissions themselves, there is also a divergence in preparatory activity slopes into opposite polarities, with rule-based omissions showing a pattern similar to a typical RP but voluntary omissions showing an opposite pattern, seemingly reflecting suppression of weak motor activity. The results suggest that spontaneously fluctuating activity in the motor system could bias voluntary action selection when options are closely competing and a decision must be made between them.

Title: Can anodal tDCS stimulation over V1 alter visuomotor behavior?

Authors: *H. J. BLOCK[1,2], N. D. PASRICHA[1], P. CELNIK[1,2,3]
[1]Physcial Med. & Rehabil., Johns Hopkins Sch. of Med., BALTIMORE, MD; [2]Neurosci., [3]Neurol., Johns Hopkins Sch. of Med., Baltimore, MD

Abstract: Electrical stimulation of primary sensory cortex can induce changes in sensory perception. For example, anodal transcranial direct current stimulation (tDCS), a non-invasive technique for modulating cortical excitability via GABA and NMDA receptor activity, applied over the primary visual cortex (V1) results in changes in contrast sensitivity (Spiegel et al 2012, PLoS One). However, it is unclear to what degree tDCS-induced changes in primary visual cortex can affect sensorimotor behavior. If tDCS of primary sensory cortex can affect motor behavior and multisensory processing in addition to unisensory perception, it may be a potential tool in rehabilitation of individuals with sensory deficits such as low vision or proprioceptive loss. Here we address this question in healthy young adults, asking if anodal tDCS over V1 can decrease subject's variability in pointing to visual targets. In addition, we assess whether this intervention affects visuoproprioceptive weighting (how much the brain relies on vision vs. proprioception when estimating the hand's position) or realignment (how much the brain adjusts vision vs. proprioception when a visuoproprioceptive misalignment is experimentally introduced). Right-handed subjects sat at a reflected rear-projection setup with no vision of either hand. The tDCS anode was placed over the occipital pole and the cathode on the subject's right cheek. The behavioral task involved moving the right index finger from a start position to a series of visual (V), proprioceptive/left finger (P), or combined (VP) targets. After a baseline reaching period consisting of alternating V, P, and VP targets, the V component began to gradually shift away from the left finger's position such that by the end of the Adaptation block, subjects experienced a 7-cm misalignment between visual and proprioceptive information about their target finger's position on VP trials. 2mA of current was turned on halfway through the baseline period and remained on until the end of Adaptation (Real, N=10) or was turned off after 30s (Sham, N=14). Subjects who received real tDCS of V1 decreased their pointing variability on V targets relative to sham tDCS subjects ($p=0.020$), but pointing variability to P targets was unaffected. Visuoproprioceptive weighting and realignment also appear unaffected by V1 tDCS. These results suggest that anodal tDCS over V1 can improve movement precision during visuomotor behavior.

Title: Movement observation modulates interhemispheric inhibition: An ipsilateral silent period study.

Authors: C. PAPAXANTHIS[1], N. GUEUGNEAU[1], T. POZZO[1,2], M. BOVE[3], *L. AVANZINO[3]
[1]INSERM, U 1093, Cognition, Action, et Plasticité Sensorimotrice, Univ. de Bougogne, Dijon, France; [2]Inst. Universitaire de France, Dijon, France; [3]Dept. of Exptl. Med., Univ. of Genoa, Genoa, Italy

Abstract: While it has been shown that voluntary control of action involves fine neural interactions between both motor cortices, the question of such an interhemispheric communication during covert actions has not been fully studied (Giovannelli et al., 2009; Carson and Ruddy, 2012). Particularly, the implication of the transcallosal inhibitory circuits during the perception of other's movement is still unknown. Here, we wanted to know if movement observation could specifically affects interhemispheric inhibition. Thus, we quantified the ipsilateral silent period (ISP) in the left opponens pollicis (OP) in healthy subjects. The ISP is a short attenuation of an ongoing voluntary electromyographic (EMG) activity in a specific muscle, which is induced by focal transcranial magnetic stimulation (TMS) of the ipsilateral primary motor cortex. This paradigm is well suited to investigate interhemispheric inhibitory control of voluntary cortical motor output. We evaluated the ISP in the left OP from 17 right-handed adults while they were actively observing fine hand movements performed by an experimentalist in front of them (i.e. grasping and tapping movements executed with the right hand). The size of the ISP was assessed during different movement conditions: at rest, during the closing phase of grasping and tapping movements, and during the opening phase of the same motor tasks. Our data showed a clear increase of the ISP during movement observation (on average, 22.7 ms for grasping and 24.3 ms for tapping) compared to the rest (on average, 16.3 ms) condition. More interestingly, the increase of the ISP was specifically tuned to the kinematics of the observed finger movements (on average, 17.3 ms and 19 ms for the grasping and tapping opening phase, respectively). Although movement perception has been widely shown to facilitate the central motor circuits, here we bring novel data that point out the fact that movement perception has significantly influence on inhibitory interhemispheric circuits. Interestingly, this modulation seems to be tuned to the kinematic pattern of the observed movement. Our study therefore deepens the concept of mirroring, or motor resonance, and indicates that transcallosal structures that mediates inhibitory motor signals are significantly implicated during movement observation.

Title: Comparing the electrophysiology and decoding power associated with each hemisphere during direction specific movements using ECoG in humans

Authors: *M. SHARMA[1], C. M. GAONA[1], N. SZRAMA[1], J. D. BRESHEARS[4], J. ROLAND[2], Z. FREUDENBURG[3], K. Q. WEINBERGER[3], E. C. LEUTHARDT[2]

Abstract: Numerous studies have shown the efficacy of electrocorticographic (ECoG) signal in both understanding the movement related electrophysiology and kinematic decoding. Although the importance of activity contralateral to the moving limb is extensively studied and well understood, the understanding behind the ipsilateral activity is still not well established. Many imaging studies have suggested that ipsilateral M1 cortical activity is a result of transcallosal inhibition to prevent the unwanted co-activation of the other limb. More recent evidence, however, suggests that ipsilateral cortical activity represents a unique physiologic process and is more associated with motor planning than its execution. Researchers have shown the existence of directional tuning on the hemisphere ipsilateral to the moving limb, which indicates that ipsilateral activity is, to some degree, analogous to the contralateral activity. In this study, we hypothesize that ipsilateral activity encodes kinematic information, which can be used to decode movement direction. We also provide a direct comparison to information decoded from contralateral hemisphere.
ECoG data was collected from five human subjects while they performed a center out joystick task with their hand either ipsilateral or contralateral to the grid. Both datasets were separately analyzed for power changes (features) during the planning, movement and reward phases of the task. Using well-established machine learning techniques, these features were used to decode the direction of movement. Our findings show that although in comparison to contralateral, ipsilateral decoding accuracies are lower, yet significantly above chance. It was also found that different features contribute differently depending on the hemisphere. Specifically, whereas contralateral accuracies peaked when primary motor areas were used for decoding; ipsilateral accuracies peaked when the features used were from pre-motor areas, suggesting its involvement

in planning rather than execution of movement.
The results of this study suggest that cortical activations during ipsilateral motor task contain more complex activation patterns, which can be used to decode kinematic information. Although the amount of information decoded from ipsilateral cortex is lower than contralateral, it is still significant. These results further support an understanding of the active role that ipsilateral cortex plays during motor activities. This also extends the notion that ipsilateral cortical activity could provide important information that can be utilized for control of Brain Computer Interfaces.

Title: Whole-cell recordings from mouse forelimb motor cortex neurons during targeted reaching.

Authors: *B. C. VOIGT, J. F. A. POULET
NeuroCure, Max Delbrück Ctr. For Mol. Med., Berlin, Germany

Abstract: Primary motor cortex (M1) controls voluntary movement. While a number of studies have documented extracellular recordings during motor tasks, there is very little data available on the synaptic activity underlying motor processing in M1. Here we present whole-cell recordings from forelimb primary motor cortex (fM1) in mice trained to perform a forelimb reach and touch task. To locate fM1 we performed electrical microstimulation in anaesthetised mice and, in good agreement with previous studies, found fM1 centered 0.3 mm anterior and 1.6 mm lateral to bregma. Up to 6 head-restrained mice were trained in parallel within 6-10 days to reach and touch a sensor. Pharmacological inactivation experiments with cortical microinjections of the GABA-A receptor agonist muscimol confirmed that the behaviour was dependent on fM1 activity. Whole-cell recordings from fM1 in awake, behaving mice revealed strong state-dependent changes in subthreshold activity. When mice were sitting still, large amplitude, slow oscillations were observed in fM1 neurons. During reaching, by contrast, the membrane potential was depolarised and smaller amplitude, higher frequency events occurred. This confirms that state-dependent changes in cortical activity are present in alert, trained mice performing

cortically dependent behaviour. Here we have developed an M1 dependent motor task that will allow investigations into the cellular, synaptic and network mechanisms underlying cortical motor control.

Title: Motor cortical representation of human auricular muscles: A robot-assisted and image-guided TMS mapping study

Authors: *J. MEINCKE, M. HEWITT, D. LIEBETANZ
Dept. of Clin. Neurophysiol., Univ. Med. Ctr. Göttingen, Goettingen, Germany

Abstract: In non-human species the auricular muscles play an important role during locating of acoustical sources. Besides neuroanatomical track tracing studies in primates, only sparse information exists concerning the neuroanatomy or function of the human auricular muscles, which are usually considered as rudimentary. To reveal the neuroanatomical structures involved in the function of these muscles, we aimed at determining a possible motor cortical representation of the auricular muscles in humans.
We performed a transcranial magnetic stimulation (TMS) mapping procedure on 8 healthy subjects (6 male; mean age 26,5 ± 5,0 years) using a novel robot-assisted and image-guided technology. A robotic arm (Adept Viper s850), linked to individual MRI data, ensured an exact positioning of the coil over the grid points with respect to the 6 degrees of freedom of the coil. For neuroanatomical mapping 12 TMS pulses were delivered over each point of a 7 x 7 cm grid with 1 cm spacing in a random sequence. EMG was simultaneously recorded from the contralateral posterior auricular muscle (PAM) using fine wire electrodes. Individual centers of gravity (COGs) were calculated and a TMS recruitment curve was recorded at this position.
In all subjects TMS over the primary motor cortex induced MEPs in the pre-innervated PAM with a mean onset latency of 9,2 ms (SD: 0,9). The hotspot was located on the precentral gyrus lateral to the first dorsal interosseus (FDI) hotspot, which was defined in a control experiment. The inter-COG distance between both muscles was 23,8 mm (SD: 5,1). In addition, MEP amplitudes in PAM depended on the intensity of stimulator output.
Our mapping results identify for the first time a specific motor cortical representation area of a

human auricular muscle which is located in short distance to the hand muscle area. The involvement of the primary motor cortex in the connectivity of auricular muscles may represent a neuroanatomical correlate of voluntary auricular muscle activation. Our results also point to a specific function of these muscles in humans, which still has to be

Positions of the centers of gravity (COGs) of the first dorsal interosseus muscle (FDI) and posterior auricular muscle (PAM) as determined by TMS mapping in 8 subjects and registered to the MNI152 T1 template. All COGs of PAM and FDI are located on the precentral gyrus.

Title: Variability of cortico-spinal excitability tracks the preparatory state of human motor cortex

Authors: *M. C. KLEIN-FLÜGGE[1], D. NOBBS[1], J. B. PITCHER[2], S. BESTMANN[1]
[1]Sobell Department, UCL, London, United Kingdom; [2]Sch. of Paediatrics and Reproductive Health, Res. Ctr. for the Early Origins of Hlth. and Disease, Univ. of Adelaide, Adelaide, Australia

Abstract: Introduction: Task-evoked trial-to-trial variability is a ubiquitous property of neural responses, yet its functional role remains largely unclear. Recent work in non-human primates shows that the temporal structure of across-trial neural variability in several brain regions is task-related. For example, neural variability in pre-motor cortex tracks motor preparation, with increasingly consistent firing rates and thus a decline in variability prior to movement onset (Churchland et al., JNeurosci, 2006). However, whether non-invasive read-outs of the variability of population activity available from humans can also track the preparation of actions remains unknown.
Methods: We tested this by measuring cortico-spinal excitability (CSE) at different times during action preparation, using single-pulse transcranial magnetic stimulation (TMS) to the hand representation of human primary motor cortex (M1). Specifically, we sought to examine whether changes in variability prior to a movement differ a) between chosen and unchosen actions and b) processes involved in decisions-for-actions versus instructed action selection. First, we established the basic properties of intrinsic CSE variability at rest (n=46) which revealed a logarithmic relationship between CSE and variability. During the task (n=15), responses (left/right button press) were then either directly instructed (no-choice), or resulted from a value-decision (choice).
Results: Compared to rest, CSE variability during task performance was significantly increased throughout the trial. Notably, there was a further task-related decline in variability from about 230ms prior to movement onset in the responding hand which was more pronounced on fast compared to slow response trials, consistent with data in non-human primates. Critically, this effect occurred over and above that trivially expected based on the concurrent rise in CSE during motor preparation. Finally, variability showed a decrease for the unselected hand on choice trials only, possibly reflecting choice-specific suppression of unselected actions.
Conclusion: Measures of human CSE variability thus track the preparatory state of motor cortex, analogous to changes in firing rate variability during action preparation in monkeys that reflect the optimization of preparatory activity. This provides novel ways in humans to study the dynamics of action preparation but also more complex processes such as choice-to-action transformations.

Title: Variability of corticomotor excitability as an indicator of imagery ability

Authors: F. LEBON[1], C. STINEAR[2], W. BYBLOW[2], *C. PAPAXANTHIS[1]
[1]UFR STAPS, Univ. de Bourgogne, Dijon, France; [2]Univ. of Auckland, Auckland, Ctr. for Brain Res., Auckland, New Zealand

Abstract: Motor imagery (MI) is the mental representation of an action without any concomitant motor output. Corticomotor excitability, assessed by motor evoked potentials (MEPs) from transcranial magnetic stimulation (TMS) of primary motor cortex is facilitated during MI and correlated to imagery ability (Lebon et al., 2012). In the present research, we examined the relationship between variability of MEPs and MI ability. Nineteen healthy adults (10 females; mean age = 26 ± 10) were assessed using the Motor Imagery Index (Collet et al., 2011) which is based on 6 sub-indicators: 1) Level of skin conductance (SC) , 2) Ohmic perturbation duration of skin conductance (OPD), 3) Respiratory sinus arrhythmia (RSA), 4) Mental chronometry (MC), 5) Self-estimation of imagery quality (SE), and 6) the revised version of movement imagery questionnaire (MIQ-R). Single-pulse TMS was delivered to the left primary motor cortex to elicit MEPs in the right opponens pollicis, when participants imagined a thumb tapping movement with their right hand. The intensity of TMS pulse was set to elicit 1 mV MEP amplitude at rest. The coefficient of variation (CV) of MEP amplitude from 12 MEPS collected during MI was determined. We performed a Least Squares Linear Regression, with CV as dependent variables (n = 19) and the 6 indicators of imagery quality as independent variables. The average CV was 0.46 during MI, and the linear regression was statistically significant ($R2 = 0.662$, $F = 3.915$, $P = 0.021$) for predictor variables SC, OPD, SE and MIQ-R . The variability of MEP amplitudes during MI was inversely correlated to imagery ability: the smaller the variability, the better the imager. In addition to the facilitation of corticomotor excitability during MI, the variability of responses provides relevant information to assess imagery ability.

Title: Influence of an acute bout of aerobic exercise on cortical contributions to motor planning and execution

Authors: *J. S. THACKER, W. R. STAINES
Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Increasing evidence supports the use of physical activity for modifying brain activity and overall neurological health[1]. Specifically, aerobic exercise appears to improve cognitive efficacy with regards to decisional oddball tasks shown through the P300, whose amplitude and latency is augmented[2]. Furthermore, the effects of an acute bout of aerobic exercise on cardiovascular function are well established and are sustained following exercise cessation. Based on these findings, we proposed that (1) an acute bout of exercise may modulate movement-related cortical excitability within motor areas and (2) that transient effects would be sustained as long as heart rate (HR) remained elevated. Subjects (n=11) were placed in a soundproof booth and instructed to perform a self-paced unimanual ballistic wrist extension every 3-6 seconds of the right wrist while holding a moveable handle. The motion involved a brisk contraction followed by relaxation and positional reset, collected continuously for approximately 8 minutes. Electroencephalography was used to measure movement-related cortical activity using the Bereitschaftspotential (BP) time-locked to onset of muscle activity associated with movement. Following baseline measures, subjects performed 20 minutes of aerobic exercise at a moderate intensity (70% of age-predicted maximum heart rate) on a recumbent cycle ergometer. After the cessation of exercise, BP measures were recorded at two timepoints: immediately post-exercise (Post) and following a return to baseline HR (Post[Rest]), which was, on average, 45 minutes after the cessation of exercise. Movement characteristics were measured using both a potentiometer imbedded in the handle and electromyography (EMG) over the extensor carpi radialis muscle. The BP was separated into two components: the early, motor preparatory (BP1) and late, motor execution (BP2) phases. BP1 onset appears to present earlier and with larger amplitude, trending in Post and becoming significant ($p<0.05$) in the Post(Rest) condition compared to pre-exercise baseline measures. However, peak BP2 amplitudes, latency and slope did not reveal any significant differences in Post and Post(Rest) conditions for any electrode sites. In addition, no significant differences were found in the EMG profiles between all time conditions. These data suggest that motor preparation is susceptible to modulation by aerobic exercise. In addition, this affect seems more prominent even after other physiological markers such as HR have returned to pre-exercise baseline measures.

Title: Interaction between selective attention and response selection during motor decision making

Authors: *P.-A. KLEIN[1,2], Q. FAVRE[2], A. MOURAUX[2], S. NOZARADAN[2], A. ZENON[2], J. DUQUE[2]
[1]Univ. Catholique De Louvain, Brussels, Belgium; [2]Inst. of Neurosci., Univ. catholique de Louvain, Brussels, Belgium

Abstract: On most occasions, multiple stimuli in the environment call for attention and action. We continuously have to attend to and act towards stimuli which are the most compatible with our goals, while refraining from selecting less relevant, yet possibly appealing, options. As such, decision making involves at least two major interrelated processes. The first one, called "selective attention", biases competitive interactions between sensory stimuli by favoring processing of information that is relevant to specific goals while ignoring irrelevant stimuli. The second process, "response selection", is associated with the accumulation of activity in competing response representations so as to ensure that only motor activity related to the most beneficial action reaches threshold and is selected.
Here, we used electroencephalography to characterize the interactions between selective attention and response selection. Participants performed a version of the Flanker task in which they were asked to indicate by a left or right button-press the orientation of a briefly presented left- or right-facing central arrow, flanked by a set of two distractor arrows on each side which either pointed in the same (congruent trials) or in opposite -conflicting- directions (incongruent trials). The proportion of congruent and incongruent trials was manipulated to produce two different conditions. In one of them, most trials were incongruent (80%) and thus subjects expected to face conflict (high conflict blocks, HCBs); in the "low conflict blocks" (LCBs), most trials were congruent (80%). Selective attention and response selection processes were assessed in each trial of the two block types by recording steady-state visual evoked potentials (SSVEP, central and distractor arrows flicked at different frequencies) and lateralized readiness potentials (LRPs over motor areas), respectively.
Behavioural and EEG data were collected on a preliminary set of 6 participants. As expected,

response times and error rates were larger in incongruent compared to congruent trials. However, this difference was attenuated in the HCBs compared to the LCBs, probably because in HCBs, control mechanisms were recruited to help sharpen selective attention and response selection. Our preliminary EEG data are consistent with this hypothesis. SSVEP recordings indicate a more selective processing of the central arrow (compared to distractors) in the HCBs than the LCBs. This effect was associated with larger and earlier LRPs in incongruent trials of the HCBs than LCBs. More subjects are required to establish precisely the relationship between SSVEPs and LRPs measures, with respect to behavior.

Title: Modulation on motor inhibition control caused by transcranial magnetic stimulation

Authors: *O. HIWAKI, N. ISHIMARU, H. FUKUDA
Grad. Sch. of Information Sciences, Hiroshima City Univ., Hiroshima, Japan

Abstract: The flexible voluntary motor control is achieved with the plan prior to the movement and on-going adjustment. The function of the motor cortex for dynamic control of the finger motor inhibition has not yet been well understood. In the present study, we investigated the property of the voluntary finger force control involving inhibitory alteration triggered by the stop signal. The transcranial magnetic stimulation (TMS) of the motor cortex was applied for dynamic interference with on-going motor control processed in the motor cortex. The series of the go-stop task of the index finger movement, which consisted of TMS trials and sham TMS trials, was conducted. A clock whose hand completed a full rotation for four seconds was indicated on the PC monitor. The subject was instructed to start pushing a force sensor with an index finger at the moment the clock hand passed the line at three o'clock position. The subject controlled finger force increasing toward 2 N with watching the force indicator displayed on the monitor after the movement initiation. The subject was also asked to abandon the finger push movement when the stop signal with a red LED was indicated at the start time of the movement, that is, the time the clock hand passed the line at three o'clock position. In the trials with TMS, the single pulse TMS of the motor cortex was conducted at -100 ms, -50 ms, 0 ms, 50 ms, 100

ms, 150 ms, 200 ms and 250 ms after the start time of the movement. In the sham TMS trials, the TMS coil located over the scalp made clicking sound without stimulation of the motor cortex at the same timings as the TMS trials. As a result, the TMS prior to the stop signal inhibited the voluntary finger movement, whereas the TMS conducted at 100 ms and 150 ms after the stop signal enhanced the voluntary finger movement. The result suggests that the TMS of the motor cortex modulates the motor inhibition control of the voluntary finger movement. The timing of the TMS is important for inhibition or enhancement effect of TMS on the inhibitory motor process.

Title: The role of attention on early somatosensory processing in frontal areas involved in movement planning and preparation

Authors: *M. J. N. BROWN, W. R. STAINES
Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Short-latency somatosensory evoked potential (SEPs) in parietal and frontal areas represent the earliest input of ascending somatosensory information into cortical areas. Studies on parietal SEPs have found that increasing attention (i.e. counting peripheral stimulations) may enhance the amplitude of parietal SEPs possibly as early as the P27 component. The frontal N30, a SEP component maximal over frontocentral sites, is thought to represent early somatosensory input to non-primary motor areas for planning and preparation of movement. Although movement (or mental simulation) can modulate the frontal N30, it is unclear how early somatosensory input is influenced by attention when such afferent information is needed for stimulus detection or sensory-guided movement. The first study recorded SEPs (i.e. N30) using a 64-channel EEG cap in 10 healthy young adults (22-38yrs) time-locked to peripheral median nerve (MN) stimulation to the left or right wrist. Attention was modulated by having participants silently count the number of infrequent high and low targets embedded with frequent non-targets to either the left (AttL) or right (AttR) index finger provided by vibrotactile stimulation. In addition, control conditions included participants silently counting backwards by 7 (Count) or

sitting quietly (Rest) during MN and index finger stimulations. It was hypothesized that unlike parietal components, attention would not modulate the frontal N30 during tactile detection since this afferent information is irrelevant for planning a movement. Statistical analyses revealed no significant effects of attention on the peak amplitude of the frontal N30 or on the peak-to-peak amplitude of P20-N30 complex ($p>0.05$). As expected, these results suggest that attentional modulations do not influence early somatosensory input to non-primary motor areas during detection of tactile stimuli. Consequently, this supports that the movement afferents to frontal non-primary motor areas are not influenced by a global increase in activity in the attentional network. The second study used a similar experimental design to measure whether modulations of the frontal N30 are observed when participant's direct attention to tactile stimulations that are required to prepare and execute a movement (i.e. finger tapping sequence). Finger tapping sequences were matched to the infrequent low or high targets provided by vibrotactile stimulation to the index fingers. Results will be discussed on whether combining attention of tactile stimuli relevant for planning a movement modulates early somatosensory input to frontal areas.

Title: SSVEP based BCI system as general control interface for computer programs using a new overlay technique

Authors: *C. KAPELLER[1], C. HINTERMÜLLER[1], M. ABU-ALQUMSAN[2], B. GROßWINDHAGER[1], R. PRÜCKL[1], A. PEER[2], B. ALLISON[3], C. GUGER[1]
[1]Guger Technologies OG, Schiedlberg, Austria; [2]Tech. Univ. of Munich, Munich, Germany; [3]Univ. of California at San Diego, La Jolla, CA

Abstract: A brain-computer-interface (BCI) allows the user to control a device or software with brain activity. A BCI system can help disabled users communicate with their environment. Many BCIs rely on visual stimuli with constant stimulation cycles that elicit steady-state visual evoked potential (SSVEP) activity in the electroencephalogram (EEG). The SSVEP response can be generated with (i) a computer screen flashing with a constant frequency (f-VEP) or with (ii)

pseudo-random stimulation frequencies of a computer screen (c-VEP). This study compared these BCI methods in a new type of SSVEP BCI that used streaming video to help control a robotic device through tele-presence (Figure 1). The BCI controls were overlaid on a video image that showed a robot performing tasks in a remote environment. The designed stimulation module allows the integration of BCI controls in any OpenGL based graphics application. 11 healthy subjects used the BCI to drive a robot along a certain path as quickly and accurately as possible. The subjects used 4 BCI controls (forward, left, right, backward) to steer the robot based only on the video image of the robot. Results showed that the new video BCI overlay method was very robust and that the simultaneous video did not impair performance. The maximum online accuracy was 91.36 % (i), and 98.18 % (ii). The average time to complete the tasks was 573.43 s (i), and 222.57 s (ii). Subjects needed 93.29 s to complete the task with keyboard. Interestingly, all of the subjects achieved accuracy above 90 % in the c-VEP configuration, while three subjects were below 90 % using the f-VEP configuration. Therefore the c-VEP based BCI seems to be the fastest, most accurate, and most universal BCI in this study. Also, all of the subjects were comfortable with the video BCI overlay implementation that combined video images and BCI controls on one screen, which should increase usability and presence. This is especially noteworthy because both the control and feedback were continuous and not discrete, which is more realistic in many field settings but might have entailed greater distraction or confusion.

Title: SSVEPs generated by unattended flickering fields can be used to predict the locus of covert spatial attention

Authors: *R. A. COLEMAN[1,2,3], A. LI[2], M. D'ZMURA[2]
[1]Cognitive Sci., Univ. of California, Irvine, Irvine, CA; [2]Univ. of California, Irvine, Dept. of Cognitive Sci., Irvine, CA; [3]Univ. of California, Irvine, Dept. of Statistics, Irvine, CA

Abstract: Users of current SSVEP BCIs attend to one of several discrete flickering fields to issue a command. We are studying the use of SSVEPs generated by peripheral, unattended, flickering fields. The user freely shifts covert visual attention throughout their visual field. SSVEP amplitudes are used to determine where they pay attention.
We performed an EEG experiment in which subjects were prompted to shift covert visual attention to locations along a horizontal axis while maintaining central fixation. On each trial, subjects attended to a location marked by a letter and used a keyboard to indicate letter identity. During the 2.5-sec trials, subfields at far left and at far right of the display provided contrast reversing flicker at different frequencies. 600 trials were collected per session, for eight sessions per subject, for eight subjects. Trials with incorrect key press responses were excluded from further analysis of EEG data, resulting in a mean of 4566 trials per subject.
EEG data were collected on 64-channel, ANT-NEURO ® EEG systems. Preprocessing generated both 1) autoregressive spectra and 2) canonical correlation analysis filter responses at fundamentals and relevant harmonics of each flicker. These features were used in preliminary analysis to classify trials according to whether attention was directed to the left or to the right of the central fixation point. Probabilistic linear discriminant analysis was conducted within subjects, across sessions, and with leave-one-out cross-validation. Classification resulted in a mean prediction rate of 61% across subjects with best and worst classification rates of 73% and 52%, respectively.
These results show that peripheral, unattended, flicker-induced SSVEPs can be used to predict the hemi-field in which the viewer is attending covertly. This motivates current work on whether the position of horizontal attention can be predicted continuously from SSVEPs. Such a BCI could be used alone or with other BCI methods to advance the state-of-the-art.

Title: Application of hemodynamic prefrontal cortex desirability signals as reinforcers in machine learning

Authors: M. M. DISTASIO[1], *J. T. FRANCIS[2]
[1]Physiol., SUNY Downstate Med. Ctr., BROOKLYN, NY; [2]SUNY Downstate Med. Cent, BROOKLYN, NY

Abstract: Decision-making ability in the frontal lobe (among other brain structures) relies on the assignment of value to states of the organism and its environment. Then higher valued states can be pursued and lower valued (or negative) states avoided. The same principle forms the basis for computational reinforcement learning controllers, which have been fruitfully applied both as models of value estimation in the brain, and as artificial controllers in their own right. This work shows how state desirability signals decoded from frontal lobe hemodynamics, as measured with near-infrared spectroscopy (NIRS), can be applied as reinforcers to an adaptable artificial learning agent in order to guide its acquisition of skills. A set of experiments carried out on an alert macaque demonstrate that both oxy- and deoxyhemoglobin concentrations in the frontal lobe show differences in response to both primarily and secondarily desirable (versus undesirable) stimuli. This difference allows a NIRS signal classifier to serve successfully as a reinforcer for an adaptive controller performing a virtual tool-retrieval task. The agent's adaptability allows its performance to exceed the limits of the NIRS classifier decoding accuracy. We also show that decoding state desirabilities is more accurate when using relative concentrations of both oxyhemoglobin and deoxyhemoglobin, rather than either species alone. This suggests that studies of value-related brain function that infer patterns of neural activity based solely on deoxyhemoglobin concentration (as in fMRI) may yet be incomplete. This work is part of a continuing investigation into the use of reinforcement learning agents as controllers in brain-machine interfaces.

Title: Relationship between P300 latency and accuracy rate of auditory brain-computer interface

Authors: *N. YAMAWAKI, E. KATAYAMA, T. HAYASHI, S. SEKI
Electronic Syst & Info, Kinki Univ., Wakayama, Japan

Abstract: Patients who have difficulty moving their muscles freely due to amyotrophic lateral sclerosis (ALS) require support for various situations that occur in everyday life. Brain-computer interface (BCI) systems using motor imagery or event-related potential provide a means of communication for the patients. However, in later stages of ALS patients lose all voluntary muscular control, including voluntary control of gaze. Since the auditory BCI is suitable for the patients, we have developed a BCI based on auditory stimulation for the communication. P300 event-related potential for three-stimulus oddball paradigm (two target stimuli and one frequent stimulus (pink noise)) was used in the BCI. The frequency of one of two target stimuli was fixed to 3000 Hz, and the other frequency was changed from 300 Hz to 1000 Hz at interval of 100 Hz. Subjects were required to attend to a designated target and ignore the other target and the pink noises. Ten tasks were performed for each target frequency set, such as 3000 Hz and 500 Hz. The EEG signals recorded from Cz (sampling rate 500Hz) of international 10-20 system were used for the BCI. Twenty EEG signals for 512 ms in response to the target stimuli were added and the mean value of the added EEG (ERPs) was low-pass filtered at 4 Hz. The peak-to-peak values of the P300 amplitude for two target stimuli were compared and the stimulus observed larger peak-to-peak value was estimated as the attended target. As a result, the optimum frequency combination was a set of 3000Hz and 500Hz, and an average accuracy rate of 90% (subject A: 90%, B: 90%) was achieved. The P300 latency of low accuracy rate at another target frequency set shows a tendency of decrease.

Title: The contribution of methodological variability to multi-day use of passive brain-computer interfaces

Authors: *J. R. ESTEPP, J. C. CHRISTENSEN
Air Force Res. Lab., WPAFB, OH

Abstract: The application of brain-computer interface (BCI) technology to healthy users is a promising avenue for enriching human-machine interaction. Passive BCI, which can be described as a paradigm of nonvolitional control derived from physiological and behavioral indices, may be especially useful in adapting systems to a user's moment-to-moment cognitive state. Recent work in this area has shown that passive BCI systems suffer from performance degradation over time, which is likely in part due to the underlying machine learning algorithm's inability to generalize to the nonstationary dynamics of a user. This can be ameliorated, to some extent, by the use of learning sets spanning long time courses. However, understanding the sources of variability that influence nonstationarity may lead to improved passive BCI system performance. In an effort to begin to understand what these sources may be, we investigated the most basic potential source of variability, removal and replacement of electrodes used for electrophysiological measurement, and its contribution to machine learning accuracy over the span of several hours. Two groups of participants (ten in each group) completed two blocks of two trials each of the Multi-Attribute Task Battery; task workload was the between-trial manipulation in each block. The blocks were explicitly separated by one hour. In the first group (the control group) the electrodes (vertical and horizontal electrooculography, electrocardiography and five channels of electroencephalography) used in the montage were left in place between blocks. In the second group (the test group) the electrodes were removed at the end of the first block and replaced prior to the start of the second block. The NASA Task Load Index (TLX) was used to assess the participant's subjective workload and electrode impedance was measured before and after each block. Accuracy of an artificial neural network (ANN) learning algorithm, with the learning set derived from the first block, was assessed using nested k-fold cross validation with test sets from both the first (within) and second (between) blocks. Results showed no significant differences in task performance, subjective workload or electrode impedance between groups or blocks. There was not a significant difference in test set accuracy between groups, although within-block accuracy was significantly higher than between-block accuracy. These results suggest that methodological variability, in the form of removal and replacement of electrodes, is not likely a contributor to the decline of the machine learning algorithm's accuracy over time, which was observed in this study as well as others prior.

Title: A new single-trial-EEG-based BCI using silent speech tasks

Authors: *T. YAMAZAKI[1], K. YAMAMOTO[2], K.-I. KAMIJO[3], T. YAMANOI[4]
[1]Kyushu Inst. of Technol., Fukuoka, Japan; [2]Biosci. and Bioinformatics, KIT, Iizuka, Japan; [3]NEC, Tokyo, Japan; [4]Hokkai Gakuen Univ., Sapporo, Japan

Abstract: We have proposed a new single-trial-EEG-based BCI using silent speech tasks. The framework consists of two phases. In the first phase (learning phase), single-trial EEGs and speech signals were recorded during overtly spoken janken tasks. The learning phase specifies a Kalman filter using both spectrograms of the speech signals and independent components (ICs) of the EEGs recorded during the actual janken task. The decoding phase predicts spectrograms for the silent janken by the Kalman filter with the EEGs recorded during the silent task. The present results demonstrated that when using the Kalman filter with the ICs whose dipole solutions were localized to the primary motor cortex, the premotor cortex and/or the Broca's area, covertly spoken vowels for "rock" and "paper" were all correctly recognized for ten subjects.

Title: Decoding gait kinematics from scalp EEG of stroke patients: Preliminary comparison of Wiener and Kalman decoders.

Authors: *K. NATHAN[1], L. FORRESTER[2,3], R. GOODMAN[3], J. L. CONTRERAS-VIDAL[4]
[1]Univ. of Maryland, College Park, MD; [2]Dept. of Physical Therapy & Rehabil. Sci., Univ. of Maryland Sch. of Med., Baltimore, MD; [3]Veteran Affairs Med. Ctr., Baltimore, MD; [4]Lab. for Noninvasive Brain-Machine Interface Systems, Univ. of Houston, Houston, TX

Abstract: Our group has recently shown the feasibility of decoding the kinematic parameters of controlled human locomotion from the lower frequency range of electroencephalographic (EEG) signals during a precision walking task (J Neurophysiol 2011; IEEE TNSRE 2012). Here, we turn our attention to stroke survivors who have had lesions resulting in chronic hemiparetic gait. In an identical experimental set-up based on our prior studies, we recorded the EEG of stroke recovery patients during rest, and normal and precision treadmill walking tasks while tracking bilaterally the kinematics of the hip, knee, and ankle. In offline analysis, we reduced the dimensionality of EEG channels and time lags with principal component analysis, and then passed the reduced data through a Wiener Filter and an unscented Kalman filter to predict estimates of the kinematic parameters. Here, we report on data from two stroke patients: one (S1) with left lateral medullary infarct, multiple bilateral cerebellar infarcts, small left occipital lobe tip infarct and right basal ganglia infarct, whereas the second patient (S2) shows both ischemic and hemorrhagic strokes on the right side. We found the performance results of our decoders to be asymmetric with respect to the body (R vs. L: 0.52(0.14) vs. 0.47(0.17) for S1 and 0.72(0.14) vs. 0.66(0.25) for S2), a reasonable expectation given the asymmetry in the impaired walking gait and lesions in the brain. Despite prior studies having shown better success with neural decoding using the unscented Kalman filter, we do not see noticeable improvement in accuracy (Wiener vs. Kalman: 0.51(0.14) vs. 0.50(0.17) for S1 and 0.68(0.22) vs. 0.67(0.22) for S2) except that the unscented Kalman filter's recursive algorithm may lend itself to be a better option for online decoding. With improved decoding of EEG signals from damaged brains, we hope to soon be able to correlate activity to more intentional and normal-form walking that can guide users of a prosthetic or exoskeleton.

Title: Two-dimensional control of a mouse cursor achieved by contracting the Extensor Pollicus Longus with preselected frequency bands

Authors: *I.-M. SKAVHAUG[1], R. BOBELL[2], B. VERNON[2], A. BARSZAP[2], S. JOSHI[2]
[1]Univ. of California, Davi, Davis, CA; [2]Univ. of California, Davis, Davis, CA

Abstract: We are developing a new class of Brain-Computer Interfaces (BCI) called a Brain-Muscle-Computer Interface (BMCI), which is based on electrical potentials recorded from one single surface muscle site to achieve multidimensional control of a mouse cursor. Participants learn to use this interface through an operant-conditioning paradigm based on visual feedback. We have previously demonstrated that participants can learn to navigate a cursor to targets by manipulating the surface ElectroMyoGram (sEMG) recorded from a muscle site located above the Auricularis Superior (AS; Perez-Maldonado, Wexler & Joshi, 2010). Control was achieved by simultaneously adjusting the power in two separate frequency bands selected to suit the individual participant. The AS muscle is responsible for re-orienting the ears independently of head movements, and are rarely used purposefully in humans. For this reason, and because the AS is usually accessible even to patients suffering severe neck-down paralysis, a BCI system based on sEMG from this muscle can enable individuals to control their physical environment without causing interruptions to other daily actions (e.g. speech and eye gaze). Here we report results from a newly developed portable android phone version of the BCI device (see Vernon & Joshi, 2011). We present evidence that healthy participants can use the interface by contracting the Extensor Pollicus Longus (a muscle located on the wrist that extends the thumb) - suggesting that muscles other than the AS can be used to navigate the cursor. Furthermore, because the frequency bands were preselected, and remained constant across participants, this demonstrates that each individual is able to adapt to parameters set by the device. The experimental protocol required participants to navigate the cursor to randomly presented target locations. Participants' accuracy scores significantly increased during the course of training and the cursor trajectories indicate that they moved the cursor with intentionality rather than at random. Future experiments will recruit disabled participants, focusing on the AS (or alternative accessible muscles), to establish the potential of the BMCI for this user group.

Title: Activation of human vagus nerve afferent projections via electrical stimulation of external ear: fMRI evidence.

Authors: *E. FRANGOS[1], J. ELLRICH[2,3], J. DELL'ITALIA[1], N. WISE[1], B. R. KOMISARUK[1]
[1]Dept. of Psychology, Rutgers, The State Univ. of New Jersey, Newark, NJ; [2]Cerbomed GmbH, Erlangen, Germany; [3]Hlth. Sci. and Technol., Aalborg Univ., Aalborg, Denmark

Abstract: There is anatomical evidence that a branch of the vagus nerve provides sensory innervation of the external ear. More specifically, the auricular branch of the vagus innervates the concha, which is the concave region immediately superior to the external meatus of the ear. Premise: The question addressed in the present study is whether brain regions to which vagal afferents are known to project (e.g., solitary nucleus [NTS]) can be accessed via electrical stimulation of this peripheral branch of the vagus nerve in humans. Methods: We identified activated brain regions using functional MRI. We verified the location of the NTS in the medulla oblongata by administration of a gustatory stimulus (1 cc sauce of lime juice, sugar, salt and mustard). We localized and differentiated this nucleus from the laterally adjacent nucleus cuneatus by the subjects' tapping their fingers for 40sec. Electrical stimulation of the concha of the subjects' left ear was applied using the battery-driven NEMOS® device manufactured by Cerbomed. The stimulus intensity was increased from 0.1mA in 0.1mA increments until the subjects reported a "tingling" sensation that was below noxious intensity, typically below 1mA. The non-adjustable stimulation parameters of the device were continuous 0.25msec-duration monophasic square wave pulses at 25Hz. After a 20 sec baseline resting period, the stimulation was applied continuously for 7 min, followed by a 25 min rest period. The fMRI data were analyzed using FSL (FMRIB Software Library). Results (preliminary): Brain regions with clearly delineated landmarks activated by the electrical stimulation included: NTS, raphe nuclei, thalamic VPM, nucleus accumbens, amygdala, hippocampus, insula, and postcentral gyrus - paracentral lobule (genital) and thoracic homuncular zones. Activation was also observed in the regions of the anterior hypothalamus (paraventricular nucleus), substantia nigra, and locus coeruleus. Each of the 5 subjects tested spontaneously volunteered comments that they felt particularly relaxed after the stimulation period. Conclusion: There are clinical reports that stimulation of the left vagus trunk via electrodes implanted surgically in the neck provides therapeutic benefit against epilepsy, depression and pain. The present findings suggest that because electrical stimulation of the external ear activates the major projections of the vagus

nerve, the present method of vagal stimulation could provide a less invasive therapeutic alternative.

Title: Towards optimal design of a dichotic auditory streaming brain-computer interface

Authors: *N. J. HILL[1], A. MOINUDDIN[2], S. KIENZLE[3], G. SCHALK[1,4,5,6,7]
[1]Wadsworth Center, New York State Dept. of Hlth., Albany, NY; [2]Dept. of Biomed. Engin., Univ. of Michigan, Ann Arbor, MI; [3]Briarcliff High Sch., Briarcliff Manor, NY; [4]Dept. of Neurol., Albany Med. Col., Albany, NY; [5]Dept. of Biomed. Engin., Rensselaer Polytechnic Inst., Troy, NY; [6]Dept. of Biomed. Sci., State Univ. of New York at Albany, Albany, NY; [7]Dept. of Electrical and Computer Engin., Univ. of Texas at El Paso, El Paso, TX

Abstract: Most brain-computer interface (BCI) systems require users to modulate brain signals in response to visual stimuli. Thus they may not be useful to people whose paralysis (resulting for example from advanced ALS or severe Guillan-Barré) affects their eye muscles, resulting in limited vision. To address this problem, we are developing BCIs based on shifts of attention in non-visual modalities.
We used the online BCI framework described by Hill & Schölkopf (2012, J. Neural Eng.), which exploits attention-modulation of N1 event-related potentials in response to two or more

concurrent streams of periodic stimuli. We set out to optimize this system. Our principal contrast was between the original design (unequal periods in two dichotic streams of auditory stimuli), and a design that uses strict alternation between stimuli in the two ears (equal periods). Equal periods may yield cleaner brain signal features for classification, and would allow for a more even transfer of information over time, but unequal periods may provide an additional auditory feature by which subjects could group the stimuli of the attended stream.
To determine which design provides superior online performance, 16-channel EEG measurements were taken from 16 healthy subjects. Each trial lasted 5 sec and consisted of two dichotic streams. Each stream was a periodic sequence of 7-8 tone bursts. Most of these were amplitude-modulated at 40Hz (standard), but on each trial, 1-3 of the stimuli were presented without modulation (targets). Subjects counted the targets in one stream (chosen for them by computer) while ignoring the other stream. Successful modulation of auditory ERP amplitude was rewarded with feedback at the end of each trial.
The equal-periods condition was superior for 14 out of the 16 subjects: online binary BCI classification performance ranged from 60/100 to 100/100 correct across subjects (mean 79.9%), an increase of 7.8 percentage points relative to the unequal-periods condition. The difference was significant (Wilcoxon signed rank test, N=16, p=0.002).
Finally, we explored the potential of the system for real-time control/neurofeedback applications in one additional subject. After only 30 minutes of training, the subject was able to exert continuous control over the horizontal position of a paddle in a computer game by shifting attention between two auditory streams.
Our results demonstrate that ERP modulation via shifts of auditory attention can be harnessed to create an online BCI with as few as 16 EEG electrodes; that performance can be significantly improved by optimizing the stimulus timing parameters; and that the resulting approach supports continuous BCI control.

Abstract: In Parkinson's disease (PD) medial motor areas are more impaired than those located on the lateral convexity (Goldberg, 1985). For example, relative reduction of activity in the supplementary motor area (SMA) during self-initiated hand movements has been reported (Tessa et al., 2010). In this pilot study, we investigated whether a Parkinson's disease patient could learn to voluntarily up-regulate the activity of SMA by means of real-time fMRI neurofeedback (RtfMRI-BCI).
The subject was a 52 year-old woman with mild, idiopathic Parkinson's Disease (right handed, disease duration= 39 month, akinesia type, left dominant, UPDRS I = 0, UPDRS II = 5, UPDRS III = 23, UPDRS IV = 0, Hoehn and Yahr = 2,5). After one functional localizer session, the subject underwent several sessions of real-time fMRI-BCI training to achieve voluntary control of the blood oxygenation level dependent (BOLD) signal from the bilateral SMA. During training, the subject was instructed to perform motor imagery in order to control the BOLD signal, while receiving contingent visual feedback in real-time. The influence of the learned enhanced SMA activity on motor performance was tested with interspersed blocks of a speeded, bimanual, button-pressing task (left index, right index, left middle, right middle). The subject successfully learned to control her SMA BOLD signal across RtfMRI sessions. Immediately following SMA up-regulation, response times for the initial button-press responses were elevated. These results suggest that self-regulation of SMA is possible with RtfMRI-BCI in Parkinson´s patients. However, it may be inferred that, to improve motor performance, down-regulation of SMA might be needed. To confirm these results, more subjects and longer training sessions are needed.

Title: Extraction of cross-frequency coupling features related to hand motor imagery for brain-computer interfaces

Authors: *M.-K. KIM[1], J. KIM[2], S.-P. KIM[3]
[1]Brain and cognitive engineering, Korea Univ., Anam-Dong 5-Ga, Seongbuk-Gu, Seoul, Korea, Republic of; [2]Electrical engineering, [3]Brain and cognitive engineering, Korea Univ., Seoul, Korea, Republic of

Abstract: Non-invasive brain-computer interfaces (BCIs) based on electroencephalography (EEG) aim to provide novel communication channels for those who suffer from neurological disorders with paralysis such as amyotrophic lateral sclerosis. One of the prominent ways to build a non-invasive BCI is utilizing the modulation of sensorimotor rhythms (SMRs) in the EEG induced by motor imagery. SMRs generally exhibit event-related desynchronization and synchronization (ERD/ERS) during motor imagery, which have been widely used as key features for BCIs. However, the SMR features have major drawbacks including inter-subject variability and the limited spectral bands and topographical organization. To find alternative or supplementary features to ERD/ERS, we explored the properties of the brain oscillations during motor imagery using a cross-frequency coupling (CFC) analysis. CFC reflects interactions between underlying neural circuits represented by different oscillations during cognitive tasks. We hypothesized that CFC might provide useful features about motor imagery and help improve the performance to discriminate the hand motor imagery. To verify the hypothesis, we applied the CFC analysis to the EEG data recorded during the bilateral hand motor imagery tasks. The EEG data were filtered through a bank of five bandpass filters to extract the rhythms with different frequency bands, including theta (θ: 4-8 Hz), alpha (α: 8-12 Hz), low-beta (β_L: 12-20 Hz), high-beta (β_H: 20-30 Hz), and gamma (γ: 30-40 Hz). Phase-amplitude coupling between slow and fast rhythms was evaluated by analyzing how the amplitude of fast rhythms was modulated with the phase of slow rhythms. We selected seven slow-fast rhythm pairs including θ-α, θ-β_L, θ-β_H, θ-γ, α-β_L, α-β_H, and α-γ. We observed that phase-amplitude coupling was

modulated at the contralateral sensorimotor area during the hand motor imagery. Cross-frequency phase-amplitude coupling was quantified using the modulation index, which measured dissimilarity between a phase-coupled amplitude distribution and the uniform distribution using the Kullback-Leibler divergence. Then, we used these modulation index values as features for classifying the left and right hand motor imagery. We found that using the CFC modulation index features increased classification accuracy by approximately 10% compared to the case of using ERD/ERS features. This suggests that the CFC index may provide novel features from the scalp EEG signals about the hand motor imagery and subserve the further improvement of EEG-based BCIs.

Title: Brain-computer interface design and performance standards desired by potential users with spinal cord injury

Authors: *A. A. MOINUDDIN[1], P. A. WREN[3], A. E. CHIODO[2], J. E. HUGGINS[2]
[1]Biomed. Engin., [2]Physical Med. and Rehabil., Univ. of Michigan, Ann Arbor, MI; [3]Sch. of Hlth. Sci., Oakland Univ., Rochester, MI

Abstract: Brain-computer interfaces (BCIs) allow people to operate technology without physical movement. Development of an effective and practical BCI requires understanding the end users' needs and constraints. Our previous study [1] included 61 people with amyotrophic lateral sclerosis (ALS). Current participants were drawn from the University of Michigan Spinal Cord Injury (SCI) Registry with a paralysis level C1 - C4 that can result in significantly impaired arm and leg function. A telephone survey addressed current use of assistive technologies, interest in BCI, and preferences for BCI performance and training.
Preliminary data are from 15 people with SCI (n=6 women) . Participants expressed a range of interest in differing options for BCI set-up and use. While 93% reported a willingness to use dry electrodes, only 53% were willing to use non-invasive EEG gel electrodes versus 67% willing to

have electrodes surgically implanted. All respondents would invest in 2-5 training sessions to get a useful BCI. Additionally, 69% would accept daily setup times of 10 to 20 minutes (though the minimum time of less than 10 minutes was preferred).
Respondents were also asked to define the minimum BCI performance they would consider acceptable. An accuracy of 90% would satisfy 92% of respondents. Accidental exits from standby mode only once every 3 hours would satisfy 75% of respondents. In addition, text generation of 20-24 letters per minute would satisfy 67% of respondents (though the maximum speed of 25+ letters per minute was preferred).
BCI design features rated most important were: “accuracy of BCI use” (50% of respondents), “functions the BCI would provide” (33%), and “speed with which the BCI works” (17%). Most important functions were the ability to: “communicate with someone in case of emergency” (36%), “control the room temperature” (23%), “operate a power wheelchair” (23%), and “operate a computer” (21%).
People with SCI showed interest in a BCI to help manage impairments. A majority were willing to have surgery to get a BCI and would participate in sufficient training sessions. Gel electrodes were less acceptable to people with SCI than to people with ALS (84%). People with SCI wanted faster BCI speeds. Current BCIs do not yet approach the desired levels of performance. Factors like daily set-up time, stand-by mode reliability, accuracy, and speed require future development.

Title: Movement related slow cortical potentials change after neurorehabilitation in severely affected chronic stroke patients

Authors: *O. YILMAZ[1,2], A. RAMOS-MURGUIALDAY[2,3], N. BIRBAUMER[2,4]
[1]MEG Ctr., Tuebingen, Germany; [2]Inst. Med. Psych. & Behav. Neurobio., Tübingen, Germany; [3]Tecnalia, San Sebastian, Spain; [4]Inst. di Ricovero e Cura a Carattere Scientifico, IRCCS, Ospedale San Camillo, Venice, Italy

Abstract: Introduction: Recent studies on stroke correlated the increased activation of contra-lesional, intact hemisphere with poor recovery. On the other hand, slow cortical potentials (SCPs) have been suggested as an important tool in brain plasticity research as an indicator of motor recovery after brain damage and as a positive source of information for movement decoding. In this study we investigated movement related slow cortical potentials before and after a month of neurorehabilitation in severely affected 5 chronic stroke patients presenting hand Fugl Meyer Assessment (FMA) scores of 3.7 ± 2.4 before the intervention. The neurorehabilitation was based on linking ipsilesional rolandic brain oscillations during the intention of hand opening and closing with the same grasping movements of a hand orthosis attached to the paralyzed hand and an immediate goal oriented physiotherapy session of the same movements. We expected to find a more balanced SCP activity between hemispheres after the rehabilitation in patients presenting increase in hand FMA scores.
Methods: Patients were randomly presented with visual and auditory cues corresponding to three different conditions indicating to either relax, actively open and close the healthy hand or try to open and close the paretic hand on their own pace for 4 seconds. SCPs were measured using a 16 channels EEG acticap system. Electromyographic (EMG) data was acquired using 8 bipolar Ag/AgCl electrodes and placed on antagonistic muscle pairs; one close to the forearm extensor, other on the forearm flexor, other on the external head of the biceps and the last one placed on the external head of the triceps. EEG data were filtered between 0.1 to 5 Hz. EMG onset were detected rectifying and computing the mean and standard deviation of EMG at rest. EEG data were segmented with respect to the EMG onset.
Results: SCPs produced pre- and post-movement of healthy hand did not show any difference between pre and post-treatment as expected. However, during paretic hand pre-movement and movement significant amplitude and interhemispheric changes were observed. After the treatment intact hemisphere showed increased activity at pre-movement stage, while this activity was shifting towards ipsilesional hemisphere after the movement onset. Furthermore, these increase in the SCPs during paretic hand premovement and movement correlated with increase in hand FMA. These findings indicate SCPs as a valuable functional and neurophysiological motor recovery measure.

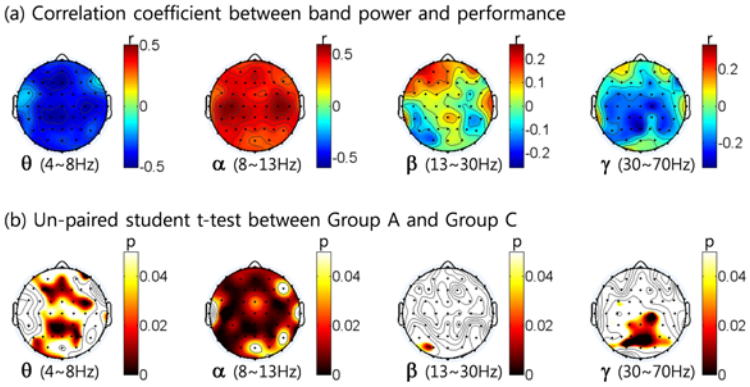
Title: Neuro-physiological difference of default mode network (DMN) between BCI able and illiteracy subject groups



Authors: M. AHN, J. H. HONG, H. CHO, S. AHN, *S. C. JUN
GIST, Gwangju, Korea, Republic of

Abstract: * Introduction
In brain computer interface field (BCI), some subjects are not able to generate sufficiently large brain signal for controlling BCI system. The proportion of these subjects, named as BCI illiteracy [1, 2], is not negligibly small. In this study, we investigated the neuro-physiological difference in the default mode network (DMN) of resting state over subjects (classified by BCI performance).
* Methods & Materials
We analyzed EEG datasets from 52 subjects under left/right hand motor imagery (MI) experimental paradigm [3]. The classification accuracy was estimated using Common Spatial Pattern and Fishers Linear Discriminant Analysis and cross-validated. According to the BCI performance, subjects were categorized into three groups - 'A' (70% accuracy or above), 'B' (60% ~ 70%), and 'C' (lower than 60%). To investigate DMN, spontaneous EEG was acquired for one minute prior to MI experiment.
* Results & Discussion
In Figure (a), θ was correlated negatively with performance on overall region, while α was positively correlated [1]. β and γ seemed not to be highly correlated with the performance; however, γ showed weakly negative correlation on the centro-parietal area, which is relevant to the finding on the causality of γ on sensory motor rhythm [2].
Figure (b) describes the statistically significant areas between the poor and moderate performance groups. Except for β, these areas are quite distinct; the frontal and mid-parietal areas for θ, overall area for α, and the mid-parietal and near occipital for γ. Noticeably, θ behavior among our findings was never reported to our best knowledge. θ may play a critical role

in attention and memory processes [4]; therefore we expect that it may be deeply related to motor imagery since a person should recall body movement for sufficient kinesthetic imagination as close as real movement during MI experiment.

Title: A multi-command spatial auditory BMI based on evoked EEG responses from real and virtual sound stimuli

Authors: *T. M. RUTKOWSKI[1,2], Z. CAI[1], N. NISHIKAWA[1], Y. MATSUMOTO[1], S. MAKINO[1], D. LOONEY[3], D. P. MANDIC[3], Z. R. STRUZIK[4], A. W. PRZYBYSZEWSKI[5]

Abstract: One of the major topics in auditory neuroscience is spatial sound localization modeling, entailing spatial attention and “cocktail party effect.” While the movement imagery and visual paradigms are routinely used in the BMI (brain machine interface) paradigms, auditory modality is still under-explored, yet has a potential to give users a vastly enhanced interfacing experience. We propose a paradigm based on spatial sound oddball concept and introduce signal processing methodology optimizing the discriminability of the attended versus ignored directions evoked responses to real or virtual sound sources in the auditory space. We present a non-invasive multi-command auditory BMI paradigm which utilizes evoked brain responses to spatially distributed sound stimuli. The method optimizes full surround horizontal plane spatial sound sources, generated from real loudspeakers or virtual sound images created with an acoustic loudness panning approach proposed. EEG signals and especially ERP responses are non-stationary, yielding classical linear methods unsuitable. Our proposed EEG preprocessing and P300 related response identification method is data-driven and is capable of separating the information bearing sources. This is achieved by analyzing in the Hilbert-Huang domain the multichannel similarity of spectral domain ridges of the P300 evoked responses. This allows clustering of common oscillatory modes revealed in the amplitude and frequency ridges related to the propagation of evoked responses among the EEG electrodes. Next, correlations in amplitude and frequency of the spectral ridges, are used in the time-domain reconstruction. The identification of these components within each channel prevents information leakage. The spatial auditory stimuli are played directly from one of the octagonally placed loudspeakers or from locations generated virtually with the amplitude panning approach. For this purpose we developed an auditory loudness spatial panning algorithm allowing to maximize the EEG P300 responses in horizontal octagonal loudspeakers’ setting. Thanks to this, subjects are able to utilize a fully octagonal loudspeaker setup (including the front and back of the head sound locations) creating the eight-commands BMI. To prove the concept of usability of surround sound sources, we used the same pink and white noises for all directions in each trial. Further experiments with various sound timbres are planed to further extend the number of commands. The developed paradigm advances contemporary multi-command auditory BMI.

Title: Detection of motor intention by using single-trial readiness potentials.

Authors: *S. YAMAUCHI[1], S. SHIMADA[2]
[1]Meiji Uni., Kawasaki/Kanagawa, Japan; [2]Meiji Uni., Kanagawa, Japan

Abstract: The present study aimed at detecting motor intention of a human subject by using a single-trial readiness potential (RP). In the present experiment, two subjects carried out a simple self-paced button press task. The experiment consisted of 49 trials with inter-trial intervals of roughly 5 s. The electroencephalogram (EEG) was recorded from 5-channels (C_Z, C3, C4, F_Z, and P_Z). By averaging the data across trials, we confirmed that RP started at around -1.5 s prior to the movement onset. Then, movement (-2.0 to 0.5 s period; the time of the button press was set to 0 s) and non-movement data (-4.5 to -2.0 s) were extracted as positive and negative samples (49 samples each) of RPs. Forty training and 9 testing samples were chosen randomly for positive and negative data. This procedure was repeated 100 times, and a cross-validation method was used to estimate the rate of correct detection of RP in a single-trial basis. Feature parameters of a single-trial RP were calculated by using training data as follows. (1) The length of the time window for detecting a single-trial RP was determined as the duration from the time when the gradient of EEG waveforms falls steeper than the threshold that was determined by using the averaged-RP, to the time when the gradient becomes shallow. If there are several periods satisfying the above criteria, the one closer to the movement onset was chosen. (2) Upper and lower limits of the EEG amplitude during the time window were calculated. The upper limit was set to the value less than the average of the baseline (-2.0 to -1.8 s before the onset of the time window). The lower limit was the difference between the minimum value in the time window and the baseline. For testing, if the amplitudes are within limits and gradients are above the threshold throughout the time window, it is regarded as detection of a single-RP. The offset of the time window was defined as a “detection time” of a single-trial RP. If RP was not detected, the onset of the time window is shifted step by step. The results showed that the average of correct detection rate was 71.4±9.5% (Hit: 75.3%, Correct-Rejection: 67.6%) and 69.2±9.3% (Hit: 45.9%, Correct-Rejection: 92.4%) for Subject A and B, respectively. The average of the detection time was -740±180ms and -783±337ms. Considering the noise level in a single-trial EEG data, the correct detection rate of about 70% seems reasonable and adequately higher than the chance-level. It is interesting that a single trial RP was detected at about -750ms in our experiment, so that early detection of a single trial RP seems realizable.

Title: Simple method to remove skin blood flow artifact in functional near-infrared spectroscopy by multidistance probe measurements

Authors: T. SATO[1], K. TAKEDA[2], R. OSU[3], I. NAMBU[1], *Y. WADA[1]
[1]Nagaoka Univ. of Tech., Nagaoka,, Japan; [2]Natl. Hosp. Organization Murayama Med. Ctr., Musashimurayama, Japan; [3]ATR Computat. Neurosci. Labs., Kyoto, Japan

Abstract: Functional near-infrared spectroscopy (fNIRS) is a noninvasive functional neuroimaging technique used to obtain cerebral activations by monitoring the concentration changes in oxygenated and deoxygenated hemoglobin (oxy- and deoxy-Hb). It has some advantages over other techniques: portability, fewer physical restrictions, freeness from electrical-noise and simplicity of use. However, undesirable artifacts such as physical movements, head posture changes, and skin blood flow (SBF) are often observed in fNIRS measurements. Particularly, SBF is caused by systemic physiological changes from superficial tissues such as the scalp and muscles that cannot be avoided experimentally and cannot be removed with conventional filtering methods.

A recent study has shown that a major part of the task-related changes in the oxy-Hb in the forehead may be due to task-related changes in the SBF during a verbal fluency task (Takahashi et al., 2011). A study using a multidistance probe arrangement (source-detector distance of 30 mm and 20 mm) has shown that SBF can be eliminated by subtracting the signal of the short channel from the signal of the long channel (Yamada et al., 2009). However, this method can only measure a narrow area since it requires many measurement probes.

We propose a new method that only uses a few short channels (source-detector distance of 15 mm) to measure a wide area. In the proposed method, we assume that temporal pattern of SBF in fNIRS signals is common in all channels and a major part of the short channel signals is SBF from past studies. The common temporal pattern of the SBF is estimated from short channels using principal component analysis (PCA) and general linear model (GLM) is applied to estimate amplitudes of SBF and cerebral activation in each channel. The design matrix contains five components: hemodynamic response function (HRF), temporal and dispersion derivatives, SBF, and constant. Proposed method can estimate cerebral activations are not affected by SBF

from oxy-Hb.
We ran simulations to assess the performance of the proposed method on simple fNIRS signals. We simulated 43 long channels that contained cerebral blood flow, SBF, and white noise, and 4 short channels that contained only the SBF and white noise, and compared the proposed method with the standard GLM that doesn't contain SBF component. The proposed method estimated exactly the amplitudes of cerebral blood flow while the standard GLM method yielded estimates larger than the theoretical values. These results suggest that the proposed method is an effective technique for the removal of SBF artifacts.

Title: Naturalistic stimuli enhance detection time for steady-state visual evoked potential-based brain computer interface

Authors: *K. NG[1], A. P. BRADLEY[2], R. CUNNINGTON[1]
[1]Queensland Brain Institute, the Univ. of Queensland, Brisbane, Australia; [2]Sch. of ITEE, the Univ. of Queensland, Brisbane, Australia

Abstract: Neural activity in the visual cortex, recorded from EEG, can be decoded in real time to determine which stimulus on a computer display a user selects by attending. Steady-state visual-evoked potential brain-computer interface systems (SSVEP-BCI) use flickering visual stimuli, with each item on the screen tagged at a different frequency, and classification methods to determine which item on the screen is attended or selected by the user. Most SSVEP BCI applications use simple stimuli such as checkerboard reversal patterns or single spots of light (LEDs). These stimuli are effective to evoke visual responses but provide no contextual meaning that allows a user to relate what they intend to represent, such as the choice between an apple or water. Hence, we developed visual stimuli that are more intuitive and naturalistic, by performing band pass filtering on natural photographs (e.g. grey-scale pictures of an apple or glass of water) such that the images retain the structure and characteristics of the original image but also have high luminance contrasts along the contours of the image which should still elicit strong neural activity from the visual cortex (SSVEPs). We compared the classification speed; that is, how

quickly our support vector machine (SVM) classification could identify the choice made by participants from their EEG visual-evoked potentials when selecting items on the screen represented by classical checkerboard patterns compared with the naturalistic stimuli. Results indicate that the detection speed is significantly faster when using naturalistic stimuli compared to using plain simple checkerboard reversal patterns. We suggest that naturalistic stimuli are able to better draw and maintain the user's visual attention than the plain checkerboard stimuli. This provides evidence towards using naturalistic stimuli for SSVEP-BCI applications.

Title: Detection of directional movement control using fNIRS optical imaging of motor cortex

Authors: *N. D. TAM
Dept of Biol. Sci., Univ. of North Texas, Denton, TX

Abstract: The present study uses functional near-infrared spectroscopy (fNIRS) optical imaging technique to decode directional arm movements based on the activation pattern of the motor cortex, as detected by the oxy-hemoglobin and deoxy-hemoglobin levels from the near-infrared signatures. Multi-channel fNIRS is used to localize the specific motor cortical activations that correspond to the motor command signals. The motor cortical activities are correlated with the direction of volitional motor execution in healthy human subjects to deduce the movement directions so that brain-derived motor command signals from optical imaging can be potentially used to control a wheelchair for quadriplegics.
The results showed that movement directions can be decoded by changes in all fNIRS signals (oxy-hemoglobin (oxyHb) signal, deoxy-hemoglobin (deoxyHb) signal, and sum of oxy- & deoxy-hemoglobin (oxyHb+deoxyHb) signals). The temporal changes in the oxyHb+deoxyHb signals from different optical sensors can be used to deduce the movement direction based on the differential changes to the near-infrared signals. This differential change in oxygen consumption at different locations within the motor cortex represents differential neural activation with respect to the movement direction. This provides a demonstration of detection of volitional motor activities using fNIRS optical imaging as a potential means to obtain noninvasive brain-derived optical signals to deduce intentional movement directions.

Title: Time-course analysis of single-trial mu-suppression during finger opposition task

Authors: *K. KANEKASU[1], S. SHIMADA[1], Y. ONO[1], M. KAWASAKI[2]
[1]Meiji Univ., Kanagawa, Japan; [2]Brain Sci. Inst., Riken/Saitama, Japan

Abstract: The present study examined the time-course of mu-suppression in a single-trial basis in order to see in what time interval after the movement onset the mu-suppression is detected most sensitively. Electroencephalogram (EEG) signals were recorded continuously by 11 pin-type active electrodes (C3, FC3, C1, C5, C4, FC4, C2, C6, Cz, Fz and Pz). Bipolar electrooculogram (EOG) were also measured. The data were filtered (0.5-30Hz) and digitized at 512 Hz. Two subjects participated in the experiment (Subject A: left-handed, and B: right-handed). Each subject carried out the finger opposition task while a cue stimulus was presented for 2 s on the left or right side of the screen (20 times each) in a random order. EOG artifacts were removed from the recorded data by using the independent component analysis (ICA). The resulting data were transformed by a continuous Morlet wavelet transform. We confirmed that there was a significant decrease of the power of 10 to 14 Hz band when the subject performed the task with their left hand compared to the baseline (-3 to -2 s before the movement onset). Similar results were observed in relatively higher frequencies (14 to 20 Hz) for the right hand condition. Next, we examined in what time interval the mu-suppression can be detected most prominently in a single-trial basis. The data for each trial (from -1 to 2s; the movement onset was set to 0 s) were divided into 24 time intervals (every 125ms). For each interval, the decay rate compared to the baseline was calculated. We regarded the detection of mu-suppression if the decay rates of both N and N+1 intervals were above the predetermined threshold (20% and 30% for subject A and B, respectively). For subject A, the detection rate of mu-suppression was the highest at 0 to 250 ms interval in the left hand condition (75%) and at -500 to -250 ms in the right hand condition (70%), while those for the intervals before the movement onset (-1000 to -500 ms) was relatively low (22.5 and 27.5 % for the left and right hand, respectively). Subject B showed similar results with the highest detection rate at 250 to 500 ms interval in both hands (70 and 80 % for the left and right hand, respectively) while the detection rates in before-onset intervals were lower (38.8 and 35 %). Although there was variability among subjects in the most

sensitive time interval to detect mu-suppression, the present result suggests the possibility that the single-trial mu-suppression can be detected early after or before the movement onset.

Title: Optimizing P300-based brain-Computer interface communication speed via error potentials

Authors: D. R. BERRY[1], K. A. COLWELL[2], *E. SELLERS[1]
[1]Psychology, East Tennessee State Univ., Johnson City, TN; [2]Duke Univ., Durham, NC

Abstract: To date, P300 BCI research has aimed to increase communication speed and accuracy. One possibility for providing faster information transfer rates is by decreasing the amount of selections required to produce a meaningful message. Previous work shows that single-trial classification of error potentials (ErrP), a unique event-related potential (ERP), can improve online performance by detecting and deleting erroneous item selections. However, nearly all of this research constructs ErrP classifiers via manual button presses on a keyboard; this method may not be translatable to clinical settings, particularly for people with severely limited motor control. Moreover, false alarms (erroneously deleting a correct selection) can be detrimental to performance, especially for users with high accuracy. Here, we propose a clinically translatable ErrP classification option by using sham feedback during a P300 BCI task. In addition, we develop an algorithm that optimizes ErrP classification, such that false alarms and the probability of correctly deleting an error are balanced to bolster information transfer rate.
Nineteen able-bodied subjects completed a P300 BCI spelling task. Stimuli were arranged in an 8x9 matrix of alphanumeric items on a computer monitor; subjects were instructed to attend to a predefined target item and mentally record each time the item ‘flashed’. Each character flashed within the matrix 2 times (125 ms SOA). Following each flash sequence sham feedback (20% error rate) was provided on a total of 300 item selections. Thirty-two EEG channels were recorded (right mastoid reference), and all of the electrode locations were used to develop a

SWLDA classifier.
Our manipulation provided distinct ERPs for correct and incorrect feedback, consistent with feedback error-related negativity. Five-fold cross-validation of the single-trial ErrPs were detected at a mean accuracy of 85.3% (AUC 0.85). After applying the optimized classification threshold, offline analyses revealed that subjects saved an average of 79 item selections (16.5%). These data suggest that ErrP classification can afford time savings (7.9 minutes out of 43.8 minutes) in producing an accurate and meaningful message.

Title: BCI-360: Full-service support for independent home-based BCI use and for translational studies

Authors: S. WINDEN[1], C. S. CARMACK[2], D. E. CORDA[2], D. J. MCFARLAND[2], D. ZEITLIN[3], L. TENTERAMANO[3], *T. M. VAUGHAN[2], J. R. WOLPAW[2]

Abstract: A major goal of brain-computer interface (BCI) technology is to restore communication and control capacities to people with severe motor disabilities. The BCI Project of the Program for Translational Neurological Research (Wadsworth Center/Helen Hayes Hospital) provides BCI-24/7, a portable 8-channel EEG-based BCI system, for independent home use by people with ALS and other disorders. This usage is enabled by Wadsworth BCI-360, a BCI2000-based software package that ensures reliable operation of the BCI device and provides a range of applications. Present applications use the P300-based visual speller format and include e-mail, limited Internet access, word-processing, games, and audio books.
BCI360: tracks system readiness over each 24-hour period (*Uptime*); controls real-time focus and window placement in the Windows XP environment to ensure correct sequencing of events (*WinMover* & *BCI Keyboard*); collects data to assess system operator (SO) training requirements and electrode cap maintenance requirements; provides system setup oversight for the SO (e.g.,

electrode impedances and artifacts) (*Diagnostics*); gives access to applications through a general-purpose configurable menu (*Main Menu*); transfers all data daily to the Wadsworth Center over the Internet and stores it redundantly to ensure fidelity (*RSync*); and compiles and displays daily use for each subject (including data on calibration exercises, usage time, applications used, and single selections) (*Report*). These data are monitored by Wadsworth personnel in order to ensure timely technical support as needed (Vaughan et al., adjacent poster). For example, over a total of 130 user-days, each of 5 BCI home users used *Diagnostics* an average of 1.24 times/day. The data showed that the average electrode impedance value exceeded 40 KOhm on only 4.5% of 465 calibration runs, and that there was no correlation between impedance and system performance (measured as selection accuracy), which may reflect the overall low impedance values.

We are now following 20 people who are using the BCI-24/7 system with BCI-360 in their homes. The results to date indicate that this technology enables independent BCI home use by people with severe disabilities who are supported by SOs with only modest training. We are modifying BCI-24/7 and BCI-360 to improve performance consistency, to accommodate other EEG features (e.g., sensorimotor rhythms), and to add new applications.

Title: Providing reliable independent BCI home use for individuals with ALS

Authors: T. M. VAUGHAN[1], *L. MCCANE[1], S. M. HECKMAN[1], D. J. MCFARLAND[1], L. TENTERAMANO[2], D. ZEITLIN[2], B. ZOLTAN[2], C. S. CARMACK[1], S. WINDEN[1], D. E. CORDA[1], J. R. WOLPAW[1]
[1]Lab. Neural Injury and Repair, Wadsworth Center, NYS Dep. Hlth., ALBANY, NY; [2]Helen Hayes Hosp., West Haverstraw, NY

Abstract: Brain-computer interfaces (BCIs) can restore communication and control capacities to people with severe motor disabilities. The BCI Project of the Wadsworth Center/Helen Hayes Program for Translational Neurological Research has translated laboratory-proven EEG-based

BCI technology into a system (BCI-24/7) that can be used by severely disabled people independently in their homes with minimal ongoing technical oversight (Sellers et al. ALS 11:449-455, 2010). This system is coupled with BCI-360, a BCI2000-based software package that at present provides a variety of applications in a P300 visual speller format.
Reliability (i.e., dependable performance) is the key to useful sustained independent BCI use. We are currently developing procedures for evaluating prospective users and then optimizing their daily use of the BCI system. After an initial confirmation that the person does not have a severe visual impairment, we conduct two one-hour evaluations to determine whether the system is effective for the person and whether the home environment and the caregiver(s) can support system use. If the results are positive, we install the BCI system in the home and over a series of 3-6 visits train the caregiver(s) as system operator(s) (SOs). This training includes placing the electrode cap, insuring satisfactory EEG signals, and initiating and overseeing device operation. At the same time, we introduce the user to the applications available through BCI-360 (Winden et al., adjacent poster). Currently these applications include: simple word processing using word prediction with both print and speech output; e-mail; limited Internet access; several games; and audio and video content (e.g., audio books, picture albums). We base initial system parameters (e.g., stimulus rate and number) for each BCI user on the EEG data recorded during the evaluations. Using the remote oversight capabilities of BCI360 (including data transfer via the Rsync transfer protocol), we monitor daily use in order to detect and address problems that may arise concerning hardware, software, SO training, and other issues. We can also interact remotely with the user and SO via *GoToMyPC* (Citrix). In addition, we conduct offline data analyses to optimize system operation. For example, recent analysis of chronic data from home users indicates that system accuracy could be improved by increasing the EEG decimation factor from its current value of 20 to 25 or higher. This change is now being implemented for an initial set of home users. If it proves effective online, we will incorporate it for our entire current home user population of 20 people and monitor its impact on each user.

Title: Spectral bandwidth of movement-related oscillations in scalp-recorded EEG activity

Authors: *D. J. MCFARLAND, W. A. SARNACKI, J. R. WOLPAW
Lab. Neural Injury and Repair, Wadsworth Ctr., ALBANY, NY

Abstract: Brain-computer interface (BCI) technology can restore communication and control to people who are severely paralyzed. BCIs use brain signals recorded from the scalp (EEG), the cortical surface (ECoG), or within the cortex. Activity in the gamma band (i.e., ≥30 Hz) has proven to be a very useful feature for ECoG-based BCI studies and is being considered for use with scalp EEG-based BCIs. The present study examined the utility of low frequency (i.e., 9-28 Hz) mu and beta activity and high frequency (i.e., 29-130 Hz) gamma activity recorded over sensorimotor cortices for classifying EEG associated with movement and movement imagery. Six subjects performed interleaved 3-min sessions of either movement or movement imagery. For each 4-sec trial, a target at either the left edge or right edge of a video screen cued left- or right-hand movement or movement imagery. The EEG was recorded from 64 electrodes referenced to the right mastoid and digitized at 1200 Hz. The amplitudes in 5 low frequency bands (i.e., 9-12, 13-16, 17-20, 21-24, and 25-28 Hz) and 5 high frequency bands (i.e., 29-36, 37-48, 69-84, 85-105, and 106-130 Hz) at C3, C4, and Cz were used as features in linear discriminant analyses.
Visual inspection of frequency-specific topographies of r^2 for movement vs. rest, imagery vs. rest, left vs. right hand movement, and left vs. right hand movement imagery showed that the differences were restricted mainly to activity below 30 Hz. The discriminant analyses confirmed these results. Overall, the data indicated that inclusion of activity above 30 Hz contributed little to the classification of the EEG associated with movement or movement imagery. This remained true even when the data were re-referenced to emphasize features with high-spatial frequencies, and even when analysis focused on the first or second 500 msec of the 4-sec trial.
It is possible that more complex movement or imagery tasks would have produced more prominent changes in high frequency activity. At the same time, these largely negative results regarding the discriminative value of EEG gamma activity indicate the need for careful evaluation of possible contamination by EMG or other artifacts in BCI studies involving high-frequency EEG activity.

Title: Enhancing brain-computer interface Performance in an ALS population: Checkerboard and color paradigms

Authors: *D. RYAN[1], S. THROCKMORTON[2], L. M. COLLINS[2], K. M. CAVES[2], E. W. SELLERS[1]
[1]East Tennessee State Univ., Johnson City, TN; [2]Duke Univ., Durham, NC

Abstract: Noninvasive brain-computer interface (BCI) provides non-muscular communication via detection of EEG features. Compared to traditional means of communication, BCI communication is slow; however, improved techniques (e.g., paradigm manipulation and/or target classification algorithms) have been used to optimize speed and accuracy. In a non-disabled population, and in pilot data from three subjects with amyotrophic lateral sclerosis (ALS), the “checkerboard” presentation paradigm provided better performance than the standard “row/column” presentation paradigm. The checkerboard controls for adjacent flashes of items and ensures that once an item has been presented it will be excluded from at least six subsequent flash groups, which improves identification of target stimuli. In non disabled subjects, a condition that changes groups of gray matrix items to one of nine unique colors improved performance over that observed when groups of gray matrix items change to white. The color stimuli decrease non-target distraction and improve target classification as compared to the standard white stimuli. To determine if these improvements generalize to an ALS population, a within participant design tests all three paradigms. Current data suggest that the checkerboard improves performance as compared to the row/column. In addition, color stimuli enhanced performance and participants prefer the color stimuli over the white stimuli. The results suggest matrices including checkerboard and color stimuli provide more efficient communication and higher user satisfaction in an ALS population.

Title: A longitudinal investigation of non-invasive P300-based brain-computer interface

Authors: *K. E. BROWN[1], D. B. RYAN[2], J. A. ARMSTRONG[2], E. W. SELLERS[2]
[1]Psychology, Brain-Computer Interface Lab., Johnson City, TN; [2]Psychology, East Tennessee State Univ., Johnson City, TN

Abstract: Brain-Computer Interface (BCI) provides a method of communication for severely disabled individuals who are unable to communicate due to significant loss of muscle control. People diagnosed with amyotrophic lateral sclerosis (ALS) can typically derive the most benefit from BCI use, as ALS causes inexorable loss of muscle function that will eventually result in locked-in syndrome. The BCI presented here operates independently of muscle control. Event-related potentials (ERPs) are extracted from the EEG and analyzed. Items (i.e., alphanumeric characters and keyboard commands) attended to by the subject should produce a P300 ERP, and the unattended items should not. The computer uses a stepwise linear discriminant analysis to classify the items as attended or unattended. Many studies have shown that people disabled by ALS can communicate using the P300 BCI; however, no study has systematically examined BCI performance longitudinally. The current study examines the relationship between disease progression, BCI performance, and several other factors that may contribute to BCI performance. Presently, five patients are enrolled in the study and data are collected in intervals of approximately eight weeks. Each session involves administering the ALSFRS-r as a means of tracking disease progression followed by four EEG tasks including: resting EEG, cognitive task (counting backward by 7), an oddball task, and copy spelling task. Preliminary data suggest that BCI performance remains stable despite progressive loss of movement. Alpha power spectra is greater at rest than during the cognitive task, suggesting an appropriate response to cognitive load. The oddball task generated a P300 for attended stimuli, and no P300 for unattended stimuli. ALSFRS-r scores decreased by 1.8 points on average, measured over a 10.2 week period. Across the five subjects, mean BCI copy spelling accuracy was 88% with an average subject variability of 12%. Overall, the results suggest that BCI performance remains stable as disease progression continues. We will continue to monitor this relationship over time and compare it to data collected from healthy individuals.

Title: Utilizing a language model to improve dynamic data collection in P300 spellers

Authors: B. MAINSAH, L. M. COLLINS, K. COLWELL, *S. THROCKMORTON
Electrical and Computer Engin., Duke Univ., Durham, NC

Abstract: P300 spellers rely on event-related potentials (ERPs) that occur in scalp-measured electroencephalography (EEG) to determine the character that the BCI user intends to spell. The P300 speller provides a noninvasive method of communication that is not reliant on physical movement thus providing a method of communication for those suffering from severe neuromuscular disabilities that might preclude the use of other assistive devices. The speller operates by monitoring the EEG response of the user as subsets of characters are flashed on a monitor; when the flashed subset contains the character the user desires to spell, an ERP occurs. However, single ERPs tend to have low signal-to-noise ratios (SNR). In order to increase SNR and thereby increase classification performance, each character is flashed multiple times, and the responses are averaged. Several studies have demonstrated that spelling speed and accuracy is improved by adaptively selecting the number of flashes per character. However, these methods tend to rely in some form on past performance of participants to control the data collection rather than on a subject-independent, probabilistic method. A probabilistic method has the advantage of both assessing the quality of the data currently under consideration as well as allowing for the incorporation of *a priori* knowledge of the language of the user to increase spelling speed. The Dynamic Stopping algorithm used in this study maintains a probability distribution over characters; each classified flash response is integrated into the model via a Bayesian update. This algorithm has been demonstrated to significantly increase spelling speed and accuracy for subjects with a wide range of abilities to use the system [Colwell et al., 2011]. The Dynamic Stopping algorithm is expanded here to include a language model which is implemented by initializing each character prior to data collection based on the previously spelled character. This potentially reduces the time required for the probability of the intended character to reach the threshold used to stop data collection. We present the results of an experiment testing subjects' spelling accuracy and speed under the Dynamic Stopping and Dynamic Stopping plus Language Model algorithms.

Title: Sparse structured probit regression for online channel selection and classification for the P300 speller

Authors: *K. A. COLWELL, L. M. COLLINS, K. D. MORTON
Electrical & Computer Engin., Duke Univ., Durham, NC

Abstract: The P300 Speller is a device that allows users to control a computer via measured multi-channel electroencephalogram (EEG) data without requiring neuromuscular control. As such, it provides an option for communication to populations with severe physical limitations. Home and clinical use of the P300 Speller may be better facilitated by improving the ease-of-use of the physical interface, increasing the device's accuracy, and improving system robustness to installation. We address each of these aims by introducing Sparse Structured Probit Regression (SSPR), a method for training a linear classifier that generalizes the Relevance Vector Machine classifier [Bishop 2000] to perform channel selection and classification concurrently. The generalization allows the model to search for solutions that are not only sparse in features, but sparse in channels as well; this equates to a de facto channel selection whose number of informative channels is determined from the data, rather than a priori. The resulting sparsity among channels may demonstrate that certain channels of the electrode cap are not informative and thus may be removed, easing installation, while the classifier determined by SSPR also retains or increases the accuracy obtained using a standard set of 8 channels. The ability to select channels also provides protection against installation errors and longitudinal spatial changes in brain response. We present accuracy and channel selection results obtained by simulating the application of SSPR to real BCI data. The model is then modified further to perform online training, following the methodology of [Sato 2001], such that the training process of the classifier is performed as training data is collected. Using Online SSPR, users who would benefit from collecting additional training data may do so, increasing system accuracy, and users who do not need to collect the standard amount of training data can stop training early, saving training

time. We present accuracy and channel selection results obtained by applying Online SSPR to real data, and compare these results to both results obtained with standard methods, and Batch (standard) SSPR.

Title: Functional recovery and cortical reorganization after Brain-Computer Interface-based neuromuscular electrical stimulation training in chronic stroke: A case study

Authors: *T. ONO[1], M. MUKAINO[2], J. USHIBA[1]
[1]Keio Univ., Kanagawa, Japan; [2]Asahikawa Med. Univ., Asahikawa, Japan

Abstract: * Ono T. and Mukaino M. contributed equally to this work.
Previous studies suggest that brain-computer interface (BCI)-based rehabilitation is useful for promoting functional recovery of paretic hand movement in chronic stroke patients. Although these studies show the effectiveness of training with BCI-driven devices, e.g. orthosis, robot, or electrical stimulation, the extent of the contribution of the BCI system per se is not clear. In this study, we compared neuromuscular electrical stimulation (NMES) with BCI-driven NMES, employing an ABAB design.
One subject with stroke participated in this study. In epoch A, the subject received NMES on the paretic extensor digitorum communis (EDC) for 60 min per day, 5 days per week for two weeks. The subject was instructed to imagine finger extension during the stimulation. In epoch B, BCI-driven NMES training was performed. During each trial, the subject imagined finger extension for 4 s following an imperative cue. The EDC was stimulated when sustained (>1 s) motor imagery was detected in the task period as event-related desynchronization of the electroencephalogram (EEG). Epoch B was carried out for 60 min per day, 5 days per week for two weeks except the last epoch B that was performed for three weeks. Surface electromyogram (EMG) of the paretic EDC, EEG and functional magnetic resonance imaging (fMRI) were monitored at the end of each epoch as evaluations of motor functions and cortical activities. In addition, Fugl-Meyer Assessment (FMA) and modified Ashworth scale were measured as

evaluations of clinical scores.
Before starting the training, attempted finger extension was associated with weak EMG activity and bilateral cortical activation. Although several previous studies have shown that NMES could be effective for rehabilitation of chronic motor impairments after stroke, epoch A was associated with no improvement except for a slight increase in FMA score. In contrast, epoch B, the BCI-training epoch, was associated with marked augmentation in EMG activity, localization of cortical activity and improvement in clinical scores. Improvement in the clinical scores continued beyond the first epoch B, however, the localization of cortical activity on fMRI and the increase in EMG activity were negated during the second epoch A, indicating the significant contribution of the BCI system to these positive results. These results suggest the superiority of closed-loop training with BCI-driven NMES to open-loop NMES for chronic stroke patients.

Title: Development of brain-computer interface system for upper extremity-rehabilitation with task-oriented design

Authors: *J. USHIBA[1], A. MORISHITA[2], T. FUJIWARA[3], K. ABE[4], A. NISHIMOTO[3], M. KAWAKAMI[3], D. KAMATANI[3], M. LIU[3]
[1]Dept Biosci & Informatic, Keio Univ., Yokohama, Japan; [2]Grad. Sch. of Keio Univ., Yokohama, Japan; [3]Keio Univ. Sch. of Med., Tokyo, Japan; [4]Keio Univ. Hosp., Tokyo, Japan

Abstract: Motor imagery based brain-computer interface to drive motor-driven orthosis or neuromuscular electrical stimulation has been expected as one of novel rehabilitative measures for severe motor disorder due to stroke. Previous pilot studies with single-case or case-series clinical experiments showed the increase of motor-related desycnrhonization of the sensorimotor rhythm in EEG, improvement of voluntary EMG in the paretic hand, and increase of actual clinical score assessing upper extremity motor function. Though these results have generated a great deal of interest in clinical application, a system development for further easy-to-use must be needed. Time spent for both placement of EEG electrodes and calibration of parameters in an EEG feature classifier are not negligible when the system is introduced to clinical scene so that

simplification of BCI setting must be needed. Moreover, arrangement of BCI paradigm with task-oriented design is needed to stimulate patients' motivation in daily training. Therefore in this study, we developed a prototype of brain-computer interface system for upper extremity-rehabilitation with task-oriented design. The system is consisted of a headphone-style EEG holder with a pair of dry electrode, a touch panel laptop, and a motor-driven prehension orthosis combined with neuromuscular electrical stimulator, formed based on reflex inhibitory splints. A LED was on the distal end of the orthosis to display the cue. We first tested the feasibility of this developed device in views of engineering and human ergonomics. Skin-electrode impedance assessment evidenced that the headset sufficiently held the EEG electrode on the scalp, and a questionnaire with Quebec User Evaluation of Satisfaction with Assistive Technology revealed that the device is ready for clinical use. The orthosis was certificated by both occupational therapists and orthotists to prevent increase of spasticity. We then tested the developed device in repetitive reach-to-grasp training in stroke participants. Participants were asked to reach their hand to a target peg using balanced forearm orthosis, and grasp it by motor driven action. Participants then moved their hand outside the pegboard, and BCI sequence was started. After a 5 s rest, a visual cue to attempt finger-opening movement was given. The motor-driven orhosis opened their finger if more than 5% of ERD by attempting finger movement was observed over the contralateral parieto-temporal region. All the participants successfully completed 10 days of 40-min training without any adverse effect. From these results, we concluded that the developed BCI system is practically useful for clinical scene.

Title: Modulation of event-related desynchronization during hand motor imagery with transcraial direct current stimulation

Authors: *M. OTO[1], Y. SHINDO[2], J. USHIYAMA[3], A. KIMURA[2], M. LIU[2], T. FUJIWARA[2], J. USHIBA[3]

[1]Keio Univ., Yokohama City ,kanagawa Prefecture, Japan; [2]Keio Univ., Tokyo, Japan; [3]Keio Univ., Yokohama, Japan

Abstract: The event-related desynchronization (ERD) of Electroencephalogram (EEG) is supposed to reflect motor preparation and appear during motor execution and motor imagery. Since ERD is a considerable marker representing temporal excitability of the sensorimotor neural circuit, extrinsic feedback of ERD caused by attempting paretic hand movement is expected to promote motor learning and to improve motor function. Stroke patients, however, show little ERD resulting in a limited usage of BMI intervention. Possible combined technique to enhance ERD is therefore awaited.

Transcranial direct current stimulation (tDCS) is one candidate to modulate ERD. Anodal tDCS can increase excitability of the motor cortex so that ERD is expected to be increased during and after stimulation. This study tested its hypothesis by comparing the amplitude of ERD during hand motor imagery before and after applying tDCS over primary motor cortex. ERD during stimulation was also measured to assess the extent of the tDCS effect.

Six healthy subjects were asked to imagine their right fingers extending. They started right hand motor imagery after receiving a visual cue. EEG was recorded over the left motor cortex, and was used to calculate ERD. Then anodal tDCS (10 min, 1 mA) was used to increase the cortical excitability of left motor cortex. Two different types of conditions were tested in this study. The one condition applied tDCS prior to 20 times of 5-s motor imagery task ("Preceding" condition). Another condition applied tDCS during the same motor task ("Simultaneous" condition). A control condition with sham stimulus during the motor task was also tested. All the condition was conducted with a randomized sequence on different days in each subject. ERD was calculated at the periods before tDCS, during tDCS, and after tDCS (three times), and their amplitudes were compared.

The ERD significantly increased in both "Preceding" and "Simultaneous" tDCS conditions, and larger ERD was seen in the latter condition (increased 13.7 ± 21.1 %). Enhancement of ERD lasted by 30 minutes in "Simultaneous" condition, which was 15 minutes longer than "Preceding" condition. ERD value did not increase in sham condition. These findings suggest that ERD is increased by anodal tDCS, and the enhancement of ERD and its carry-over effect are larger when stimulation was applied during the motor task, rather than after motor task. Though this preliminary study was achieved in healthy individuals, the result gives us a possibility to use tDCS during ERD-based BMI training for further efficacy in rehabilitation.

Title: Event-related desynchronization during hand motor imagery is correlated with excitability of both primary motor cortex and spinal motoneuron

Authors: *M. TAKEMI[1], A. KIMURA[2], M. LIU[2], Y. MASAKADO[3], J. USHIBA[4]
[1]Grad. Sch. of Sci. and Technology, Keio Univ., Yokohama, Kanagawa, Japan; [2]Rehabil. Med., Keio Univ. Sch. of Med., Shinjuku, Tokyo, Japan; [3]Rehabil. Med., Tokai Univ. Sch. of Med., Isehara, Kanagawa, Japan; [4]Biosci. and Informatics, Fac. of Sci. and Technology, Keio Univ., Yokohama, Kanagawa, Japan

Abstract: There is increasing interest in electroencephalogram (EEG)-based brain-computer interface (BCI) as a tool for rehabilitation of upper limb motor functions in hemiplegic stroke patients. This type of BCI often exploits the oscillations in the EEG occurring in the mu and beta bands recorded over the sensorimotor areas, and their event-related desynchronization (ERD) following motor imagery (MI) is believed to represent increased excitability of the sensorimotor cortex. However, it is not well understood if the temporal excitabilities at the cortical and spinal level in the motor system are correlated with ERD. The purpose of this study was to assess the association of ERD with primary motor cortex (M1) and spinal motoneuron excitability during hand MI using electrophysiological techniques.
This study comprises two experiments. Ten healthy subjects were recruited for each experiment. The subjects received real-time visual feedback of the ERD magnitude of EEG signals recorded over the contralateral hand sensorimotor area while they performed a MI task.
In Experiment 1, each subject performed 30 trials comprising 7 s of rest followed by 5 s of MI of right wrist extension. M1 excitability was tested by motor evoked potentials (MEPs), intracortical inhibition (ICI) and intracortical facilitation (ICF), using transcranial magmetic stimulation (TMS) of the contralateral hand area of M1. TMS was applied when ERD exceeded 5% or 15% thresholds during MI. EMG was recorded from the extensor carpi radialis.

In Experiment 2, each subject performed 50 trials comprising 7 s of rest followed by 5 s of MI of right thumb abduction. Spinal motoneuron excitability was assessed by F wave persistence recorded from the abductor pollicis brevis following right median nerve stimulation at the wrist level. Electrical stimulation was applied when ERD exceeded 5% or 15% thresholds during MI. One-factor repeated measures ANOVA showed there was a main effect of ERD for MEP amplitudes (p = .005), ICI (p = .0002) and F wave persistence (p = .010), but not ICF (p = .34). Post-hoc analysis revealed that MEP amplitudes were significantly larger at ERD 5% (p = .026) and ERD 15% (p = .016) compared to rest. ICI was significantly reduced at ERD 15% compared to rest (p = .004) and ERD 5% (p = .023). F wave persistence was significantly increased at ERD 15% compared to rest (p = .004), and tended to increase at ERD 15% in comparison with the ERD 5% (p = .084).
Our findings suggest that ERD magnitude during hand MI is an index of the temporal excitability of M1 and spinal motoneurons. Using BCI to associate ERD with upper limb training may be beneficial in stroke rehabilitation because it enhanced corticospinal tract excitability.

Title: Clinical application of a newly developed Brain Computer Interface training system to patients with severe hemiparesis.

Authors: *T. FUJIWARA[1], A. NISHIMOTO[1], M. KAWAKAMI[1], J. USHIBA[2], A. MORISHITA[2], D. KAMATANI[1], M. LIU[1]
[1]Keio Univ. Sch. of Medicie, Shinjuku Tokyo, Japan; [2]Keio Univ., Yokohama Kanagawa, Japan

Abstract: Brain
computer interface (BCI) training has been developed for upper extremity (UE) rehabilitation for patients with severe hemiparesis. It has been reported that BCI training improves UE motor function in patients with stroke. BCI can directly translate brain signals for the intension of moving fingers into commands for

control of a motor-driven hand orthosis. BCI systems estimate a patient's motor intention from the amplitude modulation of the mu rhythm (event related desynchronization; ERD).
Clinical application of BCI to rehabilitation,
however, has beenlimited because of its feasibility. We developed a new compact BCI system and applied it to clinical rehabilitation setting. In this new BCI system, we detect ERD using a pair of dry electrodes, which are attached to a headphone. It takes less than 5 minutes to put on the electrodes by using this headphone systems. Patients wear the motor-driven orthosis, which extend their paretic fingers triggered with ERD. Using this orthosis, patients can pick up and release pegs.
We applied this new BCI system to 6 patients
with severe hemiparetic stroke. BCI training consisted of a 40-min session per day and was performed for 10 days. Their mean time from stroke onset was 1712 days and mean age was 51.5 y.o. Before and after the BCI training, we assessed Fugl-Meyer upper extremity motor function (FM-U) and motor activity log (MAL) scores. We also measured short intracortical inhibition (SICI) of the motor cortex with paired pulse transcranial magnetic stimulation and reciprocal inhibition (RI) of flexor carpi radialis (FCR) H reflex in the affected forearm.
After the BCI training we found significant improvements of FM-U and MAL scores. We found disinhibition of SICI of the unaffected hemisphere in some patients before the BMI training. This disinhibition became less after the BCI training. The BCI training also increased the magnitude of RI.
Clinical
use of our new BCI system improved UE motor function and daily use of the paretic hand. The pinch and release are important functions to use the hand in activities of daily living. Our BCI system can improve these functions and improve the amount of use of the paretic hand. It is supposed that our BCI training may induce some spinal and cortical plastic changes.

Title: Categorizing independent components based on spatial, temporal, and spectral features.

Authors: *R. J. FERNANDEZ[1], S. M. GORDON[1], J. M. VETTEL[2], S. KERICK[2], J. C. BRADFORD[3], V. LAWHERN[4], A. URBAN[2], K. WHITAKER[2], K. MCDOWELL[2]

Abstract: Independent component analysis (ICA) is commonly employed in neuroimaging research to separate signals into maximally independent components, including EEG recordings believed to represent a linear mixing of brain and non-brain sources. Previous research has shown that ICA is an effective tool for isolating brain sources of interest in a variety of experimental tasks.
Typically, to identify brain-dominant independent components (ICs), an experimenter must manually inspect each IC after decomposing the EEG data. Each IC is first fit to a dipole model within a brain volume using either a standard MNI/Talairach template or a subject-specific MRI scan. The experimenter next cross-references the dipole fit with the IC activation plot, the dipole projection onto the scalp, and spectral measures such as log power in specific frequencies. Based on these features, the IC is then categorized as a brain, non-brain, or mixed source IC. Our group is exploring the analytic utility of seven IC categories, and to facilitate this project, we developed a categorization rubric and confidence assessment for IC features identified by multiple experimenters.Using this rubric, experimenters categorized ICs for EEG data obtained from many subjects. An expert system then learned a set of Bayesian rules for IC categorization given an input feature space and the experimenter-labeled ICs. The system returned both the most likely category as well as a confidence measure based on the marginal distribution returned by each rule. Initial results indicate that such an approach can adapt to specific experimental goals, i.e. the categorization is rubric dependent. In addition, the system can provide a reliable label and descriptive feature list for each IC to minimize burden on the experimenter during manual inspection as well as maximize the objectivity of the categorization process.

Abstract: Brain-Computer Interface (BCI) experiments often utilize simplified environments and tasks to reliably extract brain signals that are diagnostic for either subject behavior or intent. Recently, BCI research has expanded to a broader range of applications, including targeted performance enhancement for healthy individuals in complex, multi-tasking environments. In such contexts, limiting BCI analysis to brain signals may produce suboptimal results.
Fourteen Army Sergeants completed six experimental missions that simulated vehicle operations on a low-threat security patrol through a desert urban environment. While scalp EEG was recorded, the Vehicle Commander (VC) sat in a 6-DOF ride motion simulator and performed mission tasks, including route planning and navigation, target detection, and radio communications. The number and frequency of simultaneous tasks varied during the mission, with higher taskload (more concurrent tasks) during travel in the city sector and lower taskload (sparse tasking) during travel from the sector to the city outskirts.
This analysis examined the predictive value of specific classes of independent components (ICs) for identifying VC taskload on a moment-by-moment basis. EEG data was transformed into maximally independent sources and separated into specific classes using spatial, temporal, and spectral features: (1) brain dominant, (2) eye dominant, (3) brain plus non-brain, and (4) non-brain dominant ICs. We built classifiers using various IC class combinations and projected only selected sources to the scalp. A two-stage classification approach used a support vector machine (SVM) to classify average spectral power features, and a Dynamic Bayesian Network (DBN) filtered and classified the raw SVM values.
The results indicate that no single source type was point-wise dominant across all six missions for a participant; instead, each IC class captured task-relevant processes, and their combination enabled optimal classification. These results demonstrate the feasibility of BCI applications in more complex domains and the value of both brain and non-brain, task-related sources.

Abstract: The goal of this research is to implement the value of developed mobile and wireless EEG system for monitoring driver's fatigue. Four-channel mobile and wireless EEG system, called Mindo-4, acquires EEG signals from the forehead area. Results showed the average correlation between dry and wet EEG signals were 98.14%. We then implement the dry sensor device to conduct the sustained-attention experiment in a realistic dynamic driving simulator. Support vector regression was used for modeling the spectral pattern to predict driver's fatigue state.

Eight voluntary adults participated in a sustained-attention driving task for 1.5 hours after lunch which would be easy to let the subject fall asleep and induce their fatigue level in the experiment. Each subject wearing the Mindo-4 EEG device (figure 1), sat inside the vehicle to perform the experiments. The duration time from the response to the deviation event, denoted as the response time (RT), was used as an indicator to determine subject's fatigue level. To examine the feasibility of the estimation system, experiment results in Figure 2 demonstrate the prediction performance of using Mindo-4 with dry EEG sensors in the driving environment. Furthermore, experiment evidences including power spectral analysis and prediction performance had showed the feasibility of using the mobile and wireless

EEG system can obtain good performance and be applied in the real world.

Title: Improving EMG-based gesture control by using symmetric bimanual gestures

Authors: A. AKHTAR[1], J. NORTON[1], *S. N. BESHERS[2], T. BRETL[1]
[1]Univ. of Illinois, Urbana, IL; [2]U Illinois Urbana-Champaign, URBANA, IL

Abstract: The use of gestures as an input device for controlling devices and other multimedia have seen great increases in recent times. Several studies have investigated using electromyography (EMG) as the signal source for characterizing these gestures. A recent study by Kim et al. in 2008 [1] explored the use of a single-channel EMG placed on the wrist to control an RC car with four gestures. We extend this work by performing corresponding bimanual gestures for better accuracy, as well as

improving on the timescale of classification. Our results suggest that bimanual gestures improved classification accuracy, Linear Discriminant Analysis (LDA) performs better than the methods used in [1], and that the windowing method used in this paper allows for classification at a faster rate.

Title: A p300 based cognitive assessment battery for severely motor impaired and overtly non-responsive patients

Authors: A. KIRSCHNER, *A. M. OWEN, A. HAMPSHIRE
Brain and Mind Inst., Brain and Mind Inst., London, ON, Canada

Abstract: Diagnosing disorders of consciousness is notoriously difficult, with estimates of misdiagnosis rates as high as 40%. Moreover, recent studies have demonstrated that patients who do not show signs of volitional motor responses can exhibit preserved command following as detected by functional magnetic resonance imaging (fMRI) and electroencephalography (EEG). However, although these patients clearly retain some cognitive abilities, administration of standard neuropsychological tests is impossible with such severally motor impaired patients. Consequently, the extent of their cognitive function is unknown.
In the current study, we sought to develop a p300 event related potential (ERP) paradigm in healthy subjects to assess three distinct components of higher cognition in the absence of motor output.
First, to assess covert command following subjects were instructed to attend to a target auditory stimulus, counting each time it occurred, while ignoring distractor auditory stimuli. At the single subject level, 10/10 individuals displayed a significantly larger p300 response to attended vs. unattended words, demonstrating that selective attention can be measured using only electrophysiological markers and used to assess command following.

In order to assess working memory capacity we adapted a standard neuropsychological test (digit span) to use a similar p300 response mechanism. Subjects were instructed to remember 4-8 words in order over a 10 second delay period and asked to retrieve the letter in a given position when the delay was over. Subjects indicated their answer in each trial by attending to the word corresponding to their response. In 8/10 subjects, the p300 responses were significantly larger to correct vs. incorrect words, indicating that they had correctly solved the majority of the problems and could signal their answer using selective attention.
Finally, to assess reasoning ability, we adapted a verbal reasoning task in the same manner. Subjects were given sentences describing the relative position of two items (i.e. “boss does not precede seal”) and asked to report which of the two items logically came first. P300 responses were significantly greater to stimuli corresponding to correct vs. incorrect answers in 8/10 subjects, again demonstrating that they had successfully solved the majority of the problems. These results demonstrate that covert control of attention, as measured by the p300 ERP, can be used to assess attention, working memory and reasoning abilities with a high degree of reliability. We propose that this approach could provide a viable cognitive assessment battery for patients with disorders of consciousness.

Title: *In vivo* two photon microscopy reveals immediate microglial reaction to implantation of microelectrode through extension of processes

Authors: *T. D. KOZAI[1], A. L. VAZQUEZ[2], C. L. WEAVER[1], S.-G. KIM[2], X. CUI[1]
[1]Bioengineering, [2]Radiology, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Penetrating cortical neural probe technologies allow investigators to record electrical signals in the brain. Implantation of probes result in acute tissue damage and microglia density increases around these devices over weeks. However, the mechanism(s) underlying this encapsulation is not well understood in the acute temporal domain. Using two-photon in vivo

microscopy, microglia at a depth of ~200 µm below the surface of the cortex were imaged every minute in mice with green fluorescent protein-expressing microglia. Following probe insertion, nearby microglia immediately extended processes toward the probe at (1.6 ± 1.3) µm/min during the first 30-45 min, but showed negligible cell body movement for the first six hours. Six hours after probe insertion, microglia at distances <130.0 µm ($p=0.5$) from the probe surface exhibit morphological characteristics of transitional stage (T-stage) activation, similar to the microglial response observed with laser-induced Blood Brain Barrier (BBB) damage. T-stage morphology and microglia directionality indexes were developed to quantify the microglial response to implanted probes. Evidence suggesting vascular reorganization after probe insertion and distant vessel damage was also observed hours after probe insertion. A precise temporal understanding of the cellular response to microelectrode implantation will facilitate the search for molecular cues initiating and attenuating the reactive tissue response.

Abstract: Our overall goal is to determine particular device design features that are associated with long-term recording performance of implanted neuroprosthetic devices. In these

experiments we have examined a design space including 12 different devices with different shank widths, open architectures, electrode placements, and electrode designs. Animals were implanted and recordings performed three-times a week for 30 days while animals were performing a trained task. Following the last recording session animals were perfusion fixed with 4% paraformaldehyde and brains prepared for high resolution, high throughput, multichannel, 3D imaging using an Olympus spinning disc confocal system. Tissue slices were prepared to include the entire device within a single section. Nuclei labeled with Hoechst 3453; neurons labeled with NeuroTrace; and astocytes and microglia labeled using immunohistochemistry to GFAP and Iba-1, respectively. All images were collected as a series of optical sections through the entire tissue slice. A series of overlapping images were collected around each site resulting in data collection of as much as a 2x2x0.1mm tissue volume. FARSIGHT image analysis was performed on each data set providing detailed tracing of microglia and astrocytes and mapping of all neurons, microglia, and astrocytes relative to both the device shank and individual electrodes. In addition, analyses have been completed describing different classes of microglia, changes in astrocyte morphologies, neuron distributions, and changes in their distribution relative to control brain samples. These data are being correlated with electrophysiological recording data to identify critical device features and electrode performance.

Abstract: Astrocytes are glial cells of particular importance for studying several disease mechanisms, as well as brain reaction to the presence of implanted devices. Astrocyte nuclei detection is a complicated task due to the presence of microglial cells, neurons and endothelial nuclei. In addition, astrocytes are characterized by a complex octopus-like morphology, and complex cell-cell and cell-vessel contact patterns. Given that astrocyte nuclei and processes are stained in different channels, there is a substantial challenge for automated quantification methods. This work introduces a novel machine-learning method for the quantification of astrocytes, based on a combination of morphological and associative features derived from 3D multi-channel confocal microscopy images. Astrocyte roots, i.e. regions of basal convergence of astrocyte processes, are strong indicators of the presence of astrocyte nuclei within their proximity. In the proposed method, nuclei classification and root detection are effectively coupled in a 2-stage classification scheme, employing active learning so as to allow the expert biologist to provide the most informative training examples. Starting from the identified roots, a tree-based tracing algorithm is applied to enable quantification of astrocyte morphology. Experimental results demonstrate the usefulness of the proposed method for quantifying tissue perturbations caused by implanted neuroprosthetic devices.

Abstract: One of the main medical challenges involves the development of therapies to improve the quality of life of people suffering from different types of body paralysis, through the reestablishment of its sensory and motor functions. Brain-machine interface (BMI) emerges as a potential candidate, allowing the control of paralyzed body parts directly by brain activity. Chronically implanted multielectrodes are one of the fundamental components of an invasive BMI, recording neural activity directly from the brain parenchyma. However, before this technique can be effectively available to human clinical trials, it is necessary to comprehensively characterize its impact on the nervous tissue. Here we evaluated the impact of chronic implanted tungsten multielectrode arrays on the distribution and morphology of some classes of inhibitory neurons across rat's motor cortex. In addition, we also correlated the results of cell distribution with electrophysiological signal, in order to estimate the impact of post-implant elapsed time on neuronal recordings. Chronic electrode arrays were well tolerated by the nervous tissue, with recordings remaining viable for up to 6 months after implantation. A restricted neuronal loss and glial activation were observed on the implanted sites. In addition, an interesting result supports future application, since both morphology and distribution of inhibitory neurons were not broadly affected. Altogether, our results suggest that tungsten electrodes can be defined as a feasible candidate to future human clinical interventions involving BMI.

Title: Normal ATF-3 and cJUN expression in sensory neurons of peripheral nerve interfaced animals despite nerve stretching

Authors: *V. H. DESAI[1], S. BHETAWAL[1], N. KHOBRAGADE[2], C. WATSON[2], A. NGUYEN[2], J. SEIFERT[2], M. ROMERO-ORTEGA[2]
[1]Dept. of Bioengineering, Univ. of Texas At Arlington, Arlington, TX; [2]Univ. of Texas At Arlington, ARLINGTON, TX

Abstract: Peripheral nerve interfaces (PNI) have been shown to record motor intent in amputee volunteers and to elicit specific sensation modalities after electrical stimulation. While several types of PNI exist, those implanted directly into the nerve provide higher sensitivity in the recording of single unit neural spikes. However, peripheral nerves are intrinsically elastic and movement of interfaced nerves likely exerts mechanical stress at the electrode-nerve interface. Whether such movement causes tissue micro-injuries and possibly contributes to signal decay over time, is currently unknown. Transcription factors such Activating Transcription Factor ATF-3 and cJUN are established markers of neuronal cell damage and nerve regeneration, respectively. In PNIs such as the Regenerative Multielectrode Interface (REMI), in which the nerve is transected to implant the electrode array, one can anticipate an initial and temporal increase in both ATF-3 and cJUN. In contrast, a persistent expression of both transcription factors, would indicate continued micro-injuries caused by the mechanical mismatch at the electrode/nerve interface. Here we evaluated the expression of ATF-3 and cJUN in the L4/L5 Dorsal Root Ganglions (DRG) of 18 adult Lewis rats, implanted with REMI in the sciatic nerve. REMI consists of an 18 electrode array fixed in the lumen of a 7 mm polyurethane conduit. Controls were implanted with an empty conduit. Histological evaluation of the transcription factors was achieved at 15, 30 and 60 dpi (n=6 for each time point). In REMI implanted animals, quantitative analysis revealed that the percentage of ATF-3 expressing DRG neurons decreased from 15 dpi (18%) to 60 dpi (7%). Similarly, cJun positive cells significantly decreased from 30 days (47.8%) to 60 days (13.4%; p< 0.005). Importantly, these results were comparable to those observed in the tube-only control subjects, suggesting the lack of exacerbation injury by micro-motion in the interfaced animals. To test further the effect of nerve stretching in REMI induced microinjuries, a separate cohort of 18 animals undergo cyclic limb stretching at full extension weekly after REMI implantation for 15, 30 and 60 days. Routine limb extension did not affect the levels of ATF-3 or cJUN observed in the DRG neurons. Together, these results indicate normal progression of nerve repair and regeneration over time despite limb movement or nerve stretching, and support the notion that the REMI forms a monolithic structure with the

nerve. These findings provide evidence of limited microinjuries by regenerative PNIs and suggest that such interfaces will be likely more stable over time.

Title: Histological comparison of acute and chronic tissue response to flexible polyimide and rigid silicon neural implants

Authors: *M. WELKENHUYSEN, A. ANDREI, O. KRYLYCHKINA, S. MUSA
BIONE, Imec, 3001, Belgium

Abstract: The sustained tissue response during chronic implantation of neural implants is considered one of the main factors preventing long-term recording of neural activity. The micromotion that induces strain between the brain tissue and the implant has been identified to play a key role in this response. Theoretical models have suggested that the induced tissue strain and hence micromotion may be significantly reduced by using flexible probes. The reduced strain would alleviate tissue encapsulation of the implant caused by the inflammatory response and increase the possibility to record chronically from nearby neurons. One way to achieve more flexible probes is to replace part of the silicon (Si) substrate used for most probes by a softer polymer such as polyimide.
We have designed and fabricated a novel hybrid neural probe consisting of a flexible polyimide shank and a rigid Si tip. The Si tip provides stability during insertion and allows integration of large electrode arrays with possibly local CMOS circuitry later on. We compared the short and long term tissue response to the hybrid probe with the response to a full Si probe with the same shank dimensions. In this randomized blinded study, 40 rats were implanted in a deep brain structure with either a 10 mm parylene-coated hybrid or Si probe. The tissue response was immunohistologically assessed after 1 and 4 weeks by the amount of inflammation, glial scarring and neuronal cell loss around the implant site at three depths; at the base, middle and tip of the shank.
During stereotactic implantation, we did not observe any buckling. When comparing the

different time points, we observed a decrease in inflammation over time at the middle of the shank of the Si probes. A decrease over time of the gliosis was also observed at the middle and tip of the Si probes. The neuronal cell loss also decreases over time at the tip of the Si probes. These results were expected and are in agreement with other studies reporting the effect of Si probes over time. For the hybrid probes, we observed an unexpected increase of neuronal cell loss over time at the base and at the tip. Most interestingly, less gliosis was observed at the middle and tip of the shank, and less neuronal cell loss occurred at the tip of the hybrid probes compared to the Si probes, but these significant differences only appeared at short term.
In conclusion, we successfully implanted a novel flexible, hybrid polyimide-Si neural probe in rats and proved that neuronal cell loss at the tip is significantly reduced compared to a full Si probe. This result suggests that the hybrid probes may be more likely to record neuronal activity at the probe tip than Si probes. However, this effect may only be short term.

Title: Quantitative evaluation of polyethylene glycol (PEG) as a therapeutic for the reactive response of brain cells in primary mixed cortical cultures

Authors: *S. SOMMAKIA[1], J. L. RICKUS[1,2,3], K. J. OTTO[1,4]
[1]Weldon Sch. of Biomed. Engin., Purdue Univ., W LAFAYETTE, IN; [2]Agr. & Biol. Engin., [3]Physiological Sensing Facility, [4]Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN

Abstract: Implantable intracortical microelectrodes have the potential to treat many neurological disorders, but are limited by a reactive response of brain tissue. This reactive response manifests in a glial scar, composed of a core of activated microglia and a sheath of reactive astrocytes, and a loss of neural density in the vicinity of the implanted electrode. The scar is accompanied by a loss of functionality, with a decrease in recordable signal quality and an increase in electrode impedance to unacceptable levels. It is thought that the initial phases of the injury response play a critical role in defining the extent of the chronic response. Polyethylene glycol (PEG) possesses antifouling and membrane sealing properties, making it an attractive therapeutic capable of

modulating protein and cell adhesion. We use an *in vitro* primary mixed cortical cell culture system to provide a controlled environment for testing PEG as a therapeutic. To simulate vascular injury and accumulation of blood borne components, we use lipopolylysaccharide (LPS), a bacterial endotoxin that activates some of the same receptors as do other proinflammatory blood proteins such as fibrinogen and thrombin. Forebrains from Day 17 embryonic rat pups were dissociated and plated in 96 well plates for 1 week, at which point segments of 50um-diameter tungsten microwire were placed atop the cultures, one microwire per well, and left to incubate with the cells for an additional 1 week. The microwires were coated with either LPS only, PEG only, a 1:1 mixture of LPS and PEG, or uncoated. The cells were then fixed with 4% paraformaldehyde, labeled with primary antibodies for Iba-1 (microglia), GFAP (astrocytes), and beta-3-tubulin (neurons), followed by the appropriate secondary antibodies and imaged. The resulting images were analyzed to obtain a cellular response index for each cell type in interface and distant regions. Our results show that microglia respond to LPS-coated microwire with an elevated response index in both the interface and distant regions, and that the addition of PEG to LPS prevents any statistically significant increase in the microglial response index compared to uncoated and PEG coated response index. In contrast, the astrocyte response index to LPS-coated and uncoated microwire in the interfacial region was not statistically different, whereas PEG-treated microwire (with and without LPS) resulted in a lower response index, indicating that astrocytes were responding to the presence of the microwire rather than the LPS treatment. Neurons exhibited a similar response index to astrocytes, indicating a preferential attachment and growth to an underlying astrocyte layer.

Title: Towards informed device design: Modeling the foreign body response to neural recording devices

Authors: *N. NOLTA, J. L. SKOUSEN, K. BOLICK, P. A. TRESCO
Bioengineering, Univ. of Utah, Salt Lake City, UT

Abstract: Recent studies have shown the potential for using implantable microelectrode arrays to provide volitional control of external devices in patients suffering from spinal cord injury. However, despite the promising potential of this technology, achieving widespread clinical application requires improving long-term recording consistency over a clinically relevant time frame. There is near consensus in the field that the foreign body response (FBR) mounted against implanted devices contributes to the observed recording instability over chronic indwelling times. While a number of commercial devices are available, none were designed using criteria derived from a study of the foreign body response that the body mounts against such devices. Our studies suggest that device surface bound macrophages and more specifically their released factors are responsible for the evolution and maintenance of the FBR. It follows then, that device surface area and geometry are major contributing factors to the overall neuro-inflammatory burden of the device and its effects on surrounding neural tissue and beyond. To validate this idea and to create a predictive tool to investigate future device designs, we have created a finite element model to predict the distribution of macrophage-released factors surrounding a number of commercially available recording devices and used histological tools to validate our predictions. Based on findings from these studies we present a number of simple design changes to traditional device architectures and geometries that our model suggests would be effective in reducing the FBR to these devices and should improve recording consistency and longevity.

Abstract: Natural control of advanced prosthetic devices demand sensitive recordings of neural activity, and while different types of neural electrode arrays have been designed, placement of multi-electrode interfaces in the residual nerve of amputees offer a natural portal to recording of

individual action potentials activated during intended limb movement. However, achieving long-term reliability of intraneural peripheral interfaces remains a formidable challenge. We developed a non-obstructive regenerative multi-electrode neural interface (REMI) that record single spike activity from amputated peripheral nerves in freely moving animal in as early as 7 days. Here we report on the histological evaluation of foreign body response to chronic implantation of the REMI electrode at 15, 30 and 60 days post-implantation, and compared it to that observed with the Utah slanted electrode array (USEA). Co-visualization of activated macrophages (ED-1) and inflammatory cytokines (TNF alpha), with myelinating Schwann cells (P0) and axons (NF200), revealed progressive nerve repair and reduction in the size of the macrophage coating of the electrodes. For both the REMI and the USEA, the electrode-nerve interface stabilized overtime with reduction in cytokine expression and cellular proliferation (Ki-67) close to the electrode-tissue interface. Using RT-PCR for 84 different genes associated with nerve function and inflammation, we confirmed that the peripheral nerve sustains significant damage during implantation of both REMI and USEA electrode arrays. However, the peripheral nerve undergoes spontaneous axonal repair, and showed progressive reduction in markers of inflammation. This cellular and molecular tissue response is contrary to increase scar formation observed in the brain after electrode insertion, and underlies the different tissue response to peripheral intraneural interfaces. No correlation was found between the inflammatory response and the signal decay observed over time in both types of electrodes. The data support the notion that cellular responses other than foreign-body reaction to the electrodes might be responsible for signal decay observed over time in intraneural peripheral nerve interfaces.

Title: Neuroprotection and antioxidant effects of a SOD mimic on neural implants

Authors: *N. R. SNYDER[1], X. T. CUI[2]
[1]Univ. of Pittsburgh, Glenshaw, PA; [2]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Within the last decade, the development of neural prosthetics through a brain tissue-electrode interface has become increasingly popular as a potentially viable method to restore lost sensory and motor function. In order for proper function of neural prosthetics, high-quality signals must be recorded. Furthermore, for human use, the quality of these signals must be reliable on the order of years to ensure proper function without the need to cause unnecessary damage to the cortex by surgically removing and inserting a new implant. Thus far, the brain tissue response to implanted electrodes has prevented reliable chronic recordings for human clinical applications. After electrode implantation, neuronal density around the implant site decreases due to both acute (initial cell death, inflammatory response) and chronic (glial scar formation and neurodegeneration) responses. To reduce local neurodegeneration at the electrode site, a synthetic manganese chelator complex was utilized that has demonstrated in vivo neuroprotective effects in the presence of oxidative stress. This complex mimics the endogenous metalloprotein superoxide dismutase (SOD) which functions as a scavenger of reactive oxygen species (ROS). To test the performance of the SOD mimic (SODm), a synthetic derivative of the compound is covalently attached to a silicon surface and tested for neuroprotective effects. To determine the radical scavenging capabilities of the immobilized SODm, a lipopolysacharide (LPS) stimulated microglial cell line was used to model inflammatory-triggered ROS production. After the cells were cultured on the SODm surface and activated with LPS, the levels of various ROS were determined using the Griess reagent assay as well as a series of synthesized fluorescent sensors specific for several oxidative species. Further evidence for the activity of the SODm is examined via a co-culture of activated microglia and primary rat neurons and the subsequent assessment of cell viability. By mitigating the effects of reactive oxygen species (ROS), we target specifically the processes that mediate the onset of neurodegeneration around implant sites. To verify the potential of the SODm for further in vivo use on neural electrodes, both in vitro ROS production, and the cell viability of neurons cultured together with activated microglia in the presence of the SODm are evaluated.

Abstract: Brain Machine Interfaces are tools for recording neural signals but they can also be used as devices to prevent symptoms from specific neurological disorders. The long-term function of these devices depends greatly on their biocompatibility and long-term stability. Studies have shown that the evoked brain tissue reaction after implantation is of importance for the gradual loss of electrode recording capacity over time. This loss of function may be due to a loss of neurons and/or an excessive astroglial sheath surrounding the implant, effectively insulating the neurons from the electrode.
In a previous study, we found that even though there was an overall decrease in neuronal density in the 0-50µm area surrounding the implant as compared to naïve rat brain tissue there were still NeuN-positive cells close to the implant. This indicates that neuron loss may not be the major factor for signal loss. The difference in the numbers of NeuN positive cells between the two time-points (6 and 12 weeks) studied was not evident in this previous study. One striking finding was that with a greater GFAP response there were significantly more NeuN-positive cells in the vicinity of the implant compared to a smaller GFAP response.
Even though our previous study clearly demonstrated that there are viable neurons within the recording distance, the question of what causes the signal degradation remains. By staining the tissue with RIP for oligodendrocytes and myelin we observed a loss of myelin in the tissue surrounding the implant. We can clearly demonstrate neurons in the area close to the implant and that should in theory allow for signal recording. The loss of electrode function, despite the close vicinity of neurons and a small GFAP response, may thus be explained by axonal damage or loss of myelin and/or comprised oligodendrocytes.
Our current working hypothesis is that the number of neurons does not vary that much over time. The gradual loss of electrode function over time may therefore be explained by demyelination and affected oligodendroglia function.

Abstract: Penetrating brain-implants, such as microelectrode arrays, alter their surrounding tissue, which in turn affects the long term functionality of these devices to record and stimulate nearby neurons.
To better understand how biological changes influence physiological recordings, we implanted microelectrode arrays under thinned-skull cranial windows in mice. Multiphoton based imaging of transgenic, fluorescent markers over time in these mice has revealed significant restructuring of tissue components local to implanted devices. Active electrode arrays were utilized, and changes in physiological recordings and electrical impedances were captured. The movement dynamics of immune cells near the implant were assessed, providing insight into the changing nature of the device/tissue interface. This research intends to characterize the impact of intracortical implants, and inform the development of strategies to maintain long-term physiological recordings from implanted microelectrodes. The ultimate goal is to help extend the reliability of such devices, and see them utilized clinically for the treatment of nervous system impairments and disorders.

Title: Permeable cytokine sinks: A new approach to passively reduce inflammation surrouding biomedical devices implanted chronically in the cns.

Authors: *J. L. SKOUSEN, P. A. TRESCO
Dept. of Bioengineering, Univ. of Utah, Salt Lake City, UT

Abstract: All chronic indwelling, biomedical devices would benefit from approaches that reduce chronic neuroinflammation at the brain tissue-device interface including hydrocephalic shunts, drug delivery systems, nerve regeneration substrates, DBS electrodes and chronic recording devices. Not only does persistent inflammation affect the funciton and viability of nearby neural cells but recent evidence suggests that it may reduce neurogenesis at more distant sites in the brain. Available evidence indicates that macrophage-secreted factors at the biotic-abiotic interface are likely responsible for the negative inflammatory sequelae. Based on this assumption and the fact that such molecules have a short biological half-life implant designs that reduce the concentration and impact of inflammatory soluble factors should reduce gliosis, BBB dysfunction, loss of neural cells and affects on neurogenesis. To explore this hypothesis, we studied the chronic brain tissue response to planar solid silicon microelectrode arrays with thick hydrogel coatings (cytokine permeability sinks) designed to passively absorb pro-inflammatory factors that are released by reactive immune cells into the device and away from adjacent brain tissue. Using quantitative immunohistochemical approaches these devices were compared to uncoated cohorts as well as arrays with a thin hydrogel coating, serving as a surface chemistry and functional sink control. After a16-week implantation period in adult Sprague-Dawley rat cortex, we observed that the incorporation of the thick permeable hydrogel was accompanied by a significant reduction in all of the classic hallmarks of the FBR including a drastic reduction in macrophage recruitment and activation, reduced neuronal cell and fiber loss, as well as reduced astrocyte hypertrophy when compared to the reaction observed surrounding either control group. The appearance of the interface was pristine and looked like the implantation tract was cut from

normal brain tissue with a hole punch with the only noticeable change being the bending of cell processes at the coating brain tissue interface. Modeling studies suggest that the thickness of the coating needs to be at least 400 microns for maximal impact. Together, the results suggest a simple, passive approach to improving the biocompatibiltiy of all types of CNS implants that are used in chronic applications.

Title: Hippocampal neurogenesis is reduced in animals with chronic peripheral nerve cuffs

Authors: *M. B. CHRISTENSEN, B. D. WINSLOW, A. E. HIGGINS, P. A. TRESCO
Bioengineering, Univ. of Utah, Salt Lake City, UT

Abstract: Recent studies have demonstrated that the administration of pro-inflammatory agents into both the central nervous system (CNS) and peripherally are sufficient to reduce neurogenesis in the dentate gyrus. Previous research from our lab has shown that persistent inflammation surrounding chronically implanted single-shank silicon microelectrode arrays, implanted in cortex above and a few millimeters anterior to the hippocampus, was sufficient to reduce neurogenesis in the dentate gyrus. Here we investigated whether persistent inflammation associated with the surface of peripheral nerve cuffs was sufficient to reduce hippocampal neurogenesis. Gold-mesh peripheral nerve cuffs were implanted around the right sciatic nerve of Fischer 344 rats for eight weeks. Non-implanted age-matched animals were used as controls. Following the implantation period, animals were transcardially perfused and the brain tissue post-fixed for 24 hours. Horizontal sections 40µm in thickness were cut using a vibratome. Every 10th section was placed in a blocking solution, consisting of 4% (v/v) donkey serum and 1.0% (v/v) Triton X-100 with 0.1% (w/v) sodium azide, overnight, incubated with antisera against DcX for immature neurons for 48 hours, rinsed, incubated in appropriate secondary antibodies for 72 hours, rinsed, then mounted on glass slides and coverslipped. Z-stack montages of the entire dentate gyrus of each brain section were obtained at 200x magnification on an Olympus FV1000 confocal microscope through the use of an automated stage. DcX+ cells were manually identified through co-localization with DAPI and the number of DcX+ neurons in the dentate gyrus was extracted from these counts. The data indicates that the number of DcX+ cells

within the dentate gyrus of animals implanted with peripheral nerve cuffs is reduced, despite their distance from the CNS and the low-level of persistent inflammation present around these devices. The findings suggest that low-levels of persistent inflammation surrounding devices away from the CNS, such as is found associated with conventional medical devices, may be sufficient to decrease the production of new neurons in the dentate gyrus.

Title: A computed tomography study of brain development in the coyote (Canis latrans).

Authors: B. A. WHITT[1], B. M. ARSZNOV[1], B. L. LUNDRIGAN[2], *S. T. SAKAI[3]
[1]Dept. of Psychology, [2]Dept. of Zoology and Michigan State Univ. Museum, [3]Dept. of Psychology and Neurosci. Program, Michigan State Univ., EAST LANSING, MI

Abstract: Previous work in the highly gregarious spotted hyena (Crocuta crocuta) revealed that both brain and skull growth occurs over a lengthy developmental period, not reaching completion until well after sexual maturity. In addition, a significant sex difference exists where adult male spotted hyenas possess more frontal cortical volume than females, reflecting differing social life histories between the sexes. It is hypothesized that social species possess larger brains and require a prolonged postnatal brain development relative to that required of solitary species. The central aim of this study was to examine total and regional brain development in one species of the highly social canid family, coyotes (Canis latrans). In order to analyze brain development in coyotes, three-dimensional virtual endocasts were created from computed tomography scans of 42 coyote skulls (23 female, 19 male) ranging in age from 1 day to 9 years. Age was either known or estimated from dentition patterns. A logistic growth curve was fit and used to determine the age for 95% asymptotic (adult) growth for total endocranial volume, skull basal length, and three brain regions (anterior cerebrum (AC), posterior cerebrum (PC), cerebellum + brainstem (CB+BS)) in 39 specimens (21 female, 18 male). The 95% of asymptotic growth for total endocranial volume and every brain region measured occurred within the juvenile life stage (12-26 weeks). An independent t-test of the residuals from linear regressions of regional brain volumes and total endocranial volume showed no significant sex differences. Similarly, no

differences were found between adults (≥93 weeks) and subadults (< 93 weeks) based on the same measures. However, a t-test of the residuals from a linear regression of total endocranial volume and skull basal length, a proxy for body size, yielded a significant difference between adults and subadults. Relative brain volume was larger in subadults than adult coyotes. This finding suggests that brain development concludes well before adult body size has been attained and contrasts with the relatively prolonged brain developmental period in the spotted hyena. The early brain development noted here parallel behavioral observations of early social development observed in coyotes in comparison to other canids. Finally, similar social life histories experienced by male and female coyotes may be reflected in the similarities in total and regional brain volumes found here.

Abstract: Variations in brain size are hypothesized to be related to multiple factors including: sociality, diet, habitat, body size, and phylogeny. Here, we sought to determine if these factors influence both total and regional brain volumes in the highly diverse carnivore family Mustelidae since variations within taxa may reveal functional features that influence encephalization separate from the broad constraints associated with comparisons made across taxa. This study used computed tomography to create three-dimensional virtual endocasts based on serial analysis of coronal sections through the adult endocranium in 11 species. Eight genera of the mustelid family were analyzed including: badgers (Taxidea taxus), grisons (Galictis vittata and Galictis cuja), fishers (Martes pennanti), american marten (Martes americana), tayras (Eira barbara), wolverines (Gulo gulo), mink (Neovison vison), honey badger (Mellivora capensis) and two river otter species (Lontra longicaudis and Lontra canadensis). A strong allometric correlation

between total endocranial volume and skull basal length, a proxy for body, size was found among mustelids. Analysis of mean residuals from linear regressions revealed that relative endocranial volume was significantly greater in aquatic compared to terrestrial mustelids. Additionally, the natatorial species possessed more neocortical surface area relative to endocranial volume than terrestrial species. These findings may be related to habitat complexity, where an aquatic habitat presents greater cognitive, spatial memory and sensorimotor challenges, such as having to navigate a complex three-dimensional environment, compared to a terrestrial habitat. These differences in the relative brain size and the relative amount of neocortex in mustelids support the notion that intrafamily comparisons may reveal family-level variation in morphological and ecological traits not detected by broader taxonomic comparative studies.

Title: Thylamys elegans: A lowly marsupial with a regal dorsal geniculate nucleus

Authors: D. SEVERIN[1], N. MADRID[1], L. OSSA-FUENTES[1], *J.-C. LETELIER[1], G. MARIN[1,2], T. VEGA-ZUÑIGA[1], J. MPODOZIS[1]

Abstract: In mammals binocular vision is dependent of the visual projections to the thalamic dorsal nucleus of the lateral geniculate (GLd). Afferences from both eyes end segregately into different layers of the GLd in an interdigitated fashion. Among eutherians, the laminar composition of the GLd is variable, and appears to be subject to phylogenetic restraints. A high degree of laminar complexity is a characteristic of the primate order only. In contrast, among metatherians this trait does not correlate simply with phylogeny. Close related species can have differences in the degree of lamination of this nucleus. Several documented cases indicate that close marsupial species that differ in visual usage also differ in GLd complexity. Members of the family Didelphidae, a clade of nocturnal American marsupials constitute a representative example of this: Didelphis virginiana, a cursorial omnivorous, exhibit a simple oligolaminar GLd structure, while Didelphis marsupialia, a cursorial predator, and Marmosa robinsoni, an arboreal

predator, both exhibit a complex multilaminar GLd. In an attempt to relate visual habits with GLd lamination we studied the visual projections in another member of the Didelphidae clade: *Thylamys elegans*, a visually active arboreal insectivorous. To this end, we performed monocular intravitreal injections of the anterograde tracer CTb, and prepared series of CTb reacted, nissl counterstained brain sections. We found that *T. elegans* features a well-developed system of visual projections, in which all major retinal targets described in mammals were easily identifiable. The suprachiasmatic nucleus, the accessory optic nuclei and the pretectal nuclei received only contralateral retinal afferences. The ventral lateral geniculate complex, the superior colliculus, and the GLd received ipsi and contralateral retinal projections. The GLd showed in its dorsal pole a striking pattern of lamination. Seven layers, latero-medially disposed were readily distinguishable. These layers displayed an alternate pattern of retinal terminals, which was complementary between the ipsi and contralateral sides. The ventral pole of the GLd does not appear to be laminated, and only at the contralateral side displayed a homogeneous plexus of labeled retinal terminals. In general, these results sustain the notion that in marsupials GLd lamination is closely related to visual usage. In particular, the results indicate that in visually active animals arboreal/predatory habits are associated with an enhanced GLd complexity, at least in the case of Didelphidae. More extensive comparative studies will be required to generalize this conclusion.

Title: Differential distribution of neurons within the neocortex of short-tailed opossums (Monodelphis domestica)

Authors: *A. M. SEELKE[1], J. C. DOOLEY[1], L. A. KRUBITZER[2]
[1]Ctr. for Neurosci., [2]Psychology, Univ. California, Davis, DAVIS, CA

Abstract: The mammalian neocortex varies along a number of dimensions including relative size, number of cortical fields, connections, and neuron number and density. These differences give rise to the variety of cognitive and behavioral specializations that different species exhibit.

Neurons are the primary unit of neural processing, and it is thought that the number, distribution and organization of neurons and synapses is related to processing capacity and cognitive abilities. Further, it is also hypothesized that the amount of area within the cortex given to processing a certain modality reflects the relative importance of that modality for species specific behaviors. For example, humans are highly visual animals, and as such a large proportion of their cortex is devoted to processing visual information.
Using isotropic fractionation, we examined the cellular composition, including neural number and density, of different areas within the neocortex of short-tailed opossums (Monodelphis domestica), a highly visual marsupial. The brains of adult opossums were dissected, isolating the neocortex. The neocortex was then further subdivided into the primary visual (V1), auditory (A1) and somatosensory (S1) areas. The tissue was homogenized and nuclei were dissociated. All nuclei were stained with DAPI and neuronal nuclei were also stained for NeuN. Nuclei were counted using standard stereological techniques, and a flow cytometer was used to determine the proportion of neuronal and non-neuronal nuclei. For each cortical region we calculated the total number of cells, total number of neurons, total cell density, neuronal density, and proportion of neurons.
The total number of cells in each primary cortical area was significantly different with A1 having the fewest number of cells and V1 having the largest number of cells. Likewise A1 also had the fewest number of neurons and V1 had the largest number of neurons. The total cell density (number of cells per mg of tissue) did not differ significantly between cortical areas. In contrast, neuronal density (number of neurons per mg of tissue) was significantly higher in A1 and S1 compared to V1. Finally, the percent of neurons was higher in A1 and S1 than in V1.
These data indicate that the opossum neocortex has a differential distribution of neurons. However, contrary to our expectations, the largest neocortical sensory region, V1, had a smaller proportion of neurons than A1 and S1. This suggests that the number and density of neurons alone may not be responsible for the increase in processing capacity, but some other factors, such as number and position of synaptic contacts and concentration of glial cells, likely contribute as well.

Title: Chemoarchitectural characterization of the tree shrew frontal cortex

Authors: *M. BOLTON[1], C. A. BAKER[1], D. FITZPATRICK[2]
[1]Disorders of Neural Circuit Function, [2]Functional Architecture and Develop. of Cerebral Cortex, Max Planck Florida Inst., Jupiter, FL

Abstract: The massive expansion of the frontal cortex of the brain during the evolution of the mammalian lineage is thought to be responsible for the increasing complexity of cognitive function and social behavior apparent in primates. Areas within primate frontal cortex have been implicated in various human psychiatric disorders but have no clear homolog in rodents. As one of the closest living relatives of primates, the northern tree shrew (Tupaia belangeri) has a highly developed cerebral cortex with somatosensory and visual systems that are well characterized, but studies on how its frontal cortex compares to that of primates and rodents remain incomplete. Here we utilize an array of cytochemical stains and molecular markers for particular neuronal subtypes to delineate particular areas within the shrew frontal cortex. We also demonstrate a dramatic expansion of the frontal cortical regions in the shrew relative to that of the mouse. The thalamic innervation and functional specialization of these areas, as well as their relation to subdivisions in rodent and primate frontal cortex, remain to be determined. The tree shrew represents a novel system for exploring the functional organization of frontal cortex and its contribution to behavior.

Title: Cytoarchitectonic characteristics of the neocortex of the gray mouse lemur (microcebus murinus).

Authors: *P. BALARAM[1], H. KENNEDY[2], J. H. KAAS[1]
[1]Psychology, Vanderbilt Univ., Nashville, TN; [2]INSERM, Bron, France

Abstract: The gray mouse lemur is a small lemuroid primate native to Madagascar that may resemble, in many ways, the ancestral primate that gave rise to divergent lemuroid, tarsoid, and anthropoid primate lineages (Le Gros Clark, 1931). Mouse lemurs share many ecological and behavioral traits with other members of the primate order, yet their brains appear much more primitive when compared to most other living primates. The neocortex of the gray mouse lemur is small, roughly 17mm from the rostral to caudal pole, and relatively smooth, with only two distinct sulci interrupting the surface. Previous histological studies have identified an average of 20 distinct neocortical areas based on the density of Nissl bodies in serial sections, yet the relative extent and location of these areas varies between accounts (Le Gros Clark, 1931; Zilles et al, 1979; Zilles and Schleicher, 1980). In order to establish a reliable cortical map that may be used to guide further anatomical studies in this species, we have reexamined the areal organization of the gray mouse lemur neocortex using modern immunocytochemical and analytical techniques. Four cortical hemispheres from two mouse lemurs were stained with a battery of known immunohistochemical markers that identify cortical areal boundaries, reconstructed in three dimensions, and differentiated into cortical areas based on changes in staining patterns across the neocortical surface. We find that the neocortex of the gray mouse lemur is indeed comprised of roughly 15-20 distinct cortical areas. The majority of the neocortical surface is occupied by primary sensory areas, with large amounts of cortical space devoted to V1, A1, and 3b. Frontal and motor areas occupy only a limited expanse of cortical surface, only extending a few millimeters caudal to the frontal pole. The areal organization of the neocortex of the gray mouse lemur suggests a more ancestral form of the primate cortex, with fewer anatomically distinct cortical areas and larger primary sensory areas in proportion to total brain volume. However, the relative locations of most cortical areas in the mouse lemur neocortex are similar to those seen in other primates and extant mammals, indicating that patterns of cortical organization are a conserved feature of mammalian evolution. Our results are presented in the form of areal maps of the neocortical surface of the gray mouse lemur brain. These architectonic maps of cortical areas generated by this study will inform further studies of cortical organization across primate species.

Title: Brain development in an insect with extensive maternal care, the tsetse fly Glossina morsitans (Diptera: Glossinidae)

Authors: *S. M. FARRIS[1], R. V. M. RIO[2]
[1]Biol., West Virginia Univ., MORGANTOWN, ; [2]Biol., West Virginia Univ., MORGANTOWN, WV

Abstract: Like birds and mammals, insects vary in the degree of maturity at birth, which is correlated with the availability of parental investment. Precocial young are born relatively independent of adult care and are mobile with well-developed sensory organs and nervous systems and external structures such as feathers, fur, and exoskeletons. In contrast, altricial young are dependent upon parents or other adults that provide food and shelter, and show reduced mobility and delays in development of the brain, sensory organs and external structures. Altricial young likely have fewer sensory and behavioral demands relative to free-living precocial young, permitting the evolution of delayed development of structures required for more independent behavior due to reduced necessity. In insects, altricial young are often observed in eusocial species such as the honey bee Apis mellifera. Honey bee larvae are contained within brood cells and are provided with food by adult nestmates. Compared with free-living larvae such as those of the fruit fly Drosophila melanogaster, sensory and integrative brain centers such as the antennal lobes and mushroom bodies show delayed development in the honey bee, first appearing at the late larval or early pupal stage rather than during embryogenesis. Delayed mushroom body development is also observed in altricial larvae of non-social species such as dung beetles, in which young develop enclosed within a food source provided by the parent. Perhaps the most extreme form of parental care in insects is adenotrophic viviparity. Obligate viviparity may be observed in the hippoboscoid flies, in which the entirety of larval development takes place within a uterus-like organ within the female in a manner similar to placental mammals. Given the strong correlation between brain development and parental care of altricial young, observed in animals across phyla, we predict that hippoboscoid larvae and pupae will display profound delays in brain development associated with the paucity of sensory and behavioral needs of a larva developing in utero. Development of the brain, with emphasis on sensory neuropils and the mushroom bodies, will be investigated in a hippoboscoid species of the family Glossinidae, the tsetse fly Glossina morsitans. We predict brain development in this species will be delayed compared to that of related flies with free-living larvae such as Drosophila melanogaster; however, due to the greater degree of maternal care and the complete lack of sensory and behavioral demands due to the restricted ecology of the larva, the delay will be far more extensive than has been observed in other altricial species.

Title: Expression of DC0 in forebrains supports genealogical correspondence of learning and memory centers across Lophotrochozoa and Ecdysozoa

Authors: *G. H. WOLFF[1], X. MA[2], N. J. STRAUSFELD[1]
[1]Dept. of Neurosci., The Univ. of Arizona, Tucson, AZ; [2]Dept. of Palaeontology, Natural History Museum, London, United Kingdom

Abstract: In arthropods, primary sensory brain neuropils project to higher order centers, such as connections from olfactory glomeruli to the mushroom bodies in insects, chelicerates, and myriapods, and from the olfactory lobes to the hemiellipsoid bodies in malacostracans. These higher centers may integrate visual, olfactory and haptic inputs, and have been described as “learning and memory” neuropils. Previously, an immunohistological study of the insect mushroom body and malacostracan crustacean hemiellipsoid body has shown that both structures express the major catalytic subunit of cAMP-dependent protein kinase A (DC0), to the exclusion of the rest of the brain, with the exception of the lower division (ellipsoid body) of the central complex, which is DC0 immunoreactive in both groups. This evidence, along with corresponding morphological elements, suggests that insect mushroom bodies and crustacean hemiellipsoid bodies are genealogically homologous, but it is unknown whether this organization is part of the ground plan for all arthropods. In order to explore homology across higher order centers in arthropods, we used immunohistochemistry methods to localize and compare DC0 expression in taxa belonging to Insecta, Crustacea, Chelicerata, and Myriapoda. We also compared these results to DC0 localization in an annelid, the polychaete worm, Nereis virens to determine whether the mushroom body ground plan may have been present in the common ancestor of Ecdysozoa and Lophotrochozoa. Despite superficial differences in morphology of higher order centers between arthropod groups, we have found DC0 expression localized to these

structures in representative taxa of Insecta, Crustacea, Chelicerata, and Myriapoda as well as in the mushroom body of the annelid, N. virens. DC0 expression has also been found in insect and crustacean central complexes, the arcuate body in chelicerates, and corresponding unpaired midline neuropils in myriapods and annelids. These studies provide further evidence for an origin of the mushroom body ground plan preceding the divergence of Lophotrochozoa and Ecdysozoa from a common ancestor, as well as correspondence of the unpaired midline neuropils. These may also serve learning and memory as well as control of multijoint appendages or, in errant annelids, segmental setae. Such findings add kindling to the debate whether a common ancestor of "Articulata" and chordates was equipped with a mushroom body-like sensory association center and a mid-line center mediating choice of behavioral actions. These considerations currently drive research into seeking corresponding patterns of protein expression in arthropod and vertebrate brains.

Title: Detection of hydrodynamic stimuli by Florida manatees (Trichechus manatus latirostris)

Authors: *R. L. REEP[1], J. C. GASPARD III[2]
[1]Univ. Florida, GAINESVILLE, FL; [2]Mote Marine Lab., Sarasota, FL

Abstract: Manatees possess a unique arrangement of specialized sensory hairs (vibrissae), present on the face and across the body. Previous research conducted on the facial vibrissae has demonstrated that touch may be the manatee's primary sensory system, highlighted by acute detection of oscillatory water movement with a particle displacement threshold as low as 1 nm and sensitive active touch discrimination (Weber fraction = 0.025). These hairs appear to be represented in the somatosensory cortex by neuronal aggregations similar to the barrels in rodents. Two Florida manatees were tested in a go/no-go paradigm to determine their abilities to detect hydrodynamic stimuli ranging from 5 - 200 Hz utilizing their post-facial vibrissae. The stimuli were generated by a sinusoidally oscillating sphere which generated a dipole field. Trials

were conducted using a staircase method and counterbalanced stimulus-present and stimulus-absent trials. Detection thresholds of the post-facial hairs were shown to be elevated in comparison to the facial vibrissae but still fairly sensitive, approaching 1 μm particle displacement for most frequencies. To further elucidate the role of the vibrissae, the manatees were trained to wear a neoprene wrap which allowed a series of isolation tests. Detection thresholds were similar at lower frequencies to the unrestricted trials even when only a small number of hairs were exposed. With over 3,000 of these tactile hairs distributed across the body, manatees may utilize their vibrissae as a sensory array, analogous to the lateral line system of a fish.

Title: Expression of developmental regulatory genes help to delineate the pallial amygdala in a lacertid lizard

Authors: E. DESFILIS[1], A. ABELLAN[2], *L. MEDINA[2]
[1]Univ. Complutense de Madrid, Madrid, Spain; [2]Univ. Lleida-IRBLLEIDA, Lleida, Spain

Abstract: The amygdala is a telencephalic center essential for control of emotions and social behavior that is present in all tetrapods. Based on the expression of developmental regulatory genes and other data, pallial and subpallial amygdalar divisions have been identified. In mammals, the pallial amygdala consists of deep nuclei, highly interconnected with the cerebral cortex and hippocampal formation, and olfactory-related superficial cortical areas. Genoarchitecture and fate mapping data in the mouse have shown that part of the mammalian pallial amygdala specifically derives from the ventral pallium, and is characterized by expression of the pan-pallial gene Tbr1 and, specifically, by Lhx9. A similar combinatorial gene expression characterizes the ventral pallial amygdala in the chicken and the anuran Xenopus laevis. However, data in reptiles are scarce and only pertain to turtles, which like birds show a diminished olfactory system. To better understand the evolution of the amygdala, we have started a research project to clone and analyze the expression of a battery of developmental regulatory genes in the embryonic forebrain of the lizard Psammodromus algirus (Reptilia,

Lacertidae), which is a sauropsid with well-developed olfactory and vomerolfactory systems. Herein we present data on the expression of Dlx2, Tbr1, Lhx2 and Lhx9 in the embryonic telencephalon of P. algirus from intermediate to late embryonic stages (S36-S40). Similarly to other vertebrates, the expression of Dlx2 and Tbr1 helps to distinguish pallial and subpallial structures of the lizard telencephalon. At S36, Dlx2 is highly expressed only in the ventricular/subventricular zone of the subpallium, but not the pallium. Nevertheless, Dlx2-expressing cells tangentially migrating from the subpallium to the pallium are observed. On the contrary, Tbr1 is expressed in all pallial derivatives and these include the primordia of lizard amygdalar structures such as the lateral and dorsolateral amygdala, the posterior dorsal ventricular ridge and nucleus sphericus. Lhx2 and Lhx9 are also expressed in these pallial amygdalar structures during development. However, the anterior dorsal ventricular ridge is free of Lhx9 expression from S37 onwards. These data help to delineate the ventral pallial amygdala of lizards and are important for trying to understand the evolution of olfactory- and association-related amygdalar areas.

Title: Quantitative analysis of canine temperament and neuroanatomical variation

Authors: *D. DAS[1,2], S. ALI[1,2,3], J. A. SERPELL[4], S. S.-H. WANG[1,2]
[1]Mol. Biol., Princeton Univ., Princeton, NJ; [2]Princeton Neurosci. Inst., Princeton, NJ; [3]Alpert Med. Sch., Brown Univ., Providence, RI; [4]Ctr. for the Interaction of Animals & Society, Univ. of Pennsylvania, Philadelphia, PA

Abstract: Dogs are the most morphologically variable of mammalian species and also show considerable breed-specific temperamental variation. We analyzed 3565 responses to the Canine Behavioral Assessment and Research Questionnaire (C-BARQ). We restricted our analysis to 63 questionnaire items representing 10 traits: Attachment or Attention-Seeking Behavior, Chasing, Dog-Directed Fear or Aggression (DFA), Excitability, Non-Social Fear (NSF), Owner-Directed

Aggression (ODA), Stranger-Directed Aggression (SDA), Stranger-Directed Fear (SDF), Separation-Related Behavior, and Trainability. Animals with health conditions expected to affect behavior were removed from the analysis.
The item-item correlation matrix showed that traits were not independent but strongly covaried. Five fear- and aggression-related traits (DFA/SDA/SDF/NSF/ODA) could be combined with Separation-Related Behavior to form a single meta-trait, Fear-Aggression-Separation (FAS). Within the FAS meta-trait, DFA, SDA and SDF also formed a more restricted meta-trait, Dog- and Stranger-Directed Fear and Aggression (DSFA) in which DFA and SDA were more closely related to one another than to SDF.
Some traits varied in close association with body size, a parameter that is associated with thyroid function. Three traits were uncorrelated with body size: Trainability, Chasing, and the metatrait of DSFA. Between pairs of breeds of similar body (and brain) size, the largest trait difference observed was up to 2.1 standard deviations (Cohen's d, using SD calculated from 2352 surveys of neutered dogs aged 2-10 years), approximately 10 times larger than differences by sex, age, or neuter status. Since dog brain volumes span an approximately 3-fold range, absolute volumes are unlikely to be a major determinant of these temperamental traits. We propose internal brain proportions ("cerebrotype"; Clark DA, Mitra PP, and Wang SS-H 2001 Nature 411:189) as a target for future neuroanatomical analysis. To this purpose we are gathering veterinary MRI scans for gross shape and volume reconstruction of identified brain structures.

Title: Ultrastructural characterization of tyrosine hydroxylase in the nucleus accumbens core and shell of the tree shrew

Authors: *L. A. MCCOLLUM[1], R. C. ROBERTS[2]
[1]Neurosci., [2]Psychiatry and Behavioral Neurobio., Univ. Alabama, Birmingham, Birmingham, AL

Abstract: Many behavioral, physiological, and anatomical studies utilize animal models to investigate human striatal pathologies. Although commonly used, rodent striatum may not

present the optimal animal model for certain preclinical studies due to a lesser morphological complexity than that of non-human primates, which are increasingly restricted in research. As an alternative, the tree shrew could provide a beneficial animal model for studies of the striatum. The gross morphology of the tree shrew striatum resembles that of the primate, with the separation of the caudate and putamen by the internal capsule. However, past research of the tree shrew has largely been limited to its well-developed visual and acoustic systems. The neurochemical anatomy of the dorsal striatum has recently been characterized, but the synaptic organization of the tree shrew ventral striatum, specifically the nucleus accumbens, has not yet been examined. The nucleus accumbens, a major region of the limbic system, plays a role in normal physiological functioning, such as drive-related behaviors and reward, as well as in addiction, and thus is an area of interest for research on human striatal pathologies. The current study uses immunohistochemistry of calbindin (to identify shell and core), and tyrosine hydroxylase to determine the ultrastructural organization of dopamine synapses in the nucleus accumbens of the tree shrew (*Tupaia glis belangeri, n*=3 animals). The distribution of these markers in the tree shrew was similar to that found in rodent and primate studies of the nucleus accumbens. The core contains dense immunoreactivity for calbindin while the shell displays weaker heterogeneous immunoreactivity for calbindin. Stereology was used to quantify the ultrastructural localization of tyrosine hydroxylase, which displays weaker immunoreactivity in the core (~15% of axon terminals forming synapses contain labeling for tyrosine hydroxylase), and denser immunoreactivity in the shell (~37% of axon terminals forming synapses contain labeling for tyrosine hydroxylase). In both shell and core, synapses with tyrosine hydroxylase-labeled axon terminals were primarily symmetric and were presynaptic most often to dendritic spines (69.8% and 54.8%, in core and shell respectively). The results from this study support that the tree shrew nucleus accumbens has similar neurochemical and structural anatomy to the primate striatum and is a potential model for studies of human striatal pathologies.

Title: Retinal ganglion cell in Japanese catshark, Scyliorhinus torazame

Authors: K. MUGURUMA[1], *N. YAMAMOTO[2]
[1]Lab. Fish Biol., Grad. Sch. Bioagr. Sci., Nagoya Univ., Nagoya, Japan; [2]Lab. Fish Biol, Grad Sch. Bioagr Sci, Nagoya Univ., Nagoya, Japan

Abstract: The retinal ganglion cells (GCs) represent the output channel from the eye, and their axons provide the only pathway from the eye to the brain. Therefore GC is thought to place a theoretical upper limit on the spatial resolving power (SRP) of the eye. Also, the distribution of GCs varies according to the lifestyle of the species. By examining these retinal features, we can gain insight into visual capabilities of the species and their relationships with the lifestyle. Additionally, in vertebrates, it is generally thought that the morphology of GCs varies according to their functions and their projection sites. Morphological classification of GCs has been well established in most vertebrates. However, there is only one detailed study in cartilaginous fishes (Stell and Witkovsky, 1973). The number of subtypes reported in that study is less than those of other vertebrates, hence there might be additional subtypes in cartilaginous fishes yet to be described. In the present study, the distribution of GCs and SRP in the Japanese catshark, *Scyliorhinus torazame* were investigated, and the morphology of GC was also examined by the retrograde labeling method with neural tracers (biotinylated dextran amine) in *S. torazame.* With Nissl-stained preparations, morphologically distinct populations of GCs (small-sized and large-sized GCs) were identified in the ganglion cell layer of *S. torazame*. These GC groups showed different spatial distribution patterns. A horizontal streak of high cell density was recognized in the dorsal retina for small-sized GCs, while two spots of high cell densities, or *area centrales*, were identified for the large-sized GCs, one in the nasal and the other in the temporal retina. The maximum predicted SRPs of three catsharks were 2.58-3.51 cells/deg and they are at the lower range of those among elasmobranchs. Based on the soma size and the dendritic morphology, retrogradely labeled GCs could be classified into five populations. Although the depths where the somata and dendrites are positioned are still unclear, the presence of additional subtypes in GCs was suggested in the present study.

Title: Modular recurrent circuits in the avian visual collopallium.

Authors: P. AHUMADA[1], S. TAPIA[1], M. FERNANDEZ[1], J. LETELIER[1], G. MARIN[1,2], *J. MPODOZIS[1]
[1]Biol., Univ. of Chile, Santiago, Chile; [2]Medicina, Univ. Finis Terrae, Santiago, Chile

Abstract: In the telencephalon of birds, the main zone receiving collothalamic afferences is a pallial region known as the nidopallium. Previous studies have defined the general pattern of thalamic-nidopallial connectivity, as well as the overall pattern of nidopallial projections. Nidopallial nuclei are known to form reciprocal, short-range projections with their overlaying mesopallial areas. Recent findings involving the Field -L (auditory nidopallium) have shown that these projections are organized as radially oriented columns, in a way that resembles the columnar intralaminar arrangement of the mammalian neocortex. We have re-examined in detail the organization of the visual nidopallium practicing small, circumscribed injections of neuronal tracers in brain slices and *in vivo*, as well as intracellular fillings in brain slices. We found that the visual nidopallium (VN) is organized in two main laminas: An internal lamina (the entopallium proper, E), in receipt of very dense, topographically organized afferences from its thalamic source, the nucleus rotundus, (Rt), and a dorsally adjacent lamina (intermediate nidopallium, NI, former entopalial "belt"), in receipt of more sparse afferences from the Rt. As in the case of the Field-L, we found that the system of reciprocal projections between the VN and the adjacent ventro lateral mesopallium (MLV) is formed by dorso-ventrally oriented, discrete columnar bundles of axons, which follow a precise topographic homotopic arrangement. VN-mesopallial projecting neurons were located mainly in the dorsal half of the E. Axonal terminals of these cells form a dense band that covers the internal-most side of the MVL. In turn, MVL cells contributing to the "columns" lie intermingled with or immediately dorsal to the field of VN terminals, and send its axons to the E and NI. Cells in the NI, but not in the E or MVL generate efferences that target several other pallial regions, such as the arcopallium and the frontal, lateral and caudal nidopallium. Based on these results we regarded the VN/MVL complex as composed of three differentiated layers: internal (thalamo-recipient, E), intermediate (efferent, NI) and external (associative, MVL). Interconnections between them may form operational modules in which cells located in homotopic positions in each layer are synaptically linked by an intralaminar local loop of recurrent axonal processes. The activity of each module would be driven by the incoming thalamic axon, and would result in a modulation of the activity of the efferent cells. Thus, if effective, the physiological operation of these proposed modules will close resembles that of the cortical columns.

Title: Vesicular Glutamate Transporter 2 (vGlut2), but not vGlut1, is present in avian pallium.

Authors: *M. FEIL[1], A. L. BODOR[1], P. V. LOVELL[2], C. V. MELLO[2], D. J. PERKEL[1]
[1]Univ. of Washington, Seattle, WA; [2]Oregon Hlth. & Sci. Univ., Portland, OR

Abstract: Vesicular Glutamate Transporters (vGluts) are proteins that package glutamate into vesicles prior to synaptic transmission. Three isoforms have been identified in mammals (vGlut1-3), with 1 and 2 showing a mostly complementary pattern of expression, and 3 co-localizing in a small number of cells with both 1 and 2. vGlut1 is mainly expressed in the cortex, hippocampus, and cerebellum while vGlut2 is expressed primarily in the thalamus, hypothalamus and brainstem. Knockout mice for the vGlut1 gene die shortly after weaning, indicating a crucial role for vGlut1 in development. Intriguingly, the avian genomes that have been sequenced contain no vGlut1 orthologs, despite the fact that lizards, a common ancestor of both mammals and birds, have orthologs of both vGlut1 and 2. The fact that birds function without vGlut1 suggests there may be an increased functional role for vGlut2 in the avian brain. Indeed, vGlut2 expression in the chicken brain is similar to the combined pattern of both vGlut1 and vGlut2 in mammals. To further demonstrate the presence and potential role of vGlut2 in avian pallial circuitry, we used immunocytochemical methods to study the brain distribution of vGlut2 protein in zebra finch, a representative avian species with well-defined neural circuitry. To confirm the specificity of antibodies to vGlut2, we first performed co-localization of anterograde tracer with vGlut2 in known glutamatergic terminals in RA that originated from the pallial song nucleus HVC. Electron microscopy further confirmed that labeling was restricted to synaptic terminals containing vesicles, and in situ hybridization was used to confirm the presence of mRNA in somata. We found that a large number of vGlut2-positive cells are present throughout the zebra finch pallium, and also found evidence for vGlut2 positive synapses in three different song nuclei (nucleus HVC, Area X, and robust nucleus of the arcopallium), which were imaged and analyzed for size, and the potential identity of post-synaptic elements. Our results are consistent with the notion that avian vGlut2 has largely taken over vGlut1 functions. This could have happened through an expansion of the vGlut2-expressing neuronal populations in the avian pallium, or by turning on vGlut2 expression in pallial cells that did not express it. We believe our study contributes important facts to the long disputed evolutionary relationship between the avian pallium and the mammalian cortex.

Title: Retinal projections in a palaeognath bird, the chilean tinamou (Nothoprocta perdicaria)

Authors: Q. KRABICHLER[1], H. LUKSCH[1], J. MPODOZIS[2], C. MORALES[2], *G. J. MARÍN[2,3]
[1]Dept. of Zoology, Technische Univ. Muenchen, Freising Weihenstephan, Germany; [2]Facultad de Ciencias, Univ. de Chile, Santiago, Chile; [3]Facultad de Medicina, Univ. Finis Terrae, Santiago, Chile

Abstract: The Tinamidae is a family comprising 47 species of birds, which forms a monophyletic group with the flightless 'Ratites'. Together they establish the avian line of the Palaeognathae. They are generally considered to be a very basal group, which segregated from the Neognathae (containing all other extant birds) very early in the evolution of birds. It is thus of interest to compare the basic neuronal circuitry of these groups to gather insights into evolutionary trends in the conservation and variations of the avian visual system.
We investigated the retinal ganglion cell layer and the retinofugal pathways in the palaeognath Chilean Tinamou, *Nothoprocta perdicaria,* by means of retinal wholemounts and injection of cholera toxin B subunit into the vitreous body of the eye of deeply anesthetised animals. As is the general pattern in birds, retinal projections were confined to the contralateral side and led to known retinorecipient regions, including the layers 2 – 7 of the Optic Tectum, the nuclei of the Lateral Geniculate Complex (nucleus geniculatus lateralis pars ventralis (GLv) and the substructures of the nucleus geniculatus lateralis pars dorsalis (GLd)), the intergeniculate leaflet (IGL), a prominent lateral anterior nucleus (LA), the pretectal nuclei (tectal grey (GT) and nucleus lentiformis mesencephali (LM)) and the nucleus of the basal optic root (nBOR). In addition, retrogradely labelled neurons were found in the nucleus isthmo-opticus (ION). The Optic Tectum showed some conspicuous differences compared to typical avian neognath model organisms such as the chicken (*Gallus gallus*) and the pigeon (*Columba livia*). Most notably, the retinorecipient layers 3 and 5 were thicker throughout their entire extent, whereas layer 4 was

substantially thinner.
Our results indicate that the retinal projections in palaeognath birds reflect an evolutionarily conserved avian pattern and show only minor differences on a macroscopic level. Future studies will determine whether this also applies to the microcircuitry in identified circuits such as the tecto-isthmic loops and the tecto-rotundal pathways.

Title: Scaling of olfactory system components across mammalian species

Authors: S. SRINIVASAN, *C. F. STEVENS
Salk Inst., La Jolla, CA

Abstract: The architecture of the olfactory system, the chemo-sensory system responsible for processing and discriminating odors, bears striking resemblance across species. This similarity naturally raises the possibility that a single theory might explain olfaction across species. As a step towards answering this question, we provide a quantitative description of two important components of the olfactory system: the glomerular layer that carries a stereotypic representation of odors, and serves as an input to the piriform cortex where much of the odor processing is thought to occur. Such a quantitative description would serve multiple purposes. First, it provides a constraint that any theory would have to satisfy. Second, it would help answer the question of whether increased odor perception arises from a greater number/density of olfactory glomeruli and/or piriform cortex neurons. We examined two species of rodents and carnivores. In these species, we estimate that each neuron in layer II averages around one synapse with each glomerulus from the bulb. This result, though surprising, becomes more clear when we consider other trends associated with brain size changes. As brain sizes increase, the number of synapses from the bulb to the piriform cortex also increases. This increase, however, is matched by a decrease in neuronal density as well as an increase in glomeruli number. Thus, the number of synapses per neuron from a glomerulus roughly stays the same.

Title: Biotin detection methods revealed novel neuronal subcellular structure in the nervous system of different vertebrate species

Authors: *A. L. BODOR[1], D. J. PERKEL[2]
[1]Otolaryngology, [2]Dept. of Biol., Univ. of Washington, Seattle, WA

Abstract: Biotin is a cofactor for several mitochondrial and other enzymes that contribute to brain energy metabolism, myelination and neurotransmitter synthesis. In the case of biotin or biotinidase deficiency, biotin holocarboxylase synthase cannot attach biotin to the enzymes that require it. Consequently mitochondrial and other carboxylase function is seriously diminished. In humans, biotin or biotinidase deficiency causes sensory, motor and cognitive symptoms and other untreatable changes as deafness, blindness and developmental delay.
The importance of biotin in the brain suggests its storage and transport in the central nervous system. Here we report a novel biotin-containing subcellular structure located in myelinated axons and dendrites of neurons of different vertebrate species. We confirmed its biotin content with two different methods: (strept)avidin-based labeling using three different chromogens (fluorophores, gold and DAB) and also an anti-biotin antibody. We named this structure a biotin body (BB). BBs are found mostly in the lower brain regions of adult zebra finch, primarily thalamus, midbrain, brainstem and cerebellum, and also in the grey matter of the spinal cord. BBs are ~200-500 nm thick, with median length 5.1µm. Electron microscopic examination revealed that BBs are formed by parallel ~5-nm thick filaments. BBs do not possess any visible membrane component. In most cases BBs contact several mitochondria. In some cases, biotin signal appears in the internal cisternae of the mitochondria juxtaposed to BBs but not in the cisternae of other mitochondria. This suggests that a biotin containing compound could be exchanged between mitochondria and BBs.
BBs in zebra finch brain are also labeled by an antibody generated against mammalian p63 protein; we have not, however, been able to confirm the identity of the antigen using western blot data.
We propose that the BB, a novel subcellular structure in neurons, contributes to the storage and distribution of biotin or biotin containing enzymes and/or represents an enzymatic hotspot

supporting mitochondrial function or localization in distant neuronal processes. Dysregulation of BBs could thus cause serious deficits in brain function.

Title: Asymmetry of insular grey matter in the chimpanzee brain and autonomic behavioral correlates.

Authors: *C. CANTALUPO[1], S. SEASE[1], W. D. HOPKINS[2]
[1]Psycholgy, Clemson Univ., Clemson, SC; [2]Georgia State Univ., Atlanta, GA

Abstract: The insular cortex in humans is known to be implicated in a very wide range of functions, from primary sensory and motor control functions, autonomic functions and emotional processing, to higher-order functions including language, attention, memory, decision making and possibly self-awareness. Much less is known about the possible functional involvement of different insular region in the great ape brain. To address this lack of data we computed left-right asymmetry measures of the anterior and posterior insular grey matter from MRI scans of a sample of 70 chimpanzee brains. Overall, we found evidence that asymmetry of the posterior insular region predicts which side of the body the chimpanzees tend to scratch when experiencing heightened arousal. In particular, we found that chimpanzees showing a rightward asymmetry of the posterior insula tended to scratch the left side of their own bodies in conditions of heightened arousal. To the best of our knowledge this is the first evidence of autonomic behavioral correlates of insular asymmetry in the chimpanzee, and the implications for theories on the evolution of insular function are discussed.

Abstract: Ongoing studies show that individual cortical areas in mouse and monkey are connected to specific sets of areas. Each connection has a specific weight and the set of connected areas and their weight values constitute the connectivity profile of the area. In both species the weights span a wide range of values (orders of magnitude, mouse: 2-3; monkey: 5-6 orders) and have a log normal distribution. The density of interareal graph in the monkey is 70% and 90% in the small mouse brain. Here we are investigating if the differences in brain size in these two species correlate with other specificities in the interareal network. Injection of retrograde tracers in a target area leads to the density of labeled neurons in source areas that fall off with distance according to an exponential distance rule that is correlated with the size of the brain in both mouse and monkey. Random networks that are constrained according to this distance rule exhibit 3-node motif distributions that are similar to those observed in the cortex, suggesting that weight-distance relationships determine the specific architectural features of the cortex.

Title: A comparative examination of biomarkers for olfactory ensheathing cells in hamsters, rabbits, pigs, non-human primates, and mice

Authors: *K. S. RAWJI[1], S. X. ZHANG[2], Y.-Y. TSAI[2], L. J. SMITHSON[1], M. D. KAWAJA[1]
[1]Ctr. for Neurosci. Studies, [2]Dept. of Biomed. and Mol. Sci., Queen's Univ., Kingston, ON, Canada

Abstract: Olfactory ensheathing cells (OECs) are the chief glial population of the mammalian olfactory nervous system, residing in the olfactory mucosa and at the surface of the olfactory bulb. We investigated the neurochemical features of OECs in a variety of mammalian species (including hamsters, rabbits, non-human primates, mice, and pigs) using three biomarkers, glial fibrillary acidic protein (GFAP), S100β, and α-smooth muscle actin (αSMA). Mucosal and bulbar OECs from all five of the aforementioned mammalian species express S100β. Mucosal OECs, but not bulbar OECs, also express GFAP in adult hamsters and non-human primates; adult mice, by comparison, have only a sparse population of OECs expressing GFAP. Both mucosal and bulbar OECs of non-human primates express αSMA; only bulbar OECs of hamsters and only mucosal OECs of rabbits express αSMA as well. Though αSMA immunostaining was not detected in the OECs of adult mice, we postulated that this structural protein may be expressed at earlier developmental periods. In adult mutant mice lacking αSMA expression, mucosal OECs displayed fewer cytoplasmic processes extending among the hundreds of olfactory axons in the olfactory nerve fascicles, and many bulbar OECs had perturbed nuclear morphology. In sum, these findings (and our previous findings in rats, guinea pigs, and cats) highlight the efficacy of S100β and αSMA as biomarkers for mammalian OECs *in vivo*. In addition, this study emphasizes the importance of empirically testing these and other

biomarkers when assessing mucosal and bulbar OECs from various mammalian species.

Title: Neuromorphology of giraffe (Giraffa camelopardalis) visual and motor cortices

Authors: T. HARLAND[1], D. KENNEDY[1], N. JOHNSON[1], B. WICINSKI[2], P. R. HOF[2], C. C. SHERWOOD[3], P. R. MANGER[4], M. SCHALL[1], *B. G. JACOBS[1]
[1]Psychology, The Colorado Col., COLORADO SPRINGS, CO; [2]Neurosci., Mount Sinai Sch. of Med., New York, NY; [3]Anthrop., The George Washington Univ., Washinton, DC, DC; [4]Anatom. Sci., Univ. of the Witwatersrand, Johannesburg, South Africa

Abstract: The morphology of neurons in the giraffe (Giraffa camelopardalis) neocortex remains largely unexplored. The present study investigates giraffe primary visual and motor cortices removed from the perfusion-fixed brains of three sub-adults and stained with a modified rapid Golgi technique. Neurons (N = 269) were quantified on a Neurolucida computer-assisted microscopy system (MBF Bioscience), which allowed examination of both dendritic and spine systems. Qualitatively, giraffe neocortex contained an array of complex spiny neurons that reflected both “typical” pyramidal neuron morphology (i.e., pyramidal neurons, n =143; magnopyramidal neurons, n = 10; Betz-like neurons, n = 6; extraverted neurons, n=35) and “atypical” spiny neurons in terms of morphology and/or orientation (i.e., horizontal pyramidal neurons, n = 17; and crab-like neurons, n = 4). In general, the neocortex appeared to exhibit a vertical columnar organization of apical dendrites. Although there was no significant difference in dendritic complexity for pyramidal neurons between primary visual (n = 78) and motor cortices (n = 65), there was a significant difference in dendritic spine density (motor cortex > visual cortex). Giraffe aspiny neurons appeared to be morphologically consistent with those of other eutherian mammals. For cross-species comparisons, giraffe pyramidal neurons were

compared to those quantified with the same methodology in elephants and cetaceans (e.g., bottlenose dolphin, minke whale, humpback whale). Across species, elephant exhibited widely bifurcating apical dendrites compared to cetaceans and giraffes. Quantitative dendritic measures (e.g., total dendritic length) showed that the elephant and humpback whale had more extensive dendrites than giraffes, whereas minke whale and bottlenose dolphin had smaller dendritic arbors. Spine measures (i.e., dendritic spine number) were highest in the giraffe, perhaps due to high quality perfusion fixation. The morphology of neurons in giraffe neocortex thus seems generally consistent with what is known about neuromorphology in cetartiodactyls.

Title: Postnatal developmental changes in excitatory and inhibitory postsynaptic protein content and the ratio of excitatory-to-inhibitory synapses in chimpanzee cerebral cortex

Authors: *T. I. DUKA[1], Z. COLLINS[1], J. GOLDSTON[1], J. L. BAKER[1], L. I. GROSSMAN[2], D. E. WILDMAN[2], W. B. BAZE[3], P. R. HOF[4], C. C. SHERWOOD[1]

Abstract: The present study continues our attempt to understand the ultrastructural and neurochemical alterations in chimpanzee cerebral cortex that accompany postnatal development.

Here, we applied morphological analysis to describe postnatal changes in the number of excitatory and inhibitory synapses across several areas of the chimpanzee cerebral cortex [the primary somatosensory (area 3b), primary motor (area 4), prefrontal (area 10), and prestriate visual cortex (area 18)] captured with transmission electron microscopy and quantitative image analysis. Using electron microscopy we found that there is an increase in the density of excitatory and inhibitory synapses in prefrontal cortex of chimpanzees between birth to 2 years of age, especially in number of asymmetric synapses. We also quantified the developmental patterns of expression for two key scaffolding proteins, the postsynaptic density (PSD) proteins PSD-95 and gephyrin. These proteins are critical for dictating the ratio of excitatory-to-inhibitory synaptic contacts. Significant changes in the
expression level of scaffolding protein PSD-95, related to excitatory,
glutamatergic transmission, were observed. The expression of PSD-95 was significantly increased in area 10 of chimpanzee during development (by 310% in the 12-24 month age group compared to the 0-12 month age group). Then, from 2 years after birth, a plateau is reached, and a steady decline in the expression level of PSD-95 occurs with age. The expression level of gypherin, associated with PSD of symmetric synapses did not appear to have significant change over the course of postnatal chimpanzee development. The differential expression of the PSD proteins at excitatory and inhibitory synapses likely accounts, at least in part, for the differences in the ultrastructural appearance of the postsynaptic densities in the two types of synapses. During chimpanzee postnatal development, marked changes in PSD-95 expression occur, presumably
reflecting changes in functional properties of excitatory networks.

Col. of Dent., New York, NY; [8]Dept. of Tourism and Conservation, Rwanda Develop. Board, Kigali, Rwanda; [9]Mountain Gorilla Vet. Program, Univ. of California Davis, Davis, CA

Abstract: Understanding the life history correlates of ontogenetic differences in the brain growth of humans and apes requires information from a diversity of hominoid species. At present, however, data on how brain size changes over the course of development are only available from chimpanzees and humans. This study describes brain growth derived from necropsy reports and measurements of endocranial volume from wild Virunga mountain gorillas. The youngest individual in our sample was an 11-day-old neonatal male with a brain mass of 208 g, which represents 42% of the adult male average. This suggests that mountain gorillas have relatively mature brains at the time of birth. Furthermore, the rate of postnatal brain growth in mountain gorillas is extraordinarily rapid, achieving maximum adult-like brain mass by two years of age. By contrast, adult brain mass in chimpanzees is not attained until age 4-5 years of age. In the skeletal sample of mountain gorillas we found that endocranial volume reaches adult size by the time of the emergence of the first permanent molars. These findings demonstrate that brain growth is accelerated in mountain gorillas in a manner that matches other life history characteristics of this species.

[1]Dept Anthropol & Sch. Biomed Sci., Kent State Univ., KENT, OH; [2]Anthrop., The George Washington Univ., Washington, D.C., DC; [3]Fishberg Dept. of Neurosci. and Friedman Brain Inst., Mount Sinai Sch. of Med., New York, NY; [4]New York Consortium in Evolutionary Primatology, New York, NY

Abstract: Neuropeptide Y (NPY) is a chemical messenger that plays a role in a variety of basic physiological functions, but has also been implicated in higher cognitive functions such as learning and memory. The density of cortical NPY-expressing axons is decreased in a variety of neuropathological processes, including depression, bipolar disorder, schizophrenia, and Alzheimer's disease, potentially contributing to the associated deficits in cognitive functions. The goal of the present analysis was to determine if there was an evolutionary shift in cortical NPY innervation in primate phylogeny. The study sample included humans, chimpanzees, gorillas, baboons, moor macaques, pigtailed macaques, capuchins, and squirrel monkeys. Stereologic methods were used to obtain the ratio of NPY axon length density to neuron density (ALv/Nv) in layers III and V/VI of cortical areas 10, 24, 44, and 22 (Tpt) and varicosity density to neuron density (Vv/Nv) in layers III and V/VI of areas 10 and 24. NPY Vv/Nv was significantly correlated with ALv/Nv in each layer and area (Pearson's r, all p's < 0.01). Among-species differences were not detected within the taxonomic groups of New World monkeys, Old World monkeys, and hominoids for any of the measures. Thus, species were collapsed into these categories for further analyses. The results of the mixed-model ANOVAs of ALv/Nv revealed significant main effects of taxonomic group and layer for each cortical area. The interaction of layer by taxonomic group was significant for all areas except 22. Post hoc analyses demonstrated that humans and great apes (hominoids) had significantly higher ALv/Nv in layers III and V/VI of area 10 and 44 relative to New and Old World monkeys. In area 24, hominoids had higher Alv/Nv in layer III. In layers V/VI, hominoids were significantly different from Old World, but not New World monkeys. In area 22, hominoids were different from New World monkeys in layer III and Old World monkeys in layers V/VI. No significant differences were detected between Old World and New World monkeys in any of the areas or layers examined here. These

results indicate that humans and great apes share a significant increase in cortical NPY innervation that is area- and layer-specific. This increase in cortical NPY innervation may contribute to the higher behavioral and cognitive flexibility observed in hominoids relative to other primates.

Abstract: The evolution in humans of an extended juvenile period, altered patterns of brain glucose utilization, neuroplasticity, and increased longevity are associated with the emergence of encephalization, but how these coevolving features are related to one another remains unclear. In the present work we focused on *GRIN3A*, a gene implicated as playing a central role both in

memory and synaptic plasticity. *GRIN3A* encodes a subunit of the NMDA receptor (NMDAR) family of glutamate-regulated ion channels. By modulating NMDAR activity *GRIN3A* may be involved in the development of dendritic spines and the evolution of human brain plasticity. *GRIN3A* is enriched in the postsynaptic plasma membrane and densities in the cerebral cortex and subcortical regions. Given the importance of postsynaptic proteins, especially the NMDA receptors, in synaptic plasticity, it is of great interest to understand the molecular evolution of the postsynaptic complex. To better understand the evolution of synaptic plasticity we performed three experiments. First, to study the molecular evolution of the NMDA receptors we examined multiple alignments of coding sequences and promoter regions to identify phylogenetically conserved and derived *cis*-regulatory elements in human, chimpanzee, gorilla, orangutan, macaque, baboon, marmoset, tarsier, and mouse lemur. We found that much of the *GRIN3A* promoter is conserved among primates, and conserved *cis*-elements include CREB- and PAX-binding sites. Moreover, conserved POU elements suggest a potential role for *GRIN3A* in dopaminergic neurons. The conservation of *cis*-elements in this gene suggests important functional constraints on the regulation of *GRIN3A* throughout primate evolution. Second, using real-time quantitative PCR we examined the expression of *GRIN3A* in different species and found a decrease in *GRIN3A* expression, which may be inversely correlated with brain size across the primate lineage. Our third experiment examined protein expression using quantitative Western blot analysis in a chimpanzee developmental series. Preliminary data suggest that chimpanzees downregulate GluN3A (NR3A) in a slightly different pattern from that seen humans. By investigating the relationship between the molecular evolution of *GRIN3A* and gene and protein expression, our results contribute to the understanding of glutamate receptor biology across the primate lineage.

Title: Organization of the chimpanzee temporal lobe: Localization of auditory core and the area MT+ complex using diffusion tensor imaging.

Authors: *K. L. BRYANT[1], D. A. GUTMAN[5,2], L. LI[6], X. ZHANG[3], T. M. PREUSS[4]
[1]Grad. Program in Neurosci., [2]Ctr. for Comprehensive Informatics, [3]Yerkes Imaging Ctr., [4]Yerkes Natl. Primate Ctr., Emory Univ., Atlanta, GA; [5]Dept. of Biomed. Informatics, Emory Sch. of Med., Atlanta, GA; [6]Dept. of Biomed. Engin., Emory Univ. and Georgia Inst. of Technol., Atlanta, GA

Abstract: Chimpanzee are the animals most closely related to humans, and therefore understanding how the two species resemble, and differ from, one another is crucial for understanding the evolutionary specializations of the brain. Chimpanzee neuroanatomy is very poorly known, however - in part because, like humans, they cannot be studied with invasive techniques. The development of noninvasive neuroimaging, and in particular diffusion-tensor imaging (DTI), which can track fiber pathways, has made direct studies of chimpanzees possible and, consequently, more detailed comparisons of humans, chimpanzees, and other nonhuman primates. The acuity of these comparisons depends on how well one can track cortical connections and localize cortical areas in chimpanzees with DTI. To evaluate the potential of DTI, we performed probabilistic tractography on in vivo chimpanzee DTI scans to localize two major cortical landmarks: 1) the auditory core, a primary sensory area with major inputs from the thalamus; and 2) the MT+ complex, a multimodal association area. Based on recent comparative myeloarchitectonic studies (Glasser et al., 2011, Soc. Neurosci. Abstr. 290.05; Hackett et al., 2001, J. Comp. Neurol. 441:197-222), we hypothesized that 1) the auditory core of the chimpanzee would be localized in Heschl's gyrus; and 2) the MT+ complex would be localized in the posterior part of the superior temporal sulcus (STS). Methods. We drew region-of-interest (ROI) masks that included the hypothesized locations of the two landmark regions on MT+ on T1-weighted images with 0.8-mm isotropic resolution. ROI masks were also drawn on known inputs to the auditory core (medial geniculate nucleus) and area MT (intraparietal sulcus (IPS), primary visual cortex (V1), and area V2. Probabilistic tractography software within FSL (www.fmrib.ox.ac.uk/fsl) was used to track cortico-cortical and subcortical connections in diffusion-weighted scans acquired with 1.8 mm isotropic resolution with 60 gradient directions and b values of 0, 1000s/mm2. Results. First, MGN projections to cortex were localized in Heschl's gyrus, indicative of the auditory core. Second, tracts from IPS and V1/V2 converged in a small gyrus buried in the posterior STS, indicative of a macaque-like position of area MT+ rather than in a human-like position, corroborating MT+ localization by Glasser and co-workers (2011). We conclude that DTI and probablistic tractography can contribute to the construction of a detailed map of chimpanzee cortical organization.

Title: Density of total cells and neurons across the cortical sheet of Old World monkeys and a chimpanzee (Pan troglodytes)

Authors: *C. E. COLLINS[1], N. A. YOUNG[1], J. H. KAAS[1], F. AWORUNSE[1], D. K. FLAHERTY[2]
[1]Dept Psychol, Vanderbilt Univ., NASHVILLE, TN; [2]Flow Cytometry Shared Resource, Vanderbilt Univ. Med. Ctr., Nashville, TN

Abstract: Previously published data from Old World baboons and macaque monkeys, a New World owl monkey and prosimian galagos illustrated a typical pattern of cell and neuron density distribution in the cerebral cortex (Collins et al., 2010b) with primary sensory areas having the highest neuron densities and of those, primary visual cortex having the highest density of neurons and total cells compared to all other cortical areas. A more than 5-fold variation in neuron density was demonstrated across the cortical expanse and significant variation was demonstrated within functional areas. In the present study, we have flattened and dissected the entire cortical sheet of a macaque monkey, a baboon and a chimpanzee and dissected each first into identifiable cortical areas, then into tiny cubes. Each tissue piece is assigned a set of coordinates on the cortical area map, weighed then homogenized into a suspension of cellular nuclei. Small aliquots from each suspension are stained for a neuron-specific marker to determine the percentage of neurons in the sample (Collins et al., 2010a). Total cell number is determined from a different aliquot from each suspension stained with the DNA stain, DAPI, and evaluated for total cells using flow cytometry (Young et al., 2012). The pattern of distribution of cell and neuron density previously described for the cortex of prosimian, New World and Old World primates appears to be conserved in the chimpanzee cortex, though the increased number of cell density transitions in the chimpanzee cortex is suggestive of an expanded number of cortical areas.

Title: Cell and neuron numbers in cortical areas of New World and Prosimian primates

Authors: *N. A. YOUNG, C. E. COLLINS, F. AWORUNSE, L. DOLL, J. KREBS, J. H. KAAS
Psychology, Vanderbilt Univ., NASHVILLE, TN

Abstract: Previous studies have reported total numbers of neuronal and non-neuronal cells for the entire cerebral cortex as a whole in non-human primates. This study was undertaken to determine if there is a predictable and non-uniform pattern of distribution in the cortical sheet of New World and Prosimian primate species. Hemispheres from squirrel monkeys (Saimiri sciureus), an owl monkey (Aotus trivirgatus) and Prosimian galagos (Otolemur garnettii) were separated from subcortical structures and the pia was removed. The sulci were opened to manually flatten the cortex. Cortical areas were accurately identified by backlighting flattened cortex using a light box to visualize densely myelinated areas. Flattened hemispheres were dissected into 5 x 5 mm pieces. Each piece was weighed and assigned to a cortical area or region. Tissue pieces were processed using the flow fractionator method to rapidly and accurately quantify the neuronal populations. Preliminary results indicate that cortical areas in New World primates differ in neuron densities and proportions of neurons. Primary visual cortex (V1) and adjoining extrastriate visual areas are the most neuron dense, followed by non-visual primary sensory areas (S1 and A1), while motor (M1) and non-primary sensory areas are the least neuron dense. These differences were more pronounced in diurnal squirrel monkeys than in nocturnal owl monkeys and galagos.

Title: NADPH-diaphorase-positive neurons in the human claustrum

Authors: L. EDELSTEIN[1], D. HINOVA-PALOVA[2], *F. J. DENARO[3], B. LANDZHOV[2], L. MALINOVA[2], M. MINKOV[2], A. PALOFF[2], W. OVTSCHAROFF[2]
[1]Medimark Corp., San Diego, CA; [2]Dept. of Anatomy, Histology and Embryology, Med. Univ. of Sofia, Sofia, Bulgaria; [3]Morgan State Univ., Baltimore, MD

Abstract: Introduction: NADPH-diaphorase (NADPHd) is a marker for neurons producing nitric oxide, somatostatin and neuropeptide Y, whose absence has been implicated as a causative agent in the excitotoxic damage prevalent in both Alzheimer's disease and Huntington's disease.
Objective: The objective of this study was to assess the distribution and morphological characteristics of NADPHd-positive cells in the human claustrum.
Sample/Methods: Samples of claustrum were obtained from the brains of two females (39 and 48 years of age) and one male (63 years of age) at autopsy. The brains did not show any overt signs of pathology or trauma. The delay from death until fixation was 6-12 hours. NADPHd histochemistry was employed, along with light and electron-microscopic analysis.
Results: NADPHd-positive neurons were irregularly distributed, often in clusters of 10 to 15. Very few positive neurons were observed adjacent to or in close proximity of the extreme and external capsules, or in the claustrum's most dorsal or caudal aspect. Reaction product diffusely filled the cytoplasm of positive neurons, while their nuclei remained stain-free. In many instances, cell staining was so intense that they resembled Golgi-impregnated neurons. These neurons were present throughout the claustrum, primarily in three sizes.
[1] Large neurons were 25-35µm in diameter, displaying multipolar, pyramidal, fusiform, elliptical, irregular, and oval soma. Each had 2-6 primary dendrites which branched into secondary and tertiary dendrites. The tertiary dendrites had an undulating course, radiating 700-900 µm from the soma. Their dendrites spread in all directions, some running parallel to the fibres of the extreme and external capsules. As a rule, they were aspiny, with the axon emanating from the perikaryon with a distinct hillock.
[2] Medium neurons were 19-25 µm in diameter, less common than the large type, and displayed round, multipolar or irregular soma, each with 3-4 dendrites with primary dendrites bifurcated or trifurcated into diverging secondary dendrites.
[3] Small neurons were 14-18 µm in diameter, with oval or elliptical soma, each with 3-4 dendrites. Primary dendrites were noted as being thin and varicose.

Conclusions: Our results provide additional insight into the distribution of NADPHd within the human claustrum. Given the critical importance of NADPHd in the context of neural transmission and its relationship to the etiology and sequelae of both Alzheimer's and Huntington's disease, it behooves us to investigate its presence in the claustrum, which has also been implicated in the development of these life-threatening disorders.

Title: Neuronal nitric oxide synthase immunoreactivity in the human claustrum: A light- and electron-microscopic investigation

Authors: *L. EDELSTEIN[1], D. HINOVA-PALOVA[2], B. LANDZHOV[2], L. MALINOVA[2], M. MINKOV[2], A. PALOFF[2], W. OVTSCHAROFF[2]
[1]Medimark Corp., San Diego, CA; [2]Dept. of Anatomy, Histology and Embryology, Med. Univ. of Sofia, Sofia, Bulgaria

Abstract: Introduction: Neuronal nitric oxide synthase (nNOS) is a relatively unique neurotransmitter which participates in many physiological and pathological processes, including the development of the nervous system and cell communication. Nevertheless, little is known about the nNOS-immunoreactive (nNOS-ir) neurons and fibers in the human claustrum, which has been the subject of growing interest from the standpoint of multisensory integration/binding, cross-modal processing and spike coincidence detection.
Objectives: The objectives of this study were to confirm the existence of nNOS-ir neurons and fibers in the human claustrum, employ light microscopy to describe their morphology and distribution, employ electron microscopy to describe and analyze their ultrastructure and synaptic architecture, verify whether they comprise a specific subpopulation of neurons, and establish whether they present with a specific pattern of organization.
Sample/Methods: Samples of claustrum were obtained from the brains of two females (39 and 48 years of age) and one male (63 years of age) at autopsy. The brains did not show any overt signs of pathology or trauma. The delay from death until fixation was 6-12 hours. Immunoreactivity to nNOS was assessed via the Avidin-Biotin Complex method.

Results: Light-microscopic analysis confirmed the presence of nNOS-ir neurons and fibers in all areas of the human claustrum, with neurons commonly found within a network of immunostained fibers. Cell bodies varied in shape and size, and were divided into three groups we've categorized as: small (35% of the sampled population, ‹19μm, but typically 13-17μm in diameter), medium (45%, 19-25μm in diameter), and large (20%, ›25μm in diameter). The density of immunostaining varied both within and between cell types, with some neurons staining more darkly or lightly than others. Electron-microscopic analysis confirmed the presence of nNOS immunoproduct within neurons, dendrites and terminal boutons, with neurons further defined by their ultrastructural features. Three types of nNOS-ir synaptic boutons were noted. Additional information will be presented.
Conclusions: There are different types of nNOS-ir neurons within the human claustrum. The large- and medium-sized cells most likely correspond with claustrocortical projection neurons, while the small-sized cells appear to be inhibitory interneurons. It is our hope that these results contribute to a better understanding of the claustrum's function in both health and disease, given its relationship with the development and sequelae of autism, schizophrenia, Alzheimer's disease, Parkinson's disease and Huntington's disease.

Title: Improved cortical myelin maps in humans, chimpanzees, and macaques allow identification of putative areal homologies

Authors: *M. F. GLASSER[1,2], T. M. PREUSS[3,4,6], G. NAIR[7], J. K. RILLING[4,8,9], X. ZHANG[5], L. LI[7], D. C. VAN ESSEN[2]

[1]Saint Louis, MO; [2]Anat. and Neurobio., Washington Univ., St. Louis, MO; [3]Div. of Neuropathology and Neurodegenerative Dis., [4]Ctr. for Translational and Social Neurosci., [5]Yerkes Imaging Ctr., Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [6]Dept. of Pathology, [7]Biomed. Imaging Technol. Ctr., [8]Dept. of Anthrop., [9]Dept. of Psychiatry and Behavioral Sci., Emory Univ., Atlanta, GA

Abstract: Cortical myelin maps based on T1w/T2w MRI images have been used previously to identify cortical areas in humans (Glasser and Van Essen 2011), chimpanzees, and macaques (Glasser et al SFN 2011). Here, we mapped the ratio of T1w/T2w in 69 humans, 29 chimpanzees, and 19 rhesus macaques to their cortical surfaces and averaged across subjects with surface-based registration. We used customizations of FreeSurfer, including species-specific templates and improvements to white and pial surface positioning, to reconstruct the cortical surfaces automatically in all three species. With these better surfaces, we generated better myelin maps in all three species than we obtained previously (Glasser et al SFN 2011). For humans and macaques, these myelin maps can be directly compared to histological cortical surface parcellations (Van Essen et al 2011a, Van Essen et al 2011b). Putative areal homologies can be identified in the intra-parietal sulcus (IPS) across the three species. In the macaque, there are three bilateral patches of heavier myelination in the IPS and parieto-occipital sulcus (POS). The anterior patch is within area 5, just posterior to area 2 on the medial bank of the IPS. The middle patch is centered on the lateral bank of the IPS and includes LIPv, LOP, and possibly VIPm. The posterior patch includes areas PO and PIP. In the chimpanzee, three bilateral patches of heavier myelination are also present in the IPS, somewhat shifted compared to the macaque. The anterior patch lies in the post central sulcus, the middle patch is near the fundus of the IPS, and the posterior patch is at the IPS/POS juncture. Human parietal cortex also has three heavily myelinated patches, but they are further shifted relative to sulcal landmarks. The anterior patch is fully in the post-central sulcus, and the middle and posterior patches are on the medial bank of the IPS. Evolutionary expansion of lightly myelinated lateral parietal cortex in humans and great apes is associated with a shift in heavily myelinated IPS regions in the three species, but these three distinct heavily myelinated patches are still identifiable and represent putative homologues. Improved myelin maps also allow better cross-species comparison of medial cortex, which has a largely similar pattern of myelin content in medial frontal, cingulate, paracentral lobular, and retrosplenial regions across species. However, the lightly myelinated region between the retrosplenial cortex and primary visual cortex is expanded in chimpanzees and humans relative to macaques. T1w/T2w MRI-based myelin maps offer a way to compare cortical architecture across species, which is helpful in understanding cortical evolution.

Title: Comparative quantitative analysis reveals preserved structural connectivity patterns in the human and macaque brain.

Authors: *A. GOULAS[1], M. BASTIANI[2,3], G. BEZGIN[4], P. STIERS[1], A. ROEBROECK[2]
[1]Maastricht Univ. Dept. of Neuropsychology and Psychopharmacology, Maastricht, Netherlands; [2]Maastricht Univ. Dept. of Cognitive Neurosci., Maastricht, Netherlands; [3]Forschungszentrum Juelich GmbH, Inst. of Neurosci. and Med. – 4, Juelich, Germany; [4]Rotman Res. Institute, Baycrest Ctr., Toronto, ON, Canada

Abstract: Decades of research on the primate brain have revealed a mosaic of distinct regions characterized by properties such as unique structural connectivity with the rest of the brain. Evidence suggests that the function of a region is constrained by its structural connections (Passingham et al., 2002). Hence, regions with similar connectivity patterns can carry out similar functions.
Since methodological and ethical issues constrain our knowledge on connectivity of the human brain, the connectivity of the macaque brain often functions as a model. However, the accuracy of the extrapolation of findings on the macaque brain to humans has been questioned since direct quantitative comparisons of the connectivity of the brain of the 2 species are scarce.
In the current study we directly compared the whole brain structural connectivity patterns of the macaque and the human brain. We used an a priori whole brain parcellation, called the Regional Map (Bezgin et al., 2012), which consists of assumed homologues in the human and the macaque brain. Information on macaque structural connectivity, as revealed through tracing studies, was extracted from the CoCoMac database (cocomac.g-node.org). Structural connectivity was estimated in 2 human subjects in vivo with diffusion imaging and probabilistic tractography. This procedure resulted in one connectivity matrix for each species describing their whole brain structural connectivity. We employed a network metric, i.e. matching index (Hilgetag et al., 2002), in order to quantify all pairwise similarities of connectivity patterns among the brain regions of each species. The similarity of the whole brain connectivity patterns was statistically significant between the species ($r=0.50$ $p<0.0001$, permutation statistics). Additional region-wise analysis revealed that the connectivity patterns of the subdivisions of the cingulate and parietal cortex were not preserved between the species ($p>0.05$, Bonferroni correction, permutation statistics). Interestingly, these subregions have been expanded during evolution (Hill et al., 2010). Moreover, cingulate subdivisions in the human brain are related to self-referential/introspective processes. Hence, the “rewiring” of these regions might be related to processes that are unique to humans.

Our approach offers rigid quantification of interspecies structural connectivity and provides new insights into connectivity changes and preservations during primate evolution.

Title: Lateralization Effects in the Human thalamus

Authors: *V. KUMAR, W. GRODD
Dept. of Psychiatry, Psychotherapy and Psychosomatics, RWTH, Univ. Clin., Aachen, Germany

Abstract: Introduction:
The thalamus acts as the central relay station of the brain and links all information from the sensory systems and the cerebellum to the cortex. However, in vivo identification of thalamic substructures are hampered by the low intrinsic tissue contrast in conventional MRI. Consequently, no valid human in vivo data exists on the variability of thalamic substructures. However, with the advent of diffusion tensor imaging (DTI) several studies (1-3) have demonstrated the ability of an anatomical parcellation. In the present study a DTI approach was used to parcellate thalamic substructures into 21 DTI clusters (3,4). Here we report on the variability of these clusters in a group of healthy subjects.
Material & Methods:
Subjects: Data were collected from 63 right-handed volunteers (32 male and 31 female) aged 20-40 years (male: 26.3 years; female: 25.5 years) were recruited. *DTI Acquisition:* 1.5 T (Siemens) EPI sequence (TR= 6700 ms; TE= 82 ms, 52 axial slices (b-value 800; 12 directions), resolution 2 x 2 x 2.5 mm. P*rocessing*: Motion correction, realignment and normalization to MNI space including b-matrix transformation. After tensor estimation each voxel was assigned to one reference direction. Volume from resulted clusters was calculated and a group statistic performed. For evaluation only clusters, greater than 60 voxels were chosen resulting in eight remaining clusters.

Results:
All 21 clusters showed a considerable individual variability in size and location. The group results in addition revealed significant hemispheric differences in five clusters # 1, 3, 6, 7, 15 accounting for ± 26 % (males) resp. ±28 % (female) differences of the whole thalamic volume
Discussion:
The hemispheric differences most probably reflect the thalamic correspondence of the structural and functional differences between both hemispheres. However, the clusters did not exhibit a clear anatomical correspondences with thalamic anatomy provided in histological atlases (6, 7). One reason might be that the available atlases do not consider the myeloarchitecture and therefore cannot reflect differences in the directionality of the underlying fiber pathways.

Title: Non-invasive three dimensional analysis of the human insula reveals a variable gyral pattern

Authors: *A. ROSEN[1,2], K. DAVIS[3,2,4], M. HODAIE[3,2]
[2]Inst. of Med. Sci., [3]Dept. of Surgery, [1]Univ. of Toronto, Toronto, ON, Canada; [4]Toronto Western Res. Inst., Toronto, ON, Canada

Abstract: Background
The detailed anatomy of the insular cortex has been difficult to study in-vivo due to its hidden location under the operculae. Prior anatomical studies have designated the presence of 6 insular gyri divided by a central insular sulcus (CIS). Since the majority of anatomical studies of the insula have been post-mortem, variation in insular anatomy has not been explored in detail. We performed cortical surface reconstruction to non-invasively assess the insula in a large group of healthy controls. The aim of the novel application of this tool was the study the precise gyral/sulcal anatomy and normal anatomical variations.
Methods
High resolution MRI images were obtained from 60 healthy subjects (33F, 27M; 38 +/- 12.8 years old) using a 3T MR axial fast spoiled gradient (FSPGR) sequence (slice thickness=1mm, slice number=160, TR=12msec, TE=5msec, 20° flip angle, matrix=256x256, FOV=24, inversion time=300msec). The University Health Network Research Ethics Board approved the procedure. FreeSurfer software (http://surfer.nmr.mgh.harvard.edu) was used to obtain pial renderings of the cortical surface of each hemisphere. The operculae were manually removed and the resulting 120 insulae were analyzed for structural integrity. The conspicuity of each of the six main gyri and the CIS were rated either “not seen,” “poorly seen” or “well seen” in each individual image.
Results
The visualization method reliably recreated the topologic structure of the insula with a high yield, allowing us to study 94% of processed images. The CIS, anterior short (ASG), anterior long (ALG) and posterior short (PSG) gyri were consistently seen in over 80% of cases. However, the accessory (AG), middle short (MSG) and posterior long (PLG) gyri were “well seen” in less than 35% of cases. Conspicuity of the MSG was greater in males than females, and in the left hemisphere compared to the right hemisphere ($p<0.05$). Within-subject analyses demonstrated increased conspicuity of the MSG in the left hemisphere compared to the right hemisphere of the same individual ($p<0.05$).
Conclusion
These data suggest that insular structures such as the CIS, ASG, ALG and PSG are consistently visualized, while others including the AG, MSG and PLG are highly variable. The anatomical variability of these insular structures provides a context to understand the diversity of functions attributed to such as pain perception, taste and viscerosensation.

Title: A comprehensive digital atlas for adult human brain: Modern neuroanatomical parcellation based on a combined cyto- and chemo-architectonic analysis

Authors: *S.-L. DING[1], J. J. ROYALL[1], B. A. C. FACER[1], S. M. SUNKIN[1], L. NG[1], A. PLAYER[2], B. R. MCMURRAY[1], P. G. LESNAR[1], C. LAU[1], D. B. SANDMAN[1], A. R. JONES[1], B. FISCHL[2], M. HAWRYLYCZ[1], E. S. LEIN[1], J. G. HOHMANN[1]
[1]Allen Inst. For Brain Sci., Seattle, WA; [2]Massachusetts Gen. Hospital; Harvard Med. Sch., Boston, MA

Abstract: A rapidly increasing number of neuroimaging studies of human brains have resulted in renewed interest in human brain anatomy and an urgent need of more precise and comprehensive human brain atlases. The few currently available human brain atlases including the widely used Brodmann's map are mainly based on classic Nissl and myelin stains, which are not precise enough to allow detailed parcellation of some brain regions (e.g., Ding et al, J Comp Neurol 514:595-623, 2009; Ding and Van Hoesen, Hum Brain Mapp 31:1359-1379, 2010). The Allen Institute for Brain Science, as part of a larger human brain mapping project, has produced a series of digital atlases of the developing human brain. In this study we have combined classic Nissl and some modern immunocytochemical (ICC) stains, as well as high-resolution imaging and informatics techniques to generate a more precise and comprehensive digital adult human brain reference atlas. MRI and DTI imaging data were obtained from the specimen, following which entire brain was sectioned coronally. Closely adjacent sections were stained for Nissl substances (200 um interval) and SMI-32 and calcium-binding proteins such as parvalbumin (400 um interval for each ICC stain). Both cortical gyri and histologically identified areas such as Brodmann's areas were included in cortical area mapping. Using a new microscopy system, the full coronal Nissl and ICC stained sections are scanned at high resolution with images clearly showing individual neurons and their dendrites and axons. Digital images of the stained sections from the entire brain including cerebral cortex, striatum, basal forebrain, amygdala, thalamus, hypothalamus, brainstem and cerebellum are annotated, with structures outlined with polygons and color-coded for easy identification of the extent of specific structures and for great usability by end-users. This reference atlas is freely accessible as part of the BrainSpan Atlas of the

Developing Human Brain, which is available via the Allen Brain Atlas data portal at www.brain-map.org or directly at www.brainspan.org. In summary, this comprehensive digital human brain reference atlas provides an important tool for medical and neuroanatomical education, comparative brain research with other species, human brain imaging studies, and diagnostic localization of brain lesions among other uses.

Title: Distribution of the 5HT2a receptor based on receptor specific antibody binding and functional distribution by agonist induced fos

Authors: R. J. FOREMAN[1], A. MITZEY[2], *M. S. BROWNFIELD[3]
[1]Comparative Biosci., [2]Biochem., Univ. of Wisconsin, Madison, WI; [3]Dept Comp Biosci., Univ. Wisconsin, MADISON, WI

Abstract: The purpose of this study was to map the distribution of the 5HT2A receptor by two methods: specific antibody binding and by specific agoninst-induced fos expression. The antibody was generated against a 5HT2a [22-41] multiple antigenic peptide and affinity purified against 5HT2a[22-41] covalently bound to an aminolink (Pierce Chemical Co.) gel column. The antibody was determined to be selective by Western blotting and its immunodistribution in our lab and by comparative immunodistribution with agonist-induced fos expression using the potent and selective 5HT2a agonist TCB-2, and by radioreceptor binding done by other labs. This antibody was also evaluated using 5HT2a knockout animals and other criteria by Weber and Andrade, 2010. Their conclusion was that our antibody is the only selective antibody available at this time.
Immuno- and agonist-induced fos localizations were determined by avidin-biotin immunocytochemistry against the receptor and against fos in the Sprague-Dawley rat cortex, thalamus, hypothalamus, caudal brainstem and spinal cord. The extensive distribution in each

study was scored by cell and fiber density and tabulated. These parallel studies showed a close correlation between immunoreactive 5HT2a cell bodies and TCB-2 induced fos expression.

Title: Neuroanatomical relationships between raphe nuclei 5-HT and relaxin-3 neurons, and promotion of arousal and social interaction via RXFP3 activation in mice

Authors: *C. M. SMITH[1], B. CHUA[1], A. BLASIAK[2], C. ZHANG[1], A. YANG[1], A. W. WALKER[1], D. E. GANELLA[1], S. LAYFIELD[1], F. SHABANPOOR[1], J. D. WADE[1], R. A. D. BATHGATE[1], A. L. GUNDLACH[1]
[1]Neuropeptides, Florey Neurosci. Inst., Melbourne, Australia; [2]Neurophysiol. and Chronobiology, Jagiellonian Univ., Krakow, Poland

Abstract: Relaxin-3 is a highly conserved neuropeptide expressed by small populations of brainstem/midbrain neurons, and which acts via its cognate G-protein coupled receptor, RXFP3. Relaxin-3-positive neurons project to RXFP3-rich regions throughout forebrain, including limbic, hypothalamic and septohippocampal circuits that control modalities such as arousal, emotion/mood, and stress responses; and the ability of relaxin-3/RXFP3 to modulate these behaviours has been demonstrated in a range of in vivo functional studies (see [1]). Here, we present findings from three experimental studies which explore the anatomy and function of relaxin-3/RXFP3 in adult male mice. Study 1: The neuroanatomical distribution of relaxin-3 immunoreactive soma and proximal processes was mapped relative to a range of neuronal markers revealing that relaxin-3-positive cell bodies/fibres in the nucleus incertus and paramedian raphe closely 'flank' more medial 5-HT neurons in the inferior dorsal raphe and median raphe, respectively. Study 2: The ability of RXFP3 activation to modulate social behaviour was tested. C57BL/6J mice were acutely injected with a selective RXFP3 agonist (RXFP3-A2, 1.0 nmol, icv) and subjected to a 3-chamber social preference test, which revealed that agonist-treated mice spent more than twice as much time interacting with novel mice than

vehicle controls (450 vs. 210 s in a 1200 s trial, $p < 0.05$, $n = 7$-10). Study 3: The effects of chronic activation of RXFP3 were assessed using a lentiviral construct that drives secretion of an RXFP3 agonist and accumulation of GFP in transduced cells. Icv infusion of this lentivirus resulted in GFP expression within cells of the choroid plexus and ventricle wall for up to 6 weeks, and mice displayed reduced habituation (i.e. prolonged high levels of locomotor activity, $p < 0.05$, $n = 12$-18) during a 30 min exposure to a novel environment 8-9 days post surgery compared to mice infused with GFP-only control lentivirus. Furthermore, local infusion into the hypothalamic paraventricular nucleus (PVN) strongly transduced cells within this region, prompting studies currently underway to investigate subsequent effects on HPA-axis and physiological stress responses. In conclusion, these studies further define the anatomy of the relaxin-3 system and demonstrate an ability of RXFP3 activation to modulate arousal and social behaviours, highlighting the potential of this signalling system as a target for therapeutic exploitation. Title: Local infusion of NMDA antagonists into prefrontal cortex rescues spatial working memory deficits in gonadectomized adult male rats

Authors: *M. N. LOCKLEAR, M. F. KRITZER
Neurobio. and Behavior, Stony Brook Univ., Stony Brook, NY

Abstract: Gonadectomy (GDX) in adult male rats significantly increases extracellular dopamine (DA) levels in the prefrontal cortex (PFC). Recent studies show that this is due in part to an exaggerated NMDA-mediated drive on the PFC pyramidal cells that project to the ventral midbrain and control firing rates of mesoprefrontal DA neurons (Aubele & Kritzer, Cerebral Cortex, 2011). The data presented here suggest that this same intracortical glutamatergic dysregulation also produces the striking deficits in DA-dependent PFC behaviors, e.g., spatial

working memory, behavioral flexibility, that are also seen in GDX rats. Specifically, we found that GDX rats' impaired performance in Barnes maze testing was rescued by bilateral intraPFC infusion of the selective NMDA antagonist APV (5µg, 15 min before the first trial). The Barnes maze is an elevated circular platform 4 ft across with 12 evenly spaced holes along its outer edge; one of the holes leads to a recessed chamber. Spatial working memory is measured in this non-rewarded task in the time it takes rats to find the secluded goal and in the number of secondary errors- repeat visits to non-goal holes, that animals make in a series of four 3 min trials (15 min inter-trial interval). We previously showed that trial-by-trial, GDX rats take significantly longer than controls (CTRL) to locate the goal and make more secondary errors and take more circuitous routes in doing so. Here we reasoned that by blocking NMDA receptors in the PFC we would lower the abnormally high PFC DA levels of GDX rats and improve their performance. This would also be expected to elevate PFC DA levels in the CTRL rats and impair their goal-finding ability. Both of these predictions were supported in our findings. For example, both GDX rats infused with APV and CTRL rats infused with saline demonstrated steep overlapping learning curves; across the four trials, latency to find goal dropped precipitously and secondary errors were few to none by the second or third trial. In comparison, the performance of CTRL rats infused with APV and GDX rats infused with saline was notably worse; these rats took significantly longer to find the goal and continued to make secondary errors on all four trials. Assessments of path and pathlength also demonstrated inefficiencies in their spatial strategies relative to CTRL and APV-treated GDX rats. These findings suggest new roles and routes whereby circulating gonadal hormones impact PFC function. These may serve as novel targets for alleviating the cognitive deficits in schizophrenia where sex differences in incidence and severity have long suggested hormone involvement (e.g, Leung and Chue et al, 2000, Acta. Psychiatr. Scand).

Title: Endocrine and functional aspects of melanin-concentrating hormone (MCH) expression during lactation

Authors: *R. D. ALVISI[1], J. C. BITTENCOURT[1], E. ZIMBERKNOPF[2], L. F. FELICIO[1]
[1]Univ. of São Paulo, São Paulo, Brazil; [2]Ctr. Universitário da Fundação de Ensino Octávio Bastos, São João da Boa Vista, Brazil

Abstract: Melanin-concentrating hormone (MCH) is a neuropeptide widely distributed in the brain of mammals, synthesized by lateral hypothalamic area (LHA) and incerto-hypothalamic area (IHy). MCH has been largely implicated in the control of food intake, body weight and energy homeostasis. Moreover lactation is an important physiological model to study hypothalamic integration to peripheral sensory signals, such as suckling stimulus and also those related to energy balance. Concentrations of mRNA for MCH increase during lactation in the medial preoptic area (MPOA) and hypothalamic anterior paraventricular nucleus, especially around the 19th day when this hormone reveals its highest peak of expression, and decrease after weaning. The physiological significance of this phenomenon is unclear. In this sense, the aim of the present study is to contribute to the investigation of sensory and endocrine factors influencing in the expression of MCH and its relationship to neuroendocrine and behavioral changes involving the end of lactation, weaning and perpetuation reproductive cycle. Wistar female rats (n= 8) were submitted to a chronic jugular vein catheterization on 13th day of lactation. Blood samples were obtained in 15, 16, 17, 18, 19, 20 and 21 days before and after suckling stimulus. Seric estrogen, progesterone, corticosterone, prolactin and MCH concentrations were measured by radioimmunoassay. Another group of subjects (n= 56), divided in subgroups of four animals, were sacrificed every day from 15th to 21st day of lactation, before and after suckling stimulus. MCH expression was evaluated in the LHA, MPOA and IHy by immunohistochemistry. On the other hand, results have confirmed that expression of MCH expression strengthens around the 19th day of lactation. This result is similar to that previously observed in Sprague-Dawley rats. The causal relation between the end of lactation and the increased expression of MCH is to be determined.

Title: Role of μ and κ opioid receptors of rostro-lateral periaquedutal gray in behavioral selection during lactation

Authors: *M. O. KLEIN[1,2], A. M. CRUZ[1], N. S. CANTERAS[3], L. F. FELICIO[1]
[1]Dept. de Patologia, Univ. De São Paulo - Faculdade De Medicina Veterinária E Zootecnia, São Paulo, Brazil; [2]Dept. de Farmacologia, [3]Dept. de Anatomia, Univ. de São Paulo - Inst. de Ciências Biomédicas, São Paulo, Brazil

Abstract: It is known that peripheral morphine disrupts maternal behavior in advance of predatory hunting and that periaqueductal gray (PAG) plays an important role in this behavioral selection. Nevertheless, the specific role for each opioid receptor in this context is to be determined. The aim of this study was to evaluate the role of μ and κ opioid receptors in behavioral selection between maternal behavior and predatory hunting. 72 Wistar female lactating rats with a guide cannula implanted in rostro-lateral PAG (rlPAG) were separated in 2 experiments with 4 groups (n=12/group) in each one: Experiment 1 - 10 nmol of μ receptor agonist, DAMGO (μ), 10nmol of κ opioid agonist, U69593 (κ), 7.91nmol of morphine sulfate (MOR) and control group (CS) which received 0.6μL of saline; Experiment 2 - 10nmol of μ receptor antagonist, CTAP plus 7.91nmol of morphine sulfate (NμM), 10nmol of κ opioid antagonist, nor-Binaltorphimine, and morphine sulfate (NκM), 7.91nmol of morphine sulfate (MOR) and control group (CS). The behavioral test was on lactation days 5 or 6. The test started 30 minutes after the drug/saline injection. Lactating females were placed in the experimental cage with their respective 8 pups and 5 cockroaches. In Experiment 1, in relation to predatory hunting, there was no difference in the number of insects captured, latency to capture each insect and no difference in the percentage of animals that captured each insect. This suggests that an acute single activation of PAG μ or κ opioid receptors does not interfere with the expression of this behavior. On the other hand, animals that received morphine injection presented an inhibition of maternal behavior. Morphine-treated animals (MOR) showed longer latencies to retrieve pups and smaller percents of animals capturing 1, 5 or 8 pups. In Experiment 2, blocking PAG μ or κ opioid receptors in the presence of morphine did not modify the morphine-induced inhibition of maternal behavior. However, the blockage of μ opioid receptor in the presence of morphine (NμM) modulated the expression of predatory hunting in morphine-treated dams. Those animals captured less insects, took longer time to catch the cockroaches and the number of animals capturing insects was decreased. Accordingly, the activation of more than one type of opioid receptor may be required to inhibit maternal behavior expression. Also, this study suggests that μ opioid receptor might play a role in expression of predatory hunting.

Title: Rapid inflow of thyroid hormone induced by visual imprinting primes later learning.

Authors: *N. AOKI[1], S. YAMAGUCHI[1], T. KITAJIMA[1], T. MATSUSHIMA[2], K. J. HOMMA[1]
[1]Pharmaceut. Sci., Teikyo Univ., Tokyo, Japan; [2]Fac. of Sci., Hokkaido Univ., Hokkaido, Japan

Abstract: Newly hatched chicks follow the first conspicuous moving object they see. This learning, called filial imprinting is restricted to a sensitive period for a few days after hatching. We have investigated determining factors for the start of the sensitive period. We have recently found that rapid inflow of the thyroid hormone 3,5,3′-triiodothyronine (T_3) accompanying imprinting training determines the opening of the sensitive period.
Intravenous injection of T_3 facilitated visual imprinting on day 1. In addition, after the sensitive period closed on day 4, chicks injected with T_3 30 min before the training became imprintable, indicating that T_3 reopened the sensitive period.
Since T_3 regulates the beginning of the sensitive period in imprinting, we examined whether injection of T_3 could extend the sensitive period of imprinting. Chicks intravenously injected with T_3 on day 1 became imprintable on day 6 or 8. This suggests once the potential of imprinting is acquired, it lasts for long period independent of visual experience. Even after the sensitive period closed on day 4, T_3 injection enabled imprinting on day 8. We call this potential given by the wave of T_3 “memory priming” (MP). Furthermore, we found the first increase in T_3 could confer MP to learning other than imprinting. That is, T_3 injection on day 1 facilitated the correct choice ratio in reinforcement learning of a color discrimination pecking task on day 4. Taken together, these data suggests once MP is conferred, the sensitive period remains open and subsequent learning can be driven. We propose that MP which originates from T_3 induced by imprinting may be followed by cascading layers of later learning.

Title: Thyroid hormone determines the start of the sensitive period of visual imprinting

Authors: *S. YAMAGUCHI[1], N. AOKI[1], T. KITAJIMA[1], T. MATSUSHIMA[2], K. J. HOMMA[1]
[1]Pharmaceut. Sci., Teikyo Univ., Tokyo, Japan; [2]Dept. of Biology, Fac. of Sci., Hokkido Univerisity, Hokkaido, Japan

Abstract: Filial imprinting in precocial birds has been studied intensively. Newly hatched chicks and ducklings follow the first conspicuous moving object they see. This is the mother under natural conditions. However, under experimental conditions it can be any other object. While following, the birds learn the color and shape of the object and become attached to it. This learning behavior, called filial imprinting, is restricted to a sensitive period which lasts only a few days in the case of chicks and ducklings. There are several theories concerning the control of the time course of this sensitive period about which very little was known, including the existence of a determining factor. Here we show for the first time that the thyroid hormone 3,5,3'-triiodothyronine (T_3) determines the opening of the sensitive period.
We attempted to identify the genes differentially expressed at an earlier phase of imprinting. Immediately after imprint training, whole brains were collected and used for cDNA microarray analysis and subjected to quantitative RT-PCR. We identified 18 genes, including Dio2, Type 2 iodothyronine deiodinase, that upregulated accompanying imprinting and its expression was enriched in brain capillaries. These results imply that Dio2 converts thyroxine (T_4) to T_3 in endothelial cells of brain capillaries and provides T_3 to brain cells for imprinting. Indeed, we found that T_3 in brain peaked around hatching, and imprinting caused an additional T_3 increase through enhanced conversion in the endothelial cells of brain capillaries, enabling imprinting via a transient non-genomic action. On the other hand, four days after hatching, T_3 levels fell to background level, at the same time that imprinting faded among dark-reared chicks. However, we found that the injecting T_3 on day 4 enabled imprinting once again. Our findings indicate that T_3 determines the start of the sensitive period of imprinting and plays a critical role in imprinting.

Title: The role of oxytocin on sodium appetite after low-sodium diet

Authors: *A. S. MECAWI, SR[1], T. VILHENA-FRANCO[1], L. MARGATHO[1], F. V. FONSECA[2], L. C. REIS[2], L. L. K. ELIAS[1], J. ANTUNES-RODRIGUES[1]
[1]Univ. of Sao Paulo, Ribeirão Preto, Brazil; [2]Dept. of Physiological Sci., Federal Rural Univ. of Rio de Janeiro, Seropédica, Brazil

Abstract: The control of water/sodium acquisition and loss is crucial for maintaining life in terrestrial environment. However, up to now, literature data on the oxytocin (OT) involvement in sodium appetite seems to be controversial. Thus, the current work has been developed aiming to investigate the changes induced by the sodium restriction diet over the oxytocinergic system, as well as the involvement of OT in the control of sodium appetite in this condition. Male Wistar rats were submitted to a normal-sodium diet (1% NaCl) or a low-sodium (NaCl < 0.1%) during four days. While on sodium restriction diet, the animals presented a significant reduction in water intake (~21%, p < 0.01), urinary sodium excretion (~83%, p < 0.01) and urinary volume (~30%, p < 0.01), associated to blood volume reduction observed by the hematocrit increasing (~8%, p < 0.05) as well as total plasma protein (~21%, p < 0.05), resulting in decrease in arterial pressure (~4%, p < 0.05) and body weight gain (~20%, p < 0.05), whereas no significant changes were observed in the plasma sodium concentration. After offering hypertonic saline (0.3 M NaCl) the sodium-restricted animals presented a significant increasing in saline intake (~190% or 3 times, p < 0.001), related to a lower increase in water ingestion (~74%, p < 0.001), which resulted in the enhance of preference for sodium (~66%, p < 0.001). We also observed a reduction in the OT plasma concentration (~38%, p < 0.05), without significant differences in the neurohypophyseal OT concentration in sodium-restricted animals. Further, animals which were on low-sodium diet presented a reduction in OT mRNA expression in the paraventricular (PVN) and supraoptic nuclei observed through real time PCR (PVN ~23% e SON ~32%, p <0,05) and in situ hybridization (PVN ~55% e SON ~33%, p

<0,05). The sodium diet restriction has induced a reduction in co-localization of Fos related antigens and OT in PVN magnocellular medial region (~50%, p < 0,05) and parvocellular posterior region (~40%, p < 0.05), demonstrating a diminution of the oxytocinergic neurons basal activity after low-sodium diet. Additionally, OT icv microinjection led to the inhibition of both hypertonic saline intake (~100%, p < 0.05) and water (~100%, p < 0.05) further to the low-sodium diet. On the other hand, it was not observed significant effect for the oxytocinergic receptor antagonist (vasotocin) over the fluids ingestion. The current data has shown that four-day-sodium-diet leads to an inhibition of OT synthesis and secretion, related to a reduction in the oxytocinergic system basal activity in both PVN and SON nucleus, which is related in its turn to the induction of sodium appetite.

Title: The effect of growth hormone on memory and gene expression in intact rats

Authors: *A. GRÖNBLADH, J. JOHANSSON, F. NYBERG, M. HALLBERG
Uppsala University, Dept Pharmaceut. Biosci., Uppsala, Sweden

Abstract: Growth hormone (GH) is a polypeptide hormone with a wide range of functions in the periphery and this hormone also has an important role in the brain. Especially the role of GH on cognition has received much attention during recent decades, demonstrating reduced cognitive capabilities in patients with growth hormone deficiency (GHD) that can be alleviated by GH replacement therapy. We have earlier demonstrated that GH in hippocampal cells may counteract apoptosis induce by opioids. In addition, GH has also been suggested to induce neurogenesis in the brain and to be involved in neuroprotection. Hence, GH has the potential of being able to improve drug-induced impairments in the brain. Anabolic androgenic steroids (AAS) are drugs known to affect the central nervous system (CNS) and has been reported to affect CNS-related behaviors such as aggression, anxiety and cognitive impairments. The aim of the present study was to examine the effects of recombinant human GH (rhGH) on memory and gene expression in several brain areas in rats pretreated with AAS. Male Wistar rats were treated with the

anabolic androgenic steroid nandrolone decanoate (15 mg/kg) or peanut oil every third day during three weeks, subsequently the rats were treated with rhGH (1.0 IU/kg) or saline daily during ten days. The Morris water maze was used to test the spatial learning and memory of the rats during the GH treatment. Quantitative real-time PCR (qPCR) was used to examine the gene expression in several brain regions, including hippocampus and hypothalamus. The results demonstrated that GH improves spatial memory in intact rats. Effects on gene expression in several brain areas were seen. In conclusion, rhGH treatment can improve memory in intact rats and the underlying mechanism may involve alterations in the GH/IGF-1 axis.

Title: Psychostimulant treatment effects on prefrontal brain activation, glutamate concentration and executive function in menopausal women with memory complaints

Authors: S. SHANMUGAN[1], R. P. R. NANGA[2], H. HARIHARAN[3], M. ELLIOTT[3], J. BRADLEY[4], C. SCHINSTINE[4], R. REDDY[3], *C. N. EPPERSON[5]
[1]Psychiatry, Univ. of Pennsylvania, Philadelphia, PA; [2]Radiology, Perelman Sch. of Medicine, Univ. of Pennsylvania, Philadelphia, PA; [3]Radiology, [4]Psychiatry, Perelman Sch. of Med. of the Univ. of Pennsylvania, Philadelphia, PA; [5]Psychiatry, Perelman Sch. of Med., Philadelphia, PA

Abstract: Background: Hypogonadal women frequently report a subjective decline in executive function. The psychostimulant lisdexamfetamine (LDX) may offset the effect of estrogen loss by enhancing dopamine and modulating glutamate function in the prefrontal cortex.
Methods: Eleven healthy menopausal women with cognitive complaints have been enrolled in this on-going, double-blind, placebo controlled, crossover study investigating the efficacy of LDX in improving executive functions, measured by self report on the Brown Attention Deficit Disorder Scale (BADDS) and performance on the continuous performance task (CPT) and N-back. A subset of women have and will undergo fMRI and ^{1}H-MRS at baseline and at the end of

each 4-week treatment arm. Left dorsal lateral prefrontal cortex (DLPFC) glutamate concentrations are measured prior to performance of the N-back task while BOLD signal is measured during task performance. All scans are conducted with a Siemens 7 Tesla whole body scanner. NIFTI brain templates are used along with MP-RAGE MRI images to aid in MRS voxel placement. Absolute glutamate concentrations are calculated from MRS data using water MRS spectra as reference using in-house developed curve fitting programs.
Results: Eight women have completed the clinical trial and three additional women have undergone baseline fMRI/^{1}H-MRS session. Baseline DLPFC glutamate levels are 8.0mM +/- 0.5mM. Fig. 1 depicts DLPFC ^{1}H-MRS data with fitted glutamate peak and fMRI data overlaid with anatomy data for the N-back task from one subject. Mean ± SD BADDS scores at Baseline and during the Placebo arm are 24.1±9.6 and 26.5±11.9, respectively. BADDS scores (18.5 ± 15.5) during the LDX treatment arm are trending lower. Likewise, there is a trend for improved performance on the CPT (p=0.08) in the LDX versus placebo condition.
Conclusions: LDX may improve subjective and objective measures of executive functioning during menopause. Multimodal brain imaging provides a more direct assessment of LDX effects in brain regions subserving executive functions.

Title: Exercise-induced hippocampal-specific activation of fatty acid synthase and accumulation of stearate is mediated by insulin receptor signaling: Impact on spatial learning and memory

Authors: *N. E. CHORNA[1,2,3], I. J. SANTOS-SOTO[1], A. VAZQUEZ-MONTES[1,3], J. L. MORALES[1], J. DE LA NUEZ[1], N. M. CARBALLEIRA[4], A. P. CHORNYY[5], S. PENA DE ORTIZ[1,2,3]

Ctr., Univ. of Puerto Rico, Rio Piedras Campus, San Juan, PR; [4]Chem., Univ. of Puerto Rico, San Juan, PR; [5]High Peformance Computing faciity, Univ. of Puerto Rico, Central Admin., San Juan, PR

Abstract: In neurons, endogenously synthesized fatty acids (FA) are esterified predominantly into phospholipids that stimulate membrane production or are used for lipid-based post-translational modification of membrane proteins. In addition, FA and their derivatives are important second messengers triggering signal transduction pathways that may result in regulation of transcription factors. Since running is known for its beneficial effects in learning and memory, we hypothesized that different life styles, voluntary exercise versus sedentariness, would differ in specific lipid-related pathways associated with improved cognition. Non-targeted neurolipidomic profiling of selective brain regions of middle-aged C57BL/6 mice identified hippocampus-specific increases in stearate, associated to voluntary exercise. Administration of streptozotocin (STZ), an established diabetogenic agent known to block insulin receptor (IR) intracellular signaling, specifically inhibited exercise-induced accumulation of stearate in the hippocampus. Accordingly, voluntary exercise induced hippocampus-specific increases in the expression of fatty acid synthase (FASN) but not elongase 1 or elongase 6 -enzymes involved in stearate biosynthesis via elongation from palmitate, an effect that was also blocked by STZ. Importantly, intracerebroventricular (i.c.v.) injections of C75, an irreversible FASN inhibitor, or STZ, where used to inhibit exercise-induced forebrain FASN activity or upregulation, respectively. Results indicate that directly blocking running associated FASN enzymatic activity with C75 or blocking its exercise-induced upregulation impairs spatial learning and memory in the Barnes Maze. Both treatment increased the escape latency, caused animals to shift from spatial to non-spatial searching strategies, and impaired spatial discrimination memory. Interestingly, in all our behavioral experiments results indicated that both C75 and STZ interfered with the exercise mediated improvements in learning and memory. Overall, these studies identified a machinery of exercise-induced hippocampal FA regulation, involving FASN and IR-mediated intracellular signaling, relevant for the beneficial effects of exercise in spatial learning and memory

Title: Adult mice maintained on a high-fat diet exhibit object location memory deficits and aberrant hippocampal gene expression

Authors: *F. D. HEYWARD[1], R. G. WALTON[2], M. S. CARLE[1], M. A. COLEMAN[1], W. T. GARVEY[2], J. D. SWEATT[1]

Abstract: Mounting evidence has established that diet-induced obesity (DIO) is associated with deficits in hippocampus-dependent memory. The bulk of research studies dealing with this topic have utilized rats fed a high-fat diet as an experimental model. To date, there has been a paucity of research studies that have established whether the memory deficits exhibited in DIO rats can be recapitulated in mice. Moreover, the majority of experiments that have evaluated memory performance in rodent models of DIO have utilized memory tests that are essentially aversive in nature (i.e., Morris water maze). The current study sought to fill an empirical void by determining if mice maintained on a high-fat diet exhibit deficits in two non-aversive memory paradigms: novel object recognition (NOR) and object location memory (OLM). Here we report that mice fed a high-fat diet over 23weeks exhibit intact NOR, albeit a marked impairment in hippocampus dependent OLM. We also determined the existence of corresponding aberrations in gene expression within the hippocampus of DIO mice. DIO mice exhibited significant reductions in both SIRT1 and PP1 mRNA within the hippocampus. Our data suggest that mice maintained on a high-fat diet present with impaired hippocampus-dependent spatial memory and a corresponding alteration in the expression of genes that have been implicated in memory consolidation.

Title: Multiparous rats: A model of better neural aging?

Authors: S. HUSBAND[1,2], F. LEMA[1], K. MONDE[1,2], J. L. GOMEZ[1,2], N. CARMONA[3], M. FRANKFURT[4], *V. N. LUINE[1,2]

Abstract: Some evidence shows that rats undergoing multiple bouts of pregnancy, birth and pup rearing (multiparous rats) show less anxiety and stress responsivity, and better cognitive function than virgin rats (nulliparous rats). However, few experiments included young rats in the studies in order to determine whether the multiparous rats age differently than nulliparous rats. We compared young virgin (2-4 mo. old), middle-aged virgin (12-15 mo. old) and middle-aged multiparous (12-15 mo. old) Fisher 344 rats for activity on the open field, anxiety on the elevated plus maze (EPM) and recognition memory (object recognition, OR and object placement OP). Young virgins were more active than middle-aged virgin and multiparous females on the open field suggesting that aging but not parity affects activity. On the EPM, no differences were found between the groups for number of open arm entries or time spent in the open arms which indicates neither age nor parity effects on anxiety. In OR memory tests with a 2h or 4 h inter-trial delay between the sample and recognition trial, no differences were found between groups which suggests that object memory is also not affected by aging or parity. In OP memory tests with a 4 h inter-trial delay, the young virgins were significantly different from the middle-aged virgins but not the multiparous females suggesting an effect of both aging and parity. Behavioral results suggest that multiple bouts of motherhood (parity) do not affect age-related decreases in overall activity. For anxiety, no age or parity effects were noted at middle-age. Likewise, object recognition was not affected by age or parity at middle-age. For spatial memory, as assessed by OP, multiparous females were not different from young virgins while the performance of middle aged-virgins was impaired suggesting that parity mitigates the effects of aging on spatial

memory. Current studies are measuring spine density in the hippocampus and medial prefrontal cortex to determine whether parity effects on memory may be related to changes in these areas. Overall, our results suggest that specific behavioral domains are affected differently by aging and by motherhood in female rats.

Title: Impairment of spatial memory by sub-chronic administration of genistein to adult male rats

Authors: *C. C. WRENN[1], M. J. BURR[2], E. R. BALL[3], B. D. WOLFE[2]
[1]Coll Pharm. & Hlth. Sci., Drake Univ., DES MOINES, IA; [2]Drake Univ., Des Moines, IA; [3]Univ. of Kansas, Kansas City, KS, KS

Abstract: Genistein is a phytoestrogen found in soy that may act as an endocrine disruptor due to its ability to bind estradiol receptors. Previous work in our laboratory has shown that when female rats consume genistein during both gestation and lactation, their male offspring have impaired spatial learning. These data suggest that genistein exerts a deleterious organizational effect on brain structures involved in spatial cognition. In the present study we tested the hypothesis that genistein also exerts an activational effect on spatial cognition by implanting genistein releasing pellets subcutaneously in adult male Long Evans rats. Pellets released genistein over a 21 day period at various doses (50, 100 and 150 mg). On the 13th day after pellet implantation, training to find a hidden platform in the Morris water maze began. Genistein had no effect on latency to find the platform across 8 days of training. A probe trial on day 9 found that rats receiving the lowest dose of genistein did not prefer to swim in the quadrant that had contained the platform during training indicating impaired memory of that location. Rats receiving the placebo pellets or the two higher doses of genistein preferred the platform quadrant. These data show that genistein impacts spatial cognition through an activational mechanism, but that the relationship between this effect and dose is non-monotonic.

Abstract: Visual influences as a mechanism of endocrine control for the metabolic, reproductive as well as adaptive abilities is necessary to respond to enviroment. This require the eyestalk neural and vascular communication. And the experimental suppression of such communication can be achieved from a few hours to several days leading many metabolic changes of the animal.

Title: 14-3-3-protein analysis of the cerebrospinal fluid in the human infant: A mass spectrometry-based feasibility study

Authors: *K. G. BROADBELT[1], E. A. HAAS[2], H. F. KROUS[2], H. C. KINNEY[3], H. STEEN[4]
[1]Dept. of Pathology and Proteomics Ctr., Children's Hosp. Boston and Harvard Med. Sch., BOSTON, MA; [2]Rady Children's Hosp. San Diego and Univ. of California, San Diego Sch. of Med., San Diego, CA; [3]Pathology, [4]Proteomics Center, Dept. of Pathology, Children's Hosp. Boston & Harvard Med. Sch., Boston, MA

Abstract: Impaired brainstem responses to homeostatic challenges during sleep are postulated to result in sleep-related sudden death of infants dying of the sudden infant death syndrome (SIDS). Our laboratory has garnered substantial evidence that a serotonergic (5-HT) disorder of regions of the medulla oblongata (lower brainstem) critical to homeostatic control is associated with a neural subset of SIDS. We have also reported that the signal transduction protein 14-3-3 family, known to play role in 5-HT regulation, is deficient in the one component of the medullary 5-HT system analyzed (gigantocellularis) with broad-based proteomics and western blotting. Ultimately we would like to determine if potentially altered cerebrospinal fluid (CSF) levels of 14-3-3 serve as a biomarker of abnormal 14-3-3 levels in the medulla of SIDS infants. As a step towards this goal, we undertook a feasibility study of the proteome in CSF obtained at autopsy in four human infants in the SIDS age range (1-5 postnatal months, median=3 months) as well as two SIDS infants (1.5-3 months, median=2.5). In the 6 cases, we applied mass-spectrometry based proteomics to: 1) create an infant postmortem CSF proteome profile; and 2) develop a targeted mass spectrometry assay to identify and quantitate the different 14-3-3 isoforms (using both spectral counting and stable isotope labeling) and confirm with western blotting. The obtained peptides were analyzed on an LTQ-Orbitrap mass spectrometer. All MS/MS data were analyzed using Protein Pilot (AB SCIEX). Protein identifications were accepted if established at greater than 50.0% probability, and if they contained at least 2 identified peptides. These values resulted in an overall peptide false discovery rate (FDR) of 1% and protein FDR of 1%. In 2 non-SIDS cases (n=2) with completed analysis to date, we identified 666 proteins in the CSF of which 46% were proteins related to cellular regulation, 19% were related to the cytoskeleton, and 11% were related to development, among other categories. We identified all but one of the 7 isoforms of the 14-3-3 family; sigma was the exception. In the single SIDS case analyzed to date we saw comparable protein number, identifying 633 proteins, and comparable assigned spectra. All 6 isoforms of the 14-3-3 proteins identified in the controls were also identified in the SIDS case. We conclude that the use of our approaches is feasible in human infant CSF at autopsy, and hold potential for the future delineation of a CSF biomarker related to 14-3-3 protein pathology in SIDS. The developmental information about the human CSF proteome in early life is of value towards understanding the role of CSF in brain function and development.

Title: Analysis of copy number variations in sudden infant death syndrome

Authors: *D. S. PATERSON[1], F. RAHIMOV[3], K. SCHMITZ ABE[3], E. A. HAAS[4], H. F. KROUS[4], H. C. KINNEY[2], K. MARKIANOS[5]
[2]Pathology, [1]Children's Hosp Boston, BOSTON, MA; [3]Dept. of Pediatrics, Havard Med. Sch., Boston, MA; [4]San Diego Sch. of Med., Rady Children's Hosp. San Diego, San Diego, CA; [5]Program in Genomics, Childrens Hosp. Bostom, Boston, MA

Abstract: The sudden infant death syndrome (SIDS) is the leading cause of postneonatal infant mortality in the United States today with an incidence of 0.57/1,000 live births. The pathogenesis of SIDS is proposed to be a multifactorial, involving a combination of environmental and genetic risk factors. While multiple environmental risk factors, including prone sleep position and maternal cigarette and alcohol use during pregnancy have been identified, genetic studies have been less successful in identifying genes associated with increased SIDS risk. In this study, we analyzed the genome of 50 Caucasian SIDS cases (36 male, 14 female) for copy number variations (CNVs) using comparative genomic hybridization (CGH) with the Agilent SurePrint G3 4x180 array in order to determine if deletions or duplications of chromosomal regions are important in SIDS. Array hybridization was successful for 49/50 SIDS cases; we identified a total of 384 CNVs (0.6% of the genome), 96 of which were unique non-overlapping CNVs. CNVs were then screened and candidates selected for further analysis. A CNV was selected if it was: 1) located in a candidate gene previously associated with SIDS; 2) a deletion(deletions are more likely to be harmful than duplications); 3) novel, i.e., not listed in the 1258 Hapmap

samples using the same CNV pipeline, the Database of Genomic Variants (DGV) and University of California Santa Cruz (UCSC) Genome Browser (previously unidentified CNVs are more likely to be specifically associated with SIDS); 4) large (over 100kb) (bigger deletions are more likely to be pathogenic); and 5) observed in multiple cases (the more cases with the CNV the greater the probability that it is associated with SIDS). Based upon these criteria, we selected 5 CNVs with copy number 0 (CNV0), representing complete deletion of the region from the genome (loss of region from both chromosomes), for further analysis, including 3 novel CNVs of 56, 121 and 147 kilobases in chromosomes 2, 4, and 6, respectively. The CNV in chromosome 6 was identified in 14/50 (28%) SIDScases. We are currently in the process of confirming the presence of these CNVs in the original cases plus an expanded cohort of 150 SIDS cases and 150 ethnicity matched controls using qPCR assays (Applied Biosystems). This study has the potential to identify novel candidate genes and pathways that may contribute to the pathogenesis of SIDS, as well as provide potential markers for use in a screening test to identify subsets of infants at increased risk of SIDS.

Title: Fetal nicotine blunts pH chemosensitivity of 5-HT neurons *in vitro* and the ventilatory response to CO2 of WT but not Lmx1b CKO mice *in vivo*

Authors: J. AVRAAM, K. L. PROCH, Y. WU, *G. B. RICHERSON
Dept Neurol, Univ. of Iowa, Iowa City, IA

Abstract: ° SIDS is linked to brainstem 5-HT abnormalities and to maternal smoking. Given that medullary 5-HT neurons are chemoreceptors and fetal nicotine exposure can impair postnatal respiratory chemoreception, it is possible that prenatal nicotine impairs the function of 5-HT neurons. An osmotic minipump that supplied 0, 6 or 60 mg/kg/day of nicotine was implanted in pregnant mice at E10 (prenatal). After pups were born, neuronal cell cultures were prepared from

the medullary raphé and fed with culture medium containing 0, 0.05 or 0.5 μM nicotine (postnatal). Neurons were placed in a recording chamber and bathed in aCSF with 5% CO_2 (pH 7.4). Patch clamp recordings were made from 5-HT neurons until firing rate (FR) stabilized at 1 Hz. They were then exposed to two episodes of 9% CO_2 (pH 7.2) each with wash out. This was repeated with aCSF containing 10 μM nicotine. Neurons exposed to prenatal nicotine, with or without postnatal nicotine, exhibited a reduced response to acidosis and to acute nicotine. At 12-21 and >22 days, neurons given the higher dose of prenatal plus postnatal nicotine had a 45% and 54% lower response to acidosis, respectively. At >22 days, the response to acute nicotine was 56% smaller. At >22 days, neurons given the lower dose of prenatal, or prenatal plus postnatal, nicotine also exhibited a significant reduction in the response to acidosis (39%) and to acute nicotine (48%). The percentage of neurons that were responsive to acidosis and acute nicotine was also significantly reduced. At 12-21 days 25% fewer neurons exposed to the higher dose of prenatal plus postnatal nicotine responded to acidosis, and at >22 days 40% fewer of these responded to acute nicotine.
° Separate experiments were performed using plethysmography on WT and $Lmx1b^{f/f/p}$ mice (which lack >99% of central 5-HT neurons) to examine the role of 5-HT neurons in mediating the effects of prenatal nicotine on the ventilatory response to CO_2. A 4 week minipump was implanted into pregnant mice at E10 supplying 60 mg/kg/day of nicotine. Litters were studied at P7, P15 and P25. Preliminary data (n=3-6 pups per group) showed that the ventilatory response to 7% CO_2 of untreated $Lmx1b^{f/f/p}$ mice was 37% of untreated WT mice at P25. At this age there was no difference in the response of untreated vs nicotine exposed $Lmx1b^{f/f/p}$ mice. However, nicotine treated WT pups had a response to 7% CO_2 that was only 15% of untreated WT pups.
° Prenatal nicotine impaired pH sensitivity of 5-HT neurons, and this may be responsible for severe blunting of chemoreception that was seen *in vivo*. These results provide a possible cellular mechanism by which maternal smoking might increase the risk of SIDS.

Title: Isoflurane eliminates serotonin (5-HT) neuron chemosensitivity *in vitro* and markedly depresses the hypercapnic ventilatory response *in vivo*.

Authors: *C. A. MASSEY, Y. WU, G. B. RICHERSON
Neurol., Univ. of Iowa, Iowa City, IA

Abstract: 5-HT neurons in the brainstem have been proposed to be central chemoreceptors, responsible for detecting hypercapnia and subsequently stimulating respiratory areas to properly maintain pH homeostasis. However, there have been inconsistent results when studies have examined the response of 5-HT neurons to increases in CO2 in vivo. Some of these studies utilized inhalational anesthetics, including isoflurane and halothane, which are potent agonists for 2-pore domain K+ (TASK) leak channels. 5-HT neurons have one of the highest levels of TASK channel expression, thus making them prime targets for these anesthetics. Here we used perforated patch-clamp recordings from cultured medullary ePet1-YFP mouse neurons (n=8) and found that isoflurane nearly completely silenced the baseline firing of 5-HT neurons in vitro and also abolished their chemosensitivity. On average 5-HT neurons tripled their firing rate in isocapnic acidosis (0.47 Hz in pH 7.4 to 1.51 Hz in pH 7.15). In isoflurane, baseline firing dropped to 0.01 Hz, and in response to acidosis increased to only 0.11 Hz (pH 7.15). Both of these effects occurred rapidly, and reversed with washout of isoflurane. Furthermore, using whole animal plethysmography we found that isoflurane markedly decreased the hypercapnic ventilatory response (HCVR) in vivo by 75% (n=4). Minute ventilation (Ve) in male wildtype (WT) C57/Bl6 mice increased by 400% (from 2.36 ml g-1 min-1 to 12.54 ml g-1 min-1) in 21% O2, 7% CO2, balance N2; in 1% isoflurane the response was reduced, as Ve increased by only 100% (from 2.48 ml g-1 min-1 to only 5.01 ml g-1 min-1). In order to isolate the effects of isoflurane on central chemoreception, we first examined the HCVR in 50% O2 to silence peripheral chemoreceptors in male WT C57/Bl6 mice. Our preliminary data (n=3) showed that Ve in these mice increased by 275% (from 3.13 ml g-1 min-1 to 11.88 ml g-1 min-1) when CO2 was increased from 0% to 7%. In 50% O2, 1% isoflurane severely reduced the HCVR in these mice, as Ve increased by only 40% when CO2 increased from 0% to 7% (from 2.21 ml g-1 min-1 to 3.16 ml g-1 min-1). These preliminary results indicate that isoflurane silences 5-HT neurons, blocks 5-HT neuron chemosensitivity, and severely blunts respiratory chemoreception, preventing any conclusions about chemoreceptors from experiments using this anesthetic. These data also support the conclusion that 5-HT neurons are central pH/CO2 chemoreceptors.

Title: Prenatal nicotine exposure reduces the activity of Raphe Obscurus neurons from P3 mice.

Authors: *V. CERPA[1,2], E. BRAVO[2], G. B. RICHERSON[1,3], J. EUGENIN[2]
[1]Neurol., Univ. of Iowa, Iowa City, IA; [2]Univ. de Santiago de Chile, Santiago, Chile; [3]VAMC, West Heaven, CT

Abstract: Mouse neonates prenatally exposed to nicotine show hypoventilation and reduced response to CO2 in vivo. In addition, isolated brainstem-spinal cord preparations from nicotine exposed P3 mice show reduced respiratory responses to acidosis and respiratory cycles shorter and more irregular than those observed in controls. Since raphe neurons contribute to the respiratory chemosensory drive, we studied whether they are involved in prenatal nicotine induced effects on respiratory rhythm.
Osmotic minipumps were implanted subcutaneously into pregnant mice (1-5 days CF1) to deliver nicotine ditartrate 60 mg Kg-1 day-1 until the end of gestation. We studied electrophysiological properties and the response to CO2 of Raphe Obscurus (ROb) neurons using whole-cell patch-clamp recording in slices from P3 control and nicotine-exposed mice. Immunohistochemistry, to detect co-expression of tryptophan hydroxylase (TpH, serotoninergic marker) and c-fos protein (neuronal activity marker), as well as immunofluorescence to detect 5-HT1A receptors were done.
The rostral part of ROb from nicotine-exposed mice presented lesser TpH+ neurons than controls (35.1 ± 2 and 41.6 ± 6, respectively; $p < 0,05$, ANOVA, post test Bonferroni). Also, TpH+ and TpH- neurons expressed less c-Fos than controls, suggesting they were hypoactives in basal conditions. This hypoactivity was confirmed in slice recordings, in which ROb neurons of nicotine-exposed mice showed reduced firing rate under basal conditions in presence or absence of glutamatergic or gabaergic synaptic currents ($p < 0.05$ and $p < 0.01$, respectively, Mann-Whitney U Test). No other differences were detected in the electrophysiological properties (Vm, RI, AHP, Cm) or in response to CO2. In addition, 5-HT1A receptors were over-expressed in ROb of nicotine-exposed mice.
In conclusion, our results show that perinatal nicotine exposure reduced the number and activity of ROb neurons at P3. Hypoactivity could be explained by an over expression of 5-HT1A autoreceptors. These findings have relevant implications for the understanding of the mechanisms underlying nicotine-induced deficit in respiration due to the key role that the raphe nuclei play in respiratory drive, chemoreception and generation of respiratory output.

Title: Intermittent hypercapnia enhances ventilatory CO2/PH chemosensitivity to overcome serotonergic dysfunction

Authors: *B. MOSHER[1], M. B. HARRIS[2]
[1]Biol. & Wildlife, [2]Inst. of Arctic Biol., Univ. of Alaska Fairbanks, Fairbanks, AK

Abstract: Serotonergic dysfunction is thought to enhance vulnerability to Sudden Infant Death Syndrome (SIDS) by compromising critical homeostatic reflexes such as ventilatory CO_2/pH chemosensitivity. We test the hypothesis that exposure to mild intermittent hypercapnia (IHc) during postnatal development will enhance chemosensitivity to overcome consequences of serotonergic deficit. Rat pups were exposed to IHc (9 consecutive cycles of 5 min 5% CO_2 in air, followed by 10 min air; constant air control) each day for 5 days beginning at postnatal day P12, and were subsequently assessed for CO_2/pH chemosensitivity using an unanesthetized juvenile rat *in situ* perfused decerebrate brainstem preparation. Chemosensitivity in the air control group was abolished by antagonism of 5-HT_{2A} receptors, confirming our previous observation that this sensitivity is critically dependent on 5-HT_{2A} receptor-mediated mechanisms. Chemosensitivity was greatly enhanced by IHc. Enhanced sensitivity was attenuated by 5-HT_{2A} receptor antagonism, but residual sensitivity was comparable to that of untreated air controls. These data demonstrate that IHc enhances a non-5-HT_{2A} receptor mediated processes capable of maintaining chemosensitivity under conditions of serotonergic dysfunction normally abolishing such sensitivity. We have proposed a “push-pull” model of raphé contributions to central chemosensitivity involving both 5HT and γ-aminobutyric acid (GABA) synthesizing neurons. We postulate that IHc enhances GABA neuron contributions resulting in preserved chemosensitivity when 5-HT neuron contributions are compromised.

Title: Probing a local chemosensory network in the medullary raphé

Authors: *M. B. HARRIS[1,2], K. E. ICEMAN[1], T. E. DICK[3], D. M. BAEKEY[4]
[1]Dept Biol. and Wildlife, Univ. Alaska Fairbanks, FAIRBANKS, AK; [2]Inst. of Arctic Biol., Univ. of Alaska Fairbanks, Fairbanks, AK; [3]Div. of Pulmonary, Critical Care and Sleep Medicine, Dept. of Med., Case Western Reserve Univ., Cleveland, OH; [4]Dept. of Physiological Sci., Univ. of Florida, Gainesville, FL

Abstract: The modulation of respiratory activity in the brainstem is, at least in part, dependent on the medullary raphé. The organization of raphe circuitry involved has not yet been described. We have previously confirmed the presence of CO2/acidosis-stimulated serotonin synthesizing (5-HT) neurons, and CO2/acidosis inhibited γ-aminobutyric acid (GABA) synthesizing neurons within the rat medullary raphé. Recently, we have identified an additional population of raphé CO2/acidosis-stimulated cells we are terming “raphé chemosensory amplifier” (RCA) interneurons. We hypothesize that raphé chemosensitivity is due to, or enhanced by, an intra-raphé network where RCA neurons receive input from both serotonergic and GABAergic neurons creating a “push-pull network” underlying raphé contributions to central chemosensitivity. To determine the relationships of the identified populations, multiple individual raphé neurons were recorded in the in situ perfused rat preparation, characterized with respect to phrenic and/or vagal activity, and further through responses to 4% hypercapnic challenges. We have simultaneously recorded representatives of each using a 16 channel multielectrode extracellular array with independent depth adjustments to allow maximal yield of individual neurons. Preliminary results illustrate relationships during baseline conditions, changes in individual neuron firing frequency and variability while altering chemosensory drive, and coordinated changes among the populations during hypercapnic stimulation. The results support our push-pull network model of chemosensory influence in the medullary raphé.

Title: Influence of isoflurane on CO_2 sensitive and insensitive raphé neurons

Authors: *S. L. JOHANSEN[1], K. E. ICEMAN[1], G. B. RICHERSON[3], M. B. HARRIS[2]
[1]Biol. & Wildlife, [2]Inst. of Arctic Biol., Univ. of Alaska Fairbanks, Fairbanks, AK; [3]Neurol., Univ. of Iowa, Iowa City, IA

Abstract: Raphé neurons contribute to the hypercapnic ventilatory response, but their identity as central chemoreceptors is debated. *In vitro* raphé serotonin (5-HT) and ɣ-aminobutyric acid (GABA) synthesizing neurons are activated and inhibited by CO_2/acidosis, respectively. We have previously demonstrated that in the unanesthetized juvenile rat *in situ* perfused decerebrate brainstem preparation these neurons are similarly chemosensitive. Studies conducted using anesthetized rats *in vivo* have not illustrated these chemosensitive neuron types. We test the hypothesis that chemosensitivity of 5-HT and/or GABA raphé neurons is masked by the anesthetic isoflurane. To determine the impact of isoflurane on neuron chemosensitivity, raphé extracellular recordings were made in the unanesthetized *in situ* brainstem preparation during a 4% hypercapnic challenge, both before and during exposure to isoflurane. Juxtacellular labeling and subsequent immunohistochemistry identified neurotransmitter phenotypes of electrophysiologically characterized neurons. Results indicate that 5-HT neurons either lose chemosensitivity or are silenced when exposed to isoflurane, in a dose dependent manner. We conclude that chemosensitive raphé 5-HT neurons identified *in vitro* and *in situ* are masked by isoflurane and potentially other anesthetics *in vivo*.

Title: Identifying a medullary "raphé chemosensory amplifier" (RCA) neuron mediated by serotonin and GABA *in situ*

Authors: *K. E. ICEMAN[1], H. M. TALLAN[1], M. B. HARRIS[2]
[1]Biol. and Wildlife, [2]Inst. of Arctic Biol., Univ. of Alaska Fairbanks, Fairbanks, AK

Abstract: Neurons within the rat medullary raphé are intrinsically sensitive to CO_2/pH change *in vitro*. Serotonin synthesizing (5-HT) neurons are activated by CO_2/acidosis, while γ-aminobutyric acid (GABA) synthesizing neurons are inhibited. We have previously demonstrated that these neurons are similarly chemosensitive *in situ.* Here we hypothesize that a previously uncharacterized pool of raphé interneurons also exhibit chemosensitivity, and that sensitivity of these medullary "raphé chemosensory amplifier" (RCA) interneurons is due to intra-raphé network input from 5-HT and GABAergic neurons in an intact system. We use extracellular recording of individual raphé neurons in the unanesthetized juvenile rat *in situ* perfused decerebrate brainstem preparation to assess chemosensitivity of putative RCA neurons before and after pharmacological antagonism of 5-HT_{2A} and $GABA_A$ receptors. We show that CO_2-stimulated RCA neurons are present in the medullary raphé and that antagonism of $GABA_A$ receptors abrogates RCA neuron chemosensitivity. Blockade of $GABA_A$ receptors increases RCA neuron baseline firing indicating removal of tonic inhibitory input from GABA neurons. In contrast, blockade of 5-HT_{2A} receptors decreases RCA neuron baseline firing, suggesting removal of tonic excitatory input from 5-HT neurons. Results demonstrate that $GABA_A$ receptor-mediated input is necessary for RCA neuron chemosensitivity and 5-HT_{2A} receptor-mediated input is necessary for RCA tonic drive. Juxtacellular labeling and immunohistochemistry indicate that RCA cells are not serotonergic, but are closely apposed to 5-HT and GABAergic neurons. Results support our "push-pull network" model of raphé contributions to central chemosensitivity. Thus, we have characterized a new type of CO_2–stimulated medullary raphé neuron, the RCA interneuron, which is mediated by intra-network inputs from serotonergic and GABAergic neurons.

Title: Neuroanatomical relationship between CO_2 chemosensitive noradrenergic neurons and nitric oxide synthase immunoreactive cells in locus coeruleus

Authors: S. M. JOHNSON[1], *O. DEHKORDI[2], J. ALLARD[1], S. IRAVANI[2], R. M. MILLIS[1], A. JAYAM TROUTH[3]
[1]Dept. of Physiol. & Biophysics, [2]Dept. of Surgery, [3]Dept. of Neurol., Howard Univ., WASHINGTON, DC

Abstract: Locus coeruleus (LC) in the dorsal pons is an important component of the central chemosensitive network participating in the ventilatory response to hypoxia and hypercapnia. Recent studies have demonstrated the involvement of LC noradrenergic neurons in hypoxia and hypercapnia induced hyperventilation. Moreover, nitric oxide (NO) mechanisms appear to regulate the noradrenergic cells of LC and to modulate the hypoxic ventilatory responsiveness of LC neurons. However, the neuroanatomical relationships between LC noradrenergic neurons and NO expressing cells in the LC remain unclear. Therefore, we hypothesized that the neurochemical profile of noraderenergic LC cells might include neuronal NO synthase (nNOS). We evaluated the expression of nNOS with respect to noradrenergic cells of LC by studying Prp57 transgenic mice which express green fluorescent protein (GFP) in their LC noradrenergic cells. We detected nNOS at sites medial to LC, in a small number of cells in LC, as well as in dendritic and axonal processes within LC. However, none of the GFP-positive noradrenergic cells in LC demonstrated NOS-like immunoreactivity. The presence of nNOS immunoreactivity in dendritic and axonal processes in the vicinity of GFP-positive noradrenergic cells confirms the results of previous functional studies concerning involvement of L-arginine and NO signaling mechanisms in the regulation of noradrenergic LC neurons.

Title: Pattern of connexin 26 expression in medulla oblongata

Authors: X. ZHANG[1], G. KOENTGES[1], *N. E. DALE[2]
[1]Sch. of Life Sci., Univ. of Warwick, Coventry, United Kingdom; [2]Univ. Warwick, Coventry, United Kingdom

Abstract: The medulla oblongata contains the chemosensors that impart the sensitivity of breathing to changes in PCO_2. We have previously shown that hemichannels of the gap junction protein connexin 26 (Cx26) are sensitive to changes in PCO_2 around the physiological norm of 40 mmHg. Cx26 is expressed in the chemosensitive areas at the ventral surface of the medulla. To identify more precisely the types of cells involved in the central CO_2 chemosensing, we have studied in detail the expression patterns of Cx26 by immunohistochemistry and in situ hybridization.
Cx26 has three main components of expression in the ventral medulla. Firstly, it is highly expressed in the meninges, specifically in the leptomeningeal cells rather than the endothelial cells of the blood vessels. Secondly, it is expressed in the glial limitans but at a much lower level than in the meninges. In the glial limitans, Cx26 is expressed in the endfeet of glial cells that have cell bodies deep within the medulla. Cx26 is also present in cells on the very ventral surface that have long thin cell bodies in an orientation that parallels the surface. In addition Cx26 is expressed in C-shaped cells that line the entrance of blood vessels into the brain parenchyma. All of these cells in the glial limitans are positive for GFAP. Thirdly, Cx26 is expressed on cells that line blood vessels within the parenchyma. Cx26 puncta are present at the outer surface of the blood vessels between the endothelial cells and the pericytes and glia that ensheath the vessels. Precise knowledge of the cells expressing Cx26 obtained via double in situ staining is required so that we can selectively alter the expression of Cx26 to determine the specific cell types that sense CO_2 in the medulla.

Title: Connexin 26 hemichannels: Receptors for CO2 that contribute to central chemosensitivity

Authors: *L. MEIGH[1], T. L. RODGERS[2], M. J. CANN[3], N. DALE[1]
[1]Univ. of Warwick, Coventry, United Kingdom; [2]Biophysical Sci. Institute, Dept. of Chem., [3]Biophysical Sci. Institute, Sch. of Biol. and Biomed. Sci., Durham Univ., Durham, United Kingdom

Abstract: When CO_2 reacts with H_2O it produces HCO_3^- and H^+. Consequently the partial pressure of CO_2 (PCO_2) closely controls the pH of blood and other bodily fluids. CO_2 homeostasis, through regulation of breathing, is therefore a vital function that helps to control physiological pH. CO_2-dependent ATP release from the chemosensory areas of the ventral medulla plays a key role in triggering adaptive respiratory responses (Gourine et al 2005, Nature 438, 108-111). Our previous work has demonstrated that several β connexin hemichannels respond to changes in CO_2 in the absence of a pH change (Huckstepp et al 2010, J Physiol 588, 3921-3931). Connexin 26 (Cx26) is highly localised to the ventral surface of the medulla oblongata, an important CO_2 chemosensory area and thus binding of CO_2 to Cx26 (and the subsequent opening of Cx26 hemichannels) provides a route for the CO_2-dependent release of ATP (Huckstepp et al 2010, J Physiol 588, 3901-3920). Here we investigate the nature of the interaction of CO_2 with Cx26 to determine whether it is indeed direct and to understand how this interaction leads to opening of the hemichannel.
We have used heterologous expression of various connexins in HeLa cells that have little or no endogenous connexin expression to test the CO_2 sensitivity of connexin hemichannels via CO_2-dependent loading of carboxyfluorescein and whole cell patch-clamping. We found that Cx31, a closely related member of the β connexin family, was insensitive to CO_2. This demonstrates that CO_2 sensitivity is not a property of all β connexins and is instead characteristic of a specific subgroup, comprising connexins 26, 30 and 32. Using sequence comparison of the β connexins, we identified a conserved region which is present in all of the CO_2 sensitive connexins but absent from Cx31. We mutated the Cx31 gene to include this conserved region (mCx31) and found that mCx31 now exhibited sensitivity to CO_2 as determined both by dye loading experiments and patch clamp recordings. We used an elastic network model based simulation designed using the published X-ray structure of Cx26 to investigate the first 25 normal modes for the Cx26 hemichannel and the effect of CO_2-binding on these modes. Binding of CO_2 to the conserved region dramatically altered the contribution of select normal modes to overall hemichannel motion when compared to the unbound state, making the open state more prevalent and greatly

reducing time in the closed state. We suggest CO_2 binding biases the Cx26 hemichannels towards an open state, allowing ATP release until CO_2 is removed.

Title: Contribution of glia-neuron interactions to central control of breathing

Authors: *R. HUDA, D. R. MCCRIMMON, M. MARTINA
Dept of Physiol., Northwestern Univ., Chicago, IL

Abstract: Central chemosensory mechanisms maintain homeostasis of blood and brain pH and partial pressure of carbon dioxide by regulating respiration. Recent studies suggest that glia play an instrumental role in central chemoreception. However, detailed mechanisms of the interaction between glia and neurons within chemosensory brain regions are only partially known. Glial cells express a high density of glutamate transporters, thereby regulating the time course of excitatory synaptic transmission, glutamate spillover across synapses, and ambient concentration of glutamate. Since glutamate transporters are electrogenic, the glial Vm can regulate the activity of these transporters. Here, we test the hypothesis that acidification regulates excitatory neurotransmission within the nucleus of the solitary tract (NTS) by depolarizing glia and, as a result, compromising their ability to uptake glutamate. In accordance, we find that glia in the NTS respond to mild acidification (from pH 7.4 to pH 7.0) with a depolarization (11.2 ± 2.9 mV). This depolarization is accompanied by a decrease in a K+ selective membrane conductance which is occluded by1 mM Ba2+. Moreover, voltage-clamp recordings from glia show that focal application of D-aspartate in the presence of blockers of ionotropic glutamate receptors elicits a voltage sensitive inward current mediated by glutamate transporters. Concurrently, through recordings from NTS neurons, we find that repetitive stimulation (20 pulses at 10 Hz) at/near the solitary tract leads to an AMPA and NMDA receptor mediated slow excitatory potential (SEP; amplitude: 6.55 ± 0.87 mV, Tau decay: 4.3 ± 0.5 sec), likely due to a long-lasting buildup in the extracellular glutamate concentration. Accordingly, the SEP is potentiated by (D,L)-TBOA, a

blocker of glutamate transporters. Interestingly, mild extracellular acidification (from pH 7.4 to 7.0) also potentiates the SEP in a subset of NTS neurons. Together, these experiments suggest that acidification can regulate synaptic transmission within the NTS and provide a potential cellular mechanism involved in central chemoreception.

Title: KCNQ and SK channels contribute to intrinsic excitability of chemosensitive neurons in the retrotrapezoid nucleus.

Authors: X. CHEN[1], J. M. HAWRYLUK[1], A. V. TZINGOUNIS[1], *D. K. MULKEY[2]
[1]Physiol. and Neurobio., [2]Dept. Physiol. and Neurobio., Univ. Connecticut, STORRS MANFLD, CT

Abstract: The retrotrapezoid nucleus (RTN) contains a population neurons (i.e., chemoreceptors) that provide a CO_2/H^+-dependent excitatory drive to respiratory centers to regulate depth and frequency of breathing. Despite the importance of these cells, little is known regarding molecular determinants of their intrinsic excitability or CO_2-responsivness. We have recently determined that RTN chemoreceptors express voltage-gated KCNQ channels and Ca^{2+}-activated small conductance K^+ (SK) channels. Here, we use electrophysiological techniques and pharmacological approaches to explore contributions of these channels to firing rate behavior and CO_2-sensitivity of RTN chemoreceptors in brain slices (300 µM) from neonatal rat pups (P7-12). In the loose-patch current clamp configuration, application of XE991 (10 µM, a selective KCQN channel blocker) increased firing rate by 1.7 ± 0.2 Hz but had no effect on CO_2-sensitivity. In contrast, application of apamin (100 nM, selective SK channel blocker) had no effect on either baseline firing activity or CO_2-sensitivity. Interestingly, the combined application of apamin and XE991 tended to increase burst-like behavior and robustly increased the firing

rate response to CO_2. These results suggest that KCNQ and SK channels are expressed by RTN chemoreceptors, and confer the ability to differentially regulate repetitive firing behavior and CO_2-responsivness. A computational model has been implemented to describe these differentiated effects.

Abstract: Central and peripheral chemoreceptors sense changes in CO_2/H^+ and/or O_2 and communicate this information to cardiorespiratory centers to regulate breathing and sympathetic outflow to ensure adequate ventilation-perfusion matching in tissues. Despite the importance of this reflex, the cellular and neurotransmitter basis for integration of this information in the brainstem is unclear. It has been shown that excitatory drive from peripheral chemoreceptors is relayed through the retrotrapezoid region (RTN) located in the ventrolateral medulla, a region

also known to contribute to central chemoreception. Evidence also suggests that purinergic signaling in this region can influence both respiratory and sympathetic drive, possibly by activation of P2Y1-receptors (P2Y1-R). Therefore, we hypothesize that P2Y1-R represent the molecular basis for central and peripheral chemoreceptor integration at the level of the RTN region. Here, we use *in vivo* and *in vitro* recording techniques to examine the role of P2Y1-R's expressed by RTN region neurons in central and peripheral chemoreception. *In vivo*, unilateral injection of MRS2365, a P2Y1-R specific agonist, into the RTN region of anesthetized adult rats increased mean arterial pressure by 23 ± 1 mmHg (compared to 4 ± 1 mmHg in control experiments) and increased phrenic nerve amplitude and frequency by 59 ± 6% and 53 ± 5%, respectively. Conversely, application of the specific P2Y1-R antagonist MRS2179 decreased peripheral chemoreceptor mediated activation of breathing and blood pressure but did not affect CO2-responsivness. *In vitro*, loose-patch recordings of neurons in slices from rats (P7-12) show that baseline activity and CO_2/H^+-sensitivity of chemoreceptors was unaffected by MRS2179 or MRS2365. Conversely, MRS2179 decreased baseline activity of non-chemosensitive neurons by 42% and MRS2365 increased activity of these cells by 630%. After recording, a subset of CO_2-insensitive P2Y1-expressing cells were filled with biocytin for later immunohistochemical characterization; 4 of 6 cells were immunoreactive for tyrosine hydroxylase and the transcription factor phox2b, suggesting they are C1 cells. These data indicate that i) P2Y1-R are preferentially expressed by C1 cells and contribute to peripheral chemoreceptor modulation of breathing and blood pressure; ii) P2Y1-R are not expressed by ventral surface chemoreceptors and do not contribute to CO2-responsivness in vivo or in vitro; iii) P2-R targeted by CO2-evoked ATP release remain undetermined. These results suggest that purinergic signaling contributes to cardiorespiratory integration at the level of the RTN region.

Title: The role of purinoceptors and astrocytes of the retrotrapezoid nucleus in the chemosensory control of breathing

Authors: C. SOBRINHO[1], A. TAKAKURA[2], V. ANTUNES[1], D. MULKEY[3], *T. S. MOREIRA[1]
[1]Physiol. and Biophysics, [2]Dept. of Pharmacol., Univ. of Sao Paulo, Sao Paulo, Brazil; [3]Dept. of Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT

Abstract: A brainstem region called the retrotrapezoid nucleus (RTN) contains a population of CO2/H+-sensitive neurons that appear to function as important chemoreceptors (i.e., neurons that regulate breathing in response to tissue CO2/H+). Evidence also indicates that CO2-evoked adenosine 5'-triphosphate (ATP) release from RTN astrocytes modulates activity of RTN chemoreceptors in vitro. However, mechanism(s) by which RTN astrocytes sense changes in CO2 in vivo are unknown, and their contribution to central chemoreception remains controversial. The goals of this study are to determine the extent to which ATP contributes to RTN chemoreception in vivo, and whether purinergic drive to RTN chemoreceptors relies on astrocytes. To test the hypothesis that RTN astrocytes contribute to chemoreception by a purinergic mechanism, we used fluorocitrate (FC) to selectively depolarize astrocytes while measuring respiratory output. Mean arterial pressure (MAP) and phrenic nerve activity (PNA) were recorded in urethane-anaesthetized, vagotomized and artificial ventilated male Wistar rats (n=6/group). Unilateral injection of fluorocitrate (1 mM in 50 nl) into the RTN increased PNA amplitude (54 ±5% of baseline) and frequency (38 ±2% of baseline), without changes in MAP (115 ±6, vs saline: 118 ±7 mmHg). Bilateral injections of pyridoxal-phosphate-6-azophenyl-2',4'-disulfonate (PPADS, a P2-receptor antagonist) into the RTN decreased the PNA amplitude (37 ± 3%, vs saline: 54 ± 5%) and PNA frequency (30 ± 1%, vs saline: 38 ± 2%) response elicited by FC. We also use immunocytochemical techniques to show that exposure to hypercapnia resulted in cFos-immunoreactivity in glial fibrillary acidic protein (GFAP)-positive RTN astrocytes. Our results further suggest that RTN astrocytes sense changes in CO2 and release ATP to activate RTN chemoreceptors.

Title: KCNQ channels determine serotonergic modulation of ventral surface chemoreceptors and respiratory drive

Authors: *J. M. HAWRYLUK[1], I. C. WENKER[1], A. C. TAKAKURA[2], T. S. MOREIRA[3], A. V. TZINGOUNIS[1], D. K. MULKEY[1]
[1]Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT; [2]Pharmacol., [3]Physiol. and Biophysics, Univ. of São Paulo, São Paulo, Brazil

Abstract: Chemosensitive neurons in the retrotrapezoid nucleus (RTN) regulate breathing in response to CO2/H+ changes. Their activity is also sensitive to neuromodulatory inputs from multiple respiratory centers, and thus they serve as a key nexus of respiratory control. However, molecular mechanisms that control their activity and susceptibility to neuromodulation are completely unknown. Here, we show in vitro and in vivo that KCNQ channels are critical determinants of RTN neural activity. In brainstem slices (300 µm thick) isolated from rat pups, bath application of XE991 (10 µM, a selective KCNQ channel blocker) increased basal activity by 1.4 ± 0.2 Hz and decreased serotonin responsiveness by ~50%. In contrast, inhibition of SK channels with apamin (100 nM) had no effect on basal activity or serotonin-sensitivity. Unexpectedly, neither XE991 nor apamin had any effect on other raphe transmitters. Further, we show that blocking KCNQ channels in the RTN in vivo blunts the ventilatory response to serotonin in awake and anesthetized animals. Together, these results indicate that i) KCNQ channels regulate tonic activity and serotonin-modulation of RTN neurons in vitro; ii) KCNQ channels are effectors of serotonergic-modulation in RTN neurons in vivo; iii) KCNQ channels contribute to respiratory drive in anesthetized and awake animals. Given that serotonergic dysfunction may contribute to respiratory failure, our findings suggest a new therapeutic avenue for respiratory complications associated with multiple neurological disorders.

Title: Pontine Kölliker-Fuse neurons are important for chemosensory control in conscious rats

Authors: R. S. DAMASCENO[1], *A. T. TAKAKURA[2], T. S. MOREIRA[1]
[1]Dept. of Physiol. and Biophysics, Inst. of Biomed. Sci., Sao Paulo, Brazil; [2]Dept of Pharmacology, Inst. of Biomed. Science, Univ. of Sao Paulo, Sao Paulo, Brazil

Abstract: The pontine nuclei, particularly the Kölliker-Fuse region (KF) and the lateral parabrachial nucleus (LPBN) have been implicated in the maintenance of cardiorespiratory control. However, most of the experiments showing the role of pontine KF region were done in anesthetized animals. Here we evaluated the involvement of KF region and LPBN in the cardiorespiratory responses elicited by chemoreceptor activation in conscious rats.Male Wistar rats (280-300g, n=5-6) with bilateral stainless steel guide-cannulas implanted into the KF region or LPBN were used. In conscious rats, injection of muscimol (120 pmol/100nl) into the KF decreased resting ventilation (979 ± 108, vs. saline: 1402 ± 108 ml/kg/min) and the increase in ventilation produced by hypoxia (8% O2) (1827 ± 61, vs. saline: 3179 ± 335 ml/kg/min) or hypercapnia (7% CO2) (1488 ± 277, vs. saline: 3130 ± 427 ml/kg/min). Bilateral injection of muscimol into the KF did not change resting MAP (4 ± 3, vs. saline: 5 ± 2 mmHg) and resting HR (7 ± 4, vs. saline: 8 ± 3 bpm), however, reduced the hypotension (1 ± 2, vs. saline: -13 ± 4 mmHg) and the tachycardia (58 ± 9, vs. saline: 95 ± 12 bpm) elicited by hypoxia. Bilateral injection of muscimol into the LBPN did not change resting ventilation (1389 ± 55, vs. saline: 1399 ± 32 ml/kg/min), nor the increase in ventilation elicited by hypoxia (2826 ± 61,vs. saline: 3012 ± 44 ml/kg/min) or hypercapnia (3124 ± 78, vs. saline: 3088 ± 88 ml/kg/min). The injection of muscimol into the LPBN increased resting MAP (11 ± 2, vs. saline: 4 ± 2 mmHg), without changing resting HR (3 ± 3, vs. saline: 6 ±4 bpm). In addition, muscimol into the LBPN reduced the hypotension (-5 ± 3, vs. saline: -15 ± 4 mmHg) but did not change the tachycardia (91 ± 12, vs. saline: 87 ± 11 bpm) elicited by hypoxia in conscious rats. The results suggest that

KF region, but not LPBN, have mechanisms to control the ventilation in resting, hypoxic or hypercapnic conditions in conscious rats.

Title: Depletion of methyl-CpG-binding protein 2 (MeCP2) in astrocytes depresses chemosensitivity

Authors: *J. M. BISSONNETTE[1], S. K. GARG[2], D. T. LIOY[2], S. J. KNOPP[1], G. MANDEL[2]

Abstract: The respiratory response to CO_2 is dampened in mouse models of Rett syndrome (RTT) (Am J Physiol 301:C729, 2011; FASEB J 26:894.6, 2012), which may contribute significantly to the frequent apnea observed in the syndrome. Astrocytes on the ventral surface of the medulla respond to changes in CO_2 with an increase in intracellular calcium and secretion of adenosine triphosphate that in turn stimulates adjacent neurons to increase ventilation (Science 329:571, 2010). Additionally astrocytes play a pivotal role in the respiratory disorders of RTT (Nature 475:496, 2011). Here we show that depletion of MeCP2 confined to astrocytes markedly depresses chemosensitivity. Studies were carried out in male mice bearing a tamoxifen-responsive Cre-recombinase under the control of a human glial fibrillary acidic protein (*hGFAP*) promotor and in which loxP sites flanked exon III of *Mecp2* (GFAP-Cre/Flox). CO_2 response was determined by measuring minute ventilation (VE) in 1, 3 and 5% CO_2. Baseline CO_2-response was performed at P40 followed by a 7-day tamoxifen (TAM) regime (100mg/Kg/day) to eliminate the expression of MeCP2 in astrocytes. Respiratory pattern in GFAP-Cre/Flox mice breathing air was not affected by TAM treatment. VE in CO_2, however, was depressed by 61.8±9.5, 60.8±11.7 and 49.9±11.4% at 1, 3 and 5% CO_2 compared to pre-TAM recordings.

Immunohistochemistry of the retrotrapezoid nucleus showed that Phox2b positive, tyrosine hydroxylase negative neurons were not compromised for MeCP2 expression. Although, neurons in the respiratory network ultimately determine the ventilatory response to CO_2, this study demonstrates that loss of MeCP2 in astrocytes alone is sufficient to generate the depressed CO_2 phenotype arguing for a critical role of MeCP2 in glia in regulation of respiratory chemosensitivity.

Title: Pre- and postsynaptic cholinergic modulation of locus coeruleus neurons in wild-type and mecp2-null mice

Authors: *M. F. OGINSKY[1], N. CUI[1], C. M. JOHNSON[1], G. S. CYMBALYUK[2], C. JIANG[1]

Abstract: Rett Syndrome (RTT) is a sex-linked disease which affects 1 in 10,000 live female births and occurs because of mutations to the MECP2 gene. In addition to autistic manifestations, people with RTT have abnormalities in breathing and sleep patterns, which may be attributed to defects in the cholinergic and noradrenergic systems. To understand how cholinergic signaling affects neuronal activity in the locus coeruleus (LC), the major noradrenergic center in the brain, we studied pre- and postsynaptic cholinergic modulation of LC neurons using whole-cell patch clamp in mouse brain slices. Activation of postsynaptic nicotinic receptor caused depolarization, an increase in firing frequency and a decrease in input resistance. Presynaptic cholinergic modulation was examined by analysis of sEPSCs and sIPSCs. Blocking muscarinic acetylcholine receptors increased glutamatergic sEPSC frequency and amplitude. We found that there are two populations of GABAergic input that differentially modulates LC neurons. Nicotinic receptor activation showed an increase in sIPSC frequency and amplitude in one group, whereas the other group showed a decrease in frequency with no change in sIPSC amplitude. sIPSCs were measured from LC neurons of Mecp2-null and wild-type littermates during bath-application of mecamylamine, a nictotinic receptor antagonist. We found that cholinergic modulation was enhanced in Mecp2-null mice compared to wild-type. The decrease in sIPSC frequency was

greater in Mecp2-null mice than in wild-type mice. There was no change in amplitude. These data suggest that the Mecp2 knockout causes a defect in presynaptic modulation of LC neurons involving GABA and cholinergic systems. Lastly, as a first step towards understanding how the dysregulation of these neurons affects breathing and sleep in Mecp2-null mice, we developed a mathematical model of an LC neuron. The model possesses key ionic currents, introduced with Hodgkin-Huxley formalism, and reproduces experimentally observed spiking properties.

Title: GABAergic modulation of locus coeruleus neurons in a mouse model of Rett syndrome

Authors: *X. JIN, W. ZHONG, N. CUI, C. JIANG
Biol., Georgia State Univ., Atlanta, GA

Abstract: Rett Syndrome is an autism spectrum disorder caused by disruption in the Mecp2 gene. This neurodevelopmental disease has multiple neurobiological defects, especially the abnormalities in norepinephrinergic and GABAergic systems. However, the relationship between these two systems is unclear. Therefore, we performed studies to investigate how the Mecp2 knockout affects the GABAergic synaptic neurotransmission in neurons of the locus coeruleus (LC), the prominent norepinephrinergic nucleus in the central nervous system. Experiments were conducted in brain slices obtained from the wild-type and Mecp2-null mice in whole-cell voltage clamp. In comparison to the wild-type, LC neurons from mutant mice showed significant decreases in both frequency and amplitude of spontaneous $GABA_A$-ergic IPSCs. Both the frequency and amplitude of the IPSCs were significantly reduced, while the reduction of the frequency was more obvious than that of the amplitude, suggesting that the LC neurons in mutant mice are deficient in presynaptic GABAergic input. In wt LC neurons, the GABAergic IPSCs were strongly inhibited by the $GABA_B$ agonist baclofen, likely to be mediated by GABAergic auto-receptors. Such a feedback regulation of GABA release from presynaptic terminals seems intact in LC neurons of mutant mice, although it was slightly stronger than that of wild-type mice. These results suggest that the decrease of GABAergic input in LC neurons

may contribute to abnormalities of the norepinephrinergic function seen in the Mecp2-null mice as well as people with Rett Syndrome.

Title: Antagonism of orexin receptors reduces the exaggerated respiratory response to hypercapnia observed in conscious spontaneously hypertensive rats

Authors: *A. LI[1], E. NATTIE[2]
[1]Physiol., Geisel Sch. of Med. at Dartmouth, LEBANON, NH; [2]Physiol., Geisel Sch. of Med. at Dartmouth, Lebanon, NH

Abstract: Orexins (A & B), neuropeptides located in the lateral hypothalamus, are important in the regulation of arousal, food intake, and energy balance, as well as blood pressure and respiration. Studies from our lab have demonstrated that the orexin system is important in central chemoreception and acute, specific antagonism of both orexin receptors by an orally administered dual orexin receptor antagonist, Almorexant (Almxt), significantly reduces the respiratory response to hypercapnia (CO_2 response or central chemoreflex) in wakefulness in the dark period of unanaesthetized, freely moving normotensive rats (*Li & Nattie., J. Physiol 2010*). The spontaneously hypertensive rat (SHR) has in addition to increased blood pressure and sympathetic nerve activity, behavioral hyperactivity and increased prepro-orexin expression in the hypothalamus. We hypothesized that SHR rats may have an exaggerated central CO_2 chemoreflex compared to normotensive Wistar-Kyoto rats (WKY) and this augmented response may be modulated by orexin. Here in conscious SHR rats we found an increased ventilatory (~30%) response to 7% CO_2 in both wakefulness and sleep. Treatment with Almxt reduced the exaggerated CO_2 response to the same level as in WKY rats. Our results link the greater ventilatory response to CO_2 in SHR rats to orexin and suggest a role for orexin in the pathophysiology of the SHR rat.

Title: Refining the serotonergic contribution to central chemosensitivity

Authors: R. D. BRUST[1], *A. E. CORCORAN[2], R. S. RAY[1], E. E. NATTIE[2], G. B. RICHERSON[3], S. M. DYMECKI[1]
[1]Harvard Med. Sch., Boston, MA; [2]Dept. of Physiol. and Neurobio., Geisel Sch. of Med. at Dartmouth, Lebanon, NH; [3]Univ. of Iowa, Iowa City, IA

Abstract: The involvement of brain serotonergic neurons (5HT neurons) in a remarkably wide range of physiological functions and disorders motivates a deeper examination of their heterogeneity with respect to developmental origin, functional properties, and molecular expression. We are using these characteristics to subdivide 5HT neurons and study the involvement of molecularly defined subtypes in different functions. Here, we are interested in the role of 5HT neurons in central respiratory regulation, particularly in the respiratory chemoreflex (defined as an increase in ventilation in response to elevated CO_2 to restore blood gas and pH levels to normal). To test this more definitively, we developed a transgenic mouse strain capable of inducibly and reversibly inhibiting 5HT neuron activity in the awake and behaving mouse, building on the Di system developed by Bryan Roth and colleagues (Armbruster et al 2007). We have found that suppressing neuron activity in all 5HT neurons causes a decreased ventilatory response to breathing 5% CO_2 (Ray et al 2011). We now continued to apply this approach toward silencing subtypes of 5HT neurons in order to identify those that contribute most to the CO_2 respiratory chemoreflex. Using a dual recombinase (Cre and Flpe)-based intersectional genetic approach we have labeled and manipulated (via Di expression) subtypes of 5HT neurons defined by developmental gene expression differences. Present findings highlight a subset defined by having a history of expression of the transcription factor Krox20 (Egr2) and arising from hindbrain rhombomere 5. In vivo plethysmography confirms the importance of these particular neurons in the ventilatory response to hypercapnia. Using patch clamp electrophysiology we find that this same population (identified by eGFP labeling) is chemosensitive in vitro (increase firing rate in response to a decreased bath pH caused by elevating bath CO_2, a property that is not shared among all 5HT neurons). Further, immunohistochemical studies demonstrate projections from eGFP labeled Krox20 5HT neurons

to other brainstem nuclei known to be involved in cardiorespiratory control, including other non-5HT neurons implicated in central chemosensitivity. This work defines a molecular and developmental 5HT neuron subtype involved in CO_2 chemosensitivity and extends our understanding of 5HT neuron biology and its role in a vital homeostatic neuronal network.

Title: Effects of metabolic acidosis on different cell types inside and outside the central nervous system

Authors: A. I. SALAMEH[1], V. RUFFIN[1], *W. F. BORON[2]
[1]Physiol. and Biophysics, [2]Case Western Reserve Univ., CLEVELAND, OH

Abstract: Metabolic acidosis (MAc), a decrease in extracellular pH (pH_o) produced by a decrease in [HCO_3^-] at fixed CO_2, usually induces a large drop in intracellular pH (pH_i) in medullary raphé (MR) neurons. Previous studies have shown that most cell types subjected to MAc exhibit $\Delta pH_i/\Delta pH_o$ that ranges from 20-30% in the non-chemosensitive cells up to 75-80% in the chemosensitive cells. However it is difficult to compare these studies results because they utilized different protocols to induce MAc and different methods to measure pH_i changes. Here we examined the effects of MAc on different cell types outside the central nervous system (CNS) and compared the results with MR neuron responses. We focused our study on two parameters **1)** the cells ability to defend themselves (i.e., have small $\Delta pH_i/\Delta pH_o$ in a first MAc pulse) and **2)** the cells ability to adapt (i.e., have less $\Delta pH_i/\Delta pH_o$ in a second MAc pulse compared with the first MAc pulse). We reduced pH_o from 7.4 to 7.2 by dropping the extracellular [HCO_3^-] from 22 mM to 14 mM at fixed 5% CO_2. Using fluorescence imaging with the pH-sensitive dye 2'-7'-bis(carboxyethyl) 5(6) –carboxy fluorescein (BCECF) to measure pH_i changes, we found that cells have wide range of responses. The skeletal muscle cell line (C2C12) and the freshly isolated guinea pig ventricular myocytes showed a strong defense in the first MAc pulse ($\Delta pH_i/\Delta pH_o$ = 2% for both) and they were able to maintain it in the second MAc pulse (5% and 0%, respectively). Cells from a colon cancer cell line (CT26) had somewhat strong defense in the

first MAc pulse (14%); however, in the second MAc pulse they were not able to adapt (32%). Primary cultures of mouse macrophages had poor defense in the first MAc pulse (46%) and they showed an even greater decrease in their pH_i in the second MAc pulse (52%). The MR neurons had large drop in their pH_i in the first MAc pulse (58%) and they showed small adaptation in the second MAc pulse (52%); however, it was not statistically significant. When we compared the cells from outside the CNS with the MR response to the first and second MAc pulses, we found statistical difference between MR neurons and C2C12, Cardiac, and CT26 cells. There was no statistical difference between MR neurons and macrophages in their responses to the first and second MAc pulses.

Title: Respiratory insufficiency is the likely mechanism of death in West Nile virus (WNV) disease and possibly for other viral encephalitides

Authors: *J. D. MORREY[1], H. WANG[1], V. SIDDHARTHAN[1], R. M. HARPER[2]
[1]Utah State Univ., LOGAN, UT; [2]Dept. of Neurobiology, David Geffen Sch. of Med., Univ. of California at Los Angeles, Los Angeles, CA

Abstract: The mechanism of death is unknown for fatal WNV disease. Since respiratory insufficiency has a poor-prognosis in human WNV disease, we addressed the hypothesis that WNV infects neurological tissues to cause fatal respiratory failure, and that other viral encephalitides may have a similar mechanism of death. WNV infection of rodents suppressed diaphragmatic and intercostal electromyography (EMG) activities, which correlated with medullary infection, in contrast to spinal cord, lung, diaphragm, or other extra-neurologic tissues. Direct ventrolateral medullary injection of viral solution caused rapid and robust loss of diaphragmatic EMG. To determine if this electrophysiological suppression results in respiratory insufficiency, plethysmography patterns in mortally WNV-infected mice were compared to surviving WNV-infected and sham-infected mice. All respiratory parameters measured,

including minute volume, frequency, and peak inspiratory and expiratory volumes, were suppressed in mice that died from infection, but not in surviving WNV-infected or sham-infected mice. Suppression of diaphragmatic EMG was correlated with suppression of plethysmography parameters. SaO_2 values were significantly lower in WNV-infected compared to sham-infected mice. Among respiratory "drives," chemoreceptor processes were specifically impaired; no alert fatally-ill WNV-infected mice improved ventilation to a 7% CO_2 challenge, whereas, 60% of the sham-infected mice responded. Most of the histopathology and WNV-infected cells were located in the ventral medulla. Remarkably, most of the WNV-stained neurons in the rostral ventral medulla co-stained for somatostatin, a neuropeptide with respiratory roles. Histopathology and WNV-infected cells also appeared in the retrotrapezoid nucleus, identified with Phox2b staining. Similar ventilatory suppression also occurred in other viral encephalitic infections, including Japanese encephalitis virus. The likely mechanism of death in WNV, and possibly other viral encephalitides includes viral infection of the ventral medulla leading to fatal respiratory insufficiency.

Title: C1 and RTN neuron stimulation produces cortical arousal in sleeping rats

Authors: *S. B. ABBOTT, M. B. COATES, R. L. STORNETTA, P. G. GUYENET
Dept of Pharmacol., Univ. of Virginia, Charlottesville, VA

Abstract: Sleep disordered breathing is associated with repeated bouts of hypoxia and hypercapnia leading to respiratory, autonomic and cortical arousal. Phox2b-expressing neurons of the retrotrapezoid nucleus (RTN) and C1 adrenergic population in the rostral ventrolateral medulla (RVLM) are important for the cardiorespiratory response to hypoxia and hypercapnia and innervate brain regions that control wakefulness. In this study, we evaluate if selective stimulation of Phox2b-expressing neurons is sufficient to produce sleep to wake transitions during non-rapid eye movement sleep (NREMS) and rapid eye movement sleep (REMS) in rats instrumented for recordings of cortical EEG and neck EMG in a whole-body plethysmography

chamber. Channelrhodopsin2 (ChR2) was restricted to C1 and RTN neurons using a lentivirus vector carrying a Phox2b-dependent promoter. Photostimulation (2-20 Hz, 10 ms pulses) produced frequency dependent transitions from NREMS to wakefulness in 72% of trials ($P<0.001$, N=8). Stimulation during REMS produced transitions to wakefulness in 34% of trials ($P<0.05$, N=7). Photostimulation during NREMS increased tidal volume (TV: +34%) and breathing frequency (fR: +57%), whereas only TV was increased (+24%) during REMS (fR: +5%). The arousal and ventilatory effects of photostimulation were significantly correlated during NREMS and REMS. Photostimulation trials causing cortical desynchronization were associated with single augmented breaths/sighs in 59% of NREM trials and 46% of REM trials. On average, EEG desynchronization preceded sigh breaths by 4.8 ± 1.0 s. This study demonstrates that photostimulation of RVLM Phox2b neurons produces cortical arousal in sleeping rats and facilitates sigh breaths. This work shows that the activation of RVLM Phox2b neurons is sufficient to produce stereotypic cardiorespiratory and cortical arousal responses to hypoxia and hypercapnia during sleep.

Title: Purinergic receptors of the lateral parabrachial nucleus are involved on compensatory responses to hypoxia

Authors: *P. M. DE PAULA, M. F. MENEZES, M. T. FAVERO, J. V. MENANI
Dent. Schl-UNESP, Araraquara, Brazil

Abstract: The lateral parabrachial nucleus (LPBN), a pontine structure located dorsal-laterally to the superior cerebellar peduncle, is part of the hindbrain circuitry involved in the respiratory control. Hypoxia triggers cardiorespiratory responses, including increased pulmonary ventilation (VE) that depends on the peripheral chemoreceptor projections to the nucleus of the solitary tract (NTS) an area strongly connected to the LPBN. Adenosine-5'-triphosphate (ATP) is considered

an important central neurotransmitter and purinergic receptors are present in the LPBN. However, the involvement of purinergic mechanisms of the LPBN in the control of VE during hypoxia is still unknown. In the present study, we investigated the effects of alpha, beta- methyl ATP (a selective P2X purinergic receptor agonist) injected into the LPBN on cardiorespiratory responses to hypoxia in awake rats. Male Holtzman rats (290-310 g, n=5-8/group) with stainless steel cannulas implanted into the LPBN were used. A polyethylene tubing (PE-10 connected to a PE-50) was inserted into abdominal aorta through femoral artery for recording mean arterial pressure (MAP) and heart rate (HR) in awake rats. Respiratory frequency (fR), tidal volume (VT) and VE were recorded by whole-body plethysmography. Rats received bilateral injections of alpha, beta- methyl ATP (2 nmol/200 nl) or saline into the LPBN 5 min before starting the hypoxia. Hypoxia (7% O2 for 60 min) reduced MAP (92 ± 2 mmHg, vs. normoxia: 103 ± 9 mmHg, $p<0.05$), and increased HR (498 ± 9 bpm, vs. normoxia 389 ± 7 bpm; $p<0.01$) and VE (1131 ± 110 ml/min/kg, vs. normoxia 512 ± 33 ml/min/kg, $p<0.01$). Bilateral injections of alpha, beta- methyl ATP into the LPBN enhanced the increase of VT produced by hypoxia (Δ 4.0 ± 0.3 mL/kg, vs. saline 2.8 ± 0.2 mL/kg, or 42% of increase, $p = 0.013$), without significantly changing hypoxia-induced tachypnea (Δ 51 ± 2 cpm, vs. saline 55 ± 9 cpm, or 8% of reduction, $p=0.721$) or VE (Δ 794 ± 68 mL/kg/min, vs. saline 619 ± 110 mL/kg/min, or 22% of increase, $p=0.122$). Bilateral injections of alpha, beta- methyl ATP into the LPBN did not change hypotension (Δ -8 ± 2 mmHg, vs. saline: -11 ± 2 mmHg) and tachycardia (Δ 129 ± 12 bpm, vs. saline 109 ± 9 bpm) during hypoxia. The results showed that the activation of purinergic receptors in the LPBN enhanced the increase of tidal volume produced by hypoxia. However, hypoxia-induced hyperventilation was not significantly increased by the same treatment, probably as a consequence of the reduced, although not significantly, increase in respiratory frequency.

Title: The loss of upper airway muscle activity in sleep is prevented by potassium channel blockade at the hypoglossal motor pool

Authors: *K. P. GRACE[1], R. L. HORNER[2]
[2]Med., [1]Univ. of Toronto, Toronto, ON, Canada

Abstract: Obstructive sleep apnoea (OSA) is a growing public health burden, characterized by repeated episodes of airway narrowing and closure during sleep. Attempts to treat OSA pharmacologically have been unsuccessful because they fail to address the root cause of pharyngeal hypotonia during sleep: the state-dependent inhibition of motoneurons that rhythmically activate the pharyngeal musculature. Increasing potassium conductance is a potential convergent mechanism by which state-dependent neuromodulators reduce motoneuron excitability. Therefore, we determined if potassium channel blockade is an effective strategy to reactivate pharyngeal musculature during sleep. Using reverse microdialysis in 31 rats chronically instrumented for recording of sleep-wake states and respiratory muscle activity, we locally microperfused pharmacological agents at the hypoglossal motor pool to block potassium channels of the three major classes: voltage-gated, inwardly rectifying, and two-pore domain leak channels. Local blockade of voltage-gated and inwardly rectifying potassium channels at the hypoglossal motor pool restored respiratory and tonic pharyngeal motor activity in non-REM and REM sleep to 133-300% of waking values. Importantly, such a complete reversal of airway hypotonia during sleep, particularly in REM sleep, is not possible with other re-activation strategies including blockade of fast-synaptic inhibition or local monoaminergic, glutamatergic, and nicotinic receptor stimulation. Recent efforts to develop OSA pharmacotherapy have focused on two-pore domain type TASK (TWIK-related acid sensitive potassium) channels which are highly expressed at hypoglossal motor neurons. However, we show that activating effects of local TASK channel blockade on pharyngeal motor activity are largely absent in sleep and occur only in wakefulness. Targeting hypoglossal TASK channels may therefore have limited therapeutic potential for the treatment of OSA. Our results show that potassium channel blockade at the hypoglossal motor pool is the most effective strategy identified to date for the preservation of upper airway motor activity during sleep. Potassium channel subtypes, other than TASK, having high hypoglossal expression (i.e. Inwardly rectifying potassium channel 2.4) represent the most significant therapeutic targets for OSA pharmacotherapy.

Title: Severe intermittent hypoxia causes systemic inflammation and impairs respiratory plasticity

Authors: *A. G. HUXTABLE, S. M. SMITH, T. PETERSON, J. J. WATTERS, G. S. MITCHELL
Comparative Biosci., Univ. of Wisconsin - Madison, Madison, WI

Abstract: Inflammation is prevalent in many diseases and disorders that challenge ventilatory control (eg. lung disease, spinal injury, neurodegenerative diseases and obstructive sleep apnea). Although inflammation can enhance and undermine plasticity in various neural systems, little is known concerning the impact of inflammation on plasticity in respiratory motor control. Here, we study the impact of systemic inflammation induced by 8 hrs of severe intermittent hypoxia (sIH, 2 min, 10.5% O2 separated by 2 min normoxia), a model which simulates hypoxic episodes experienced during obstructive sleep apnea. We tested the hypotheses that this model of sIH: 1) upregulates inflammatory genes in the cervical spinal cord; and 2) undermines an important model of spinal respiratory plasticity, phrenic long-term facilitation (pLTF) induced by acute intermittent hypoxia (AIH, 3X5 min hypoxia; 5 min intervals). Preliminary data suggest that sIH significantly reduces pLTF from 33±9% (n=7) in normoxic controls vs. -1±5% (n=6). However sIH had no detectable effect on the short term hypoxic phrenic response. Treatment with the non-steroidal anti-inflammatory drug ketoprofen appears to restore pLTF after sIH (45%, n=1). Spinal gene expression showed elevated IL-1β in isolated microglia (n=8) immediately after sIH, but there were no detectable changes in microglial COX-2 or TNFα. Understanding the impact of systemic inflammation on respiratory plasticity is important since inflammation may undermine the capacity for respiratory compensation during pathological states and the ability to harness respiratory plasticity as a therapeutic strategy in the treatment of devastating breathing disorders, such as cervical spinal injury or motor neuron disease.

Title: Nutrient availability defines the expression and localization of SIRT1 in PC12 cells

Authors: K. FUJINO, Y. HASHIMOTO, *T. NEDACHI
Toyo Univ., Gunma, Japan

Abstract: Nutrient availability is one of the most important signals that regulate cellular fates including cell growth, differentiation, and death. Accumulated evidence suggested NAD^+-dependent histone deacethylase, sirtuin 1 (SIRT1) plays prominent role on connecting between changes in nutritional availability and regulation of cellular functions. SIRT1 was initially identified as a senescence-regulating enzyme; however, recent studies suggested that SIRT1 not only regulates senescence of cells but also the other cellular functions, including skeletal muscle differentiation and metabolic regulation in hepatocytes. SIRT1 expression is also observed in the nerve cells; however, the role of SIRT1 and/or expressional regulation of SIRT1 are not fully understood. The aim of present study is that to elucidate whether and how the glucose availability affects the expression and localization of SIRT1 using PC12 cells.
Initially, we found the total expression level of SIRT1 in PC12 cells was reduced in response to increasing in glucose availability. The gene expression of SIRT1 was also produced similar changes. Next, we checked whether the intracellular localization of SIRT1 was changed by glucose availability. Upon increasing in glucose availability, SIRT1 localization was gradually changed from nucleus to cytoplasm. During this high glucose-dependent locational change, SIRT1 appeared to be glycosylated. Currently, the impact of this glycosylation on SIRT1 function was unclear; however, it could be suggested that the modification of SIRT1 protein and the regulation of SIRT1 amounts cooperatively control acethylation of intracellular proteins, thereby cellular functions. We finally confirmed physiological relevance of this SIRT1 regulation by high glucose condition because SIRT1 overexpression is known to stimulate neurite outgrowth. As expected, high glucose condition attenuated neurite outgrowth induced by NGF.In conclusion, in this study, we successfully identified several mechanisms of glucose-dependent SIRT1 regulation. Because SIRT1 is now considered as neuroprotective proteins, further studies on this issue may provide methodological advance against neurodegenerative diseases.

Title: Fluoxetine alters the neurogenomic profiles and anxiety-related behavior in wild-derived zebrafish

Authors: *R. Y. WONG[1], S. OXENDINE[2], X. YAO[2], J. GODWIN[2]
[1]Biol., North Carolina State Univ., Raleigh, ; [2]Biol., North Carolina State Univ., Raleigh, NC

Abstract: Anxiety disorders account for a large proportion of mental illnesses with over 40 million people in the U.S. being diagnosed with an anxiety-disorder. Studies have shown that in humans and animals, treatment with selective serotonin reuptake inhibitors (SSRIs; e.g. fluoxetine) can reduce anxiety and anxiety-like behaviors. Yet treatments with SSRIs in humans can vary in their efficacy and have many side effects due to the wide ranging influences of serotonin. To better understand the molecular consequences of fluoxetine treatment, we chronically administered fluoxetine to zebrafish (*Danio rerio*), which is an emerging model system for the study of anxiety-related behaviors, and characterize the brain transcriptome using RNA-Sequencing. Both racemic and stereoismeric fluoxetine treatment had anxiolytic effects on anxiety-related behaviors in our wild-derived strains using the Novel Tank Diving Test paradigm. We identified 637 genes that were differentially expressed between racemic fluoxetine treatment and control. Gene ontology (GO) analyses reveal that over half of the genes that are over-enriched belong to Biological Processes with metabolic functions. We observed similar GO categorization patterns when separately examining genes significantly up-regulated in fluoxetine (352) and control (285) treatments. Further we observed some consistent patterns of expression in putative rodent neurochemical biomarkers of fluoxetine efficacy and stress response. Overall, we describe the influences of fluoxetine on the transcriptome and point to other potential targets and effects of the drug.

Title: Sp1 serves pivotal role in negative regulation of PAC1 gene expression by involvement of transglutaminase 2.

Authors: A. MIURA, Y. KAMBE, K. INOUE, T. KURIHARA, *A. MIYATA
Pharmacol., Kagoshima Univ. Grad Sch. Med. & Dent. Sci., Kagoshima, Japan

Abstract: Pituitary adenylate cyclase activating polypeptide (PACAP) functions as a pleiotrophic neuropeptide through three types of G protein-coupled receptors (GPCRs), PAC1, VPAC1, and VAPC2. PAC1 binds exclusively to PACAP with higher affinity than VIP. Recently, we reported that nerve growth factor augmented PAC1 gene expression through the activation of Sp1 via Ras/MAPK pathway in PC12 cells (Miura A, et al., 2012). On the other hand, it was reported that global ischemia induced a persistent reduction in the hippocampal PAC1 expression, which is moderately localized in the CA1 pyramidal cell layer and highly in the granule cell layer (Riek-Burchardt M, et al., 2010). Further, we also observed that PAC1 expression in Neuro2a cells was transiently suppressed during in vitro ischemic condition, oxygen-glucose deprivation (unpublished data). Since endoplasmic reticulum (ER) stress is induced by ischemia, we attempted to clarify whether Tunicamycin (TM), which induces ER stress, affects on the expression of PAC1. As a result, TM potently suppressed the expression of PAC1 in addition to induction of apoptosis. Salubrinal, a selective inhibitor of the ER stress-induced pancreatic ER kinase (PERK) signaling pathway, cancelled its suppression. Then we attempted to elucidate the molecular mechanism of negative regulation of PAC1 expression due to ER stress. Luciferase reporter assay demonstrated that the mutated vectors for each 5 Sp1 site at -314/-305, -282/-273, -116/-107, +184/+188 or +227/+236bp cancelled the suppression due to ER stress. Further western blot analysis showed that protein level of Sp1 was significantly decreased, although its mRNA level did not changed. Recently it was reported that transglutaminase 2 (TG2), which is a cross-linking enzyme and implicated in apoptosis, is induced in the nuclei by ER stress, resulting in crosslinking and inactivation of Sp1 (Tatsukawa et al., 2009). Then we pretreated the cells with cystamine, which is a TG activity inhibitor, before TM treatment. As a result, suppression of PAC1 gene expression was significantly cancelled as well as Salubrinal. These suggest that Sp1 might be a crucial transcriptional element in negative regulation of PAC1 gene expression with involvement of TG2 in ER stress.

Title: Localization of the corticosterone-sensitive organic cation transporter 3 (OCT3/Slc22a3) mRNA and protein in the male rat brain via *in situ* hybridization and immunohistochemistry

Authors: *J. S. TALBOOM[1,2], J. MOLINARO[1], H. C. TOMPKINS[1], L. MUMAW[1], C. A. LOWRY[3], K. J. RENNER[4], M. ORCHINIK[1]
[1]Sch. of Life Sci., Arizona State Univ., Tempe, AZ; [2]Arizona Alzheimer's Consortium, Phoenix, AZ; [3]Dept. of Integrative Physiol. and Ctr. for Neurosci., Univ. of Colorado, Boulder, CO; [4]Dept. of Biol., Univ. of South Dakota, Vermillion, SD

Abstract: The organic cation transporter 3 (OCT3/Slc22a3) is a low affinity and high capacity polyspecific monoamine transporter found in the human and rat brain. OCT3 is believed to clear extraneuronal monoamines (e.g., serotonin, norepinephrine, and dopamine), thereby helping to terminate their signal after release. OCT3 may complement other specific (e.g., SERT, DAT, and NET) or polyspecific (e.g., PMAT, OCT1, and OCT2) transporters in regions of the brain that are innervated by monoaminergic terminals. However, OCT3 is unique in that it is the only known monoamine transporter inhibited by physiological levels of corticosterone (CORT). Among other stress-related neural processes, CORT-mediated inhibition of OCT3 may modulate the hypothalamic-pituitary-adrenocortical (HPA) axis via alterations in monoaminergic neurotransmission. We hypothesize that OCT3 functions in hierarchical systems regulating the HPA axis, including areas of the hippocampus, the amygdala, and the hypothalamus, to increase extracellular monoamine concentrations during the acute stress response. Previous studies determining the location of OCT3 mRNA in the rat brain have been contradictory. Therefore, we determined the location of OCT3 mRNA and protein through *in situ* hybridization (ISH) and immunohistochemistry (IHC). In order to examine OCT3 mRNA in the brains of young male Sprague-Dawley rats, digoxigenin (DIG)-labeled OCT3 riboprobes were *in vitro* transcribed in a process starting with RNA isolated from the rat brain. These riboprobes were then used to perform ISH in rat brain sections following a standard DIG ISH protocol. Separate brain sections were processed for OCT3 IHC following a standard chromogenic protocol. Our results indicated that OCT3 mRNA is found in the hippocampus, amygdala, and hypothalamus. Furthermore, the OCT3 mRNA distribution corresponded to the OCT3 protein distribution in these brain regions.

Collectively, these data support the conclusion that CORT-sensitive OCT3 is expressed in brain regions that mediate behavioral and neuroendocrine stress responses, which may lead to a better understanding of CORT-mediated regulation of the HPA axis.

Title: Integrative adaptive responses to mild mitochondrial uncoupling emphasize arc/arg3.1 signaling and tsc2-associated mtor inhibition

Authors: *D. LIU
Lab. of Neurosciences, NATIONAL INSTITUTE ON AGING/ NATIONAL INSTITUTES OF HEALTH, BALTIMORE, MD

Abstract: At the organismal level, mild energetic stress (e.g., dietary restriction and exercise) enhances neuroplasticity and increases the resistance of the nervous system to injury and disease (Stranahan and Mattson, *Nat. Rev. Neurosci.* 2012; 13: 209-216). At the cellular level, mild mitochondrial uncoupling enhances energy expenditure by dissipating energy production in mitochondria. In the present study we examined the effects of mild energetic stress on molecular signaling networks related to bioenergetics in cultured rat cerebral cortical neurons and in the brains of adult mice. Exposure of cultured cortical neurons to subtoxic levels of the mitochondrial uncoupling agent 2, 4-DNP elicited a stress response as indicated by enhanced glucose uptake and NADH oxidation. C57BL6 mice were exposed to 2, 4-DNP at a dose that was previously shown to be neuroprotective, and gene microarray analysis was performed on RNA samples isolated from cortical tissue after 2, 4-DNP administration. Analysis of bioenergetics-related signaling pathways and network linkage analysis revealed prominent up-regulation of TSC2 (tuberous sclerosis complex), which is linked to inhibition of mammalian target of rapamycin (mTOR) complex mTORC1 and mTORC2/Rheb signaling. Genes related to insulin receptor signaling pathway and PI3K/pAkt signaling were mostly down-regulated. Genes encoding BDNF and Arc/Arg3.1, two important stress- and activity- responsive proteins that influence neuronal network activity and energy metabolism were also up-regulated. Changes in the levels of several of the key proteins encoded by the up- and down-regulated genes were

confirmed by immunoblot analysis. The increased Arc/Arg3.1 expression was associated with changes in genes involved in the regulation of cellular endocytosis. Our findings suggest that mild mitochondrial uncoupling induces a coordinated cellular network of bioenergetics- and plasticity-related stress responses in cerebral cortical neurons.

Title: Differences in pattern of extracellular regulated-protein kinase activation in male and female C57BL/6 mice caused by stress

Authors: *M. GARG[1], A. TSENG[1], M. MILET[1], M. AZIZY[1], A. HAMID[2], P. MARQUEZ[1,2], K. LUTFY[1,2]
[1]Pharmaceut. Sci., Western Univ. Of Hlth. Sci., Pomona, CA; [2]Charles Drew Univ. of Med. and Sci., Los Angeles, CA

Abstract: Activation of extracellular regulated-protein kinase (ERK) has been implicated in neuronal plasticity, mood disorders and drug addiction. In the present study, we assessed whether there is a gender-related difference in ERK activation, as measured by the level of phosphorylated ERK (p-ERK) following swim exposure. Male and female C57BL/6 mice were allowed to freely swim in 23°C-water for 15 min. The amount of time the animals remained immobile was recorded and used as a measure of depressive-like behaviors. At the end of swim, mice were sacrificed and their brains were removed. Different brain regions were dissected out, homogenized in RIPA buffer and assayed for protein concentration. A sample containing 25 µg of protein was blotted and assayed for phosphorylated ERK using the primary (phospho-Erk1/2Thr202/Tyr204(D13.14.4E, Rb mAb), Cell Signaling Technology; 1:1000 dilution)and secondary (anti-rabbit HRP-linked antibody (7074), Cell Signaling Technology; 1:1000 dilution) antibodies. Samples were also assayed for beta-actin using the primary (anti-actin mouse monoclonal IgG (MAB1501), Millipore; 1:2000) and secondary HRP-conjugated goat anti-mouse IgG (12-349), Millipore; 1:2000) antibodies. The level of p-ERK activation was

expressed as percent of p-ERK level in naïve animals for each gender. Immobility time appeared to be higher in female than male mice but the difference was not statistically significant ($p>0.05$). Highest levels of p-ERK were found in the cerebellum followed by the cortex, striatum, hippocampus, midbrain, hypothalamus and pons. Although p-ERK level was increased in almost all brain areas in male mice following the 15-min swim exposure, it was not altered in female mice except in the cortex (increased by about 50%) and hippocampus (reduced by about 20-30%). However, the differences in ERK activation and immobility time observed between male and female mice were not statistically significant ($p>0.05$). These results suggest that there exist no gender-related differences in immobility time or ERK activation following acute stress exposure.

Title: Fate of internalized corticotropin releasing factor receptors in the rat locus coeruleus in a social defeat paradigm

Authors: *B. A. REYES[1], K. VAKHARIA[1], S. K. WOOD[2], R. J. VALENTINO[2], E. J. VAN BOCKSTAELE[1]
[1]Dept Neuroscience, Farber Inst. Neurosci, Thomas Jefferson Univ., PHILADELPHIA, PA; [2]Anesthesiol. and Critical Care Med., Children's Hosp. of Philadelphia, Philadelphia, Philadelphia, PA

Abstract: Exposure to repeated stress is known to contribute to the onset of a number of psychiatric disorders. In rodents, social stress can be modeled using the social defeat paradigm. Previously, it was shown that rats exposed to social defeat cluster into two distinct subpopulations defined by the latency to assume the defeat posture; namely, short latency (SL) and long latency (LL). These subpopulations exhibit distinct endocrine and behavioral phenotypes as well as different expression levels of corticotropin-releasing factor (CRF) and

CRF receptor (CRFr) in selected brain regions. The locus coeruleus (LC) norepinephrine system is a stress-sensitive region whose neurons exhibit changes in the cytoplasmic vs plasmalemmal distribution of the CRF receptor following social defeat. In the present study, high-resolution electron microscopy using different sized immunogold-silver particles to detect CRFr and a marker of early endosomes was used to probe the fate of internalized receptors within LC neurons. Sprague-Dawley rats were subjected to repeated (5 days) social defeat or control manipulation and perfused 24 h after the last session. Sections through the LC were analyzed for the association of CRFr with early endosome antigen 1 (EEA), a marker of early endosomes (Arjonen et al., Traffic, 13: 610-625). Following social defeat, LL rats (n = 3) exhibited an increased association of CRFr with EEA as evidenced by an increased in proximity (0.155 μm) of differentially sized gold-silver particles indicative of CRFr and EEA within the cytoplasmic compartment compared to control (n = 4) and SL (n = 3) rats. These results indicate that following social defeat, CRFr is internalized and potentially recycled back to the cell surface. Additional time points are required to determine whether CRFrs return to the cell surface in LL rats. Adaptations in the distribution of CRFr in LC neurons may have important consequences on behavioral and physiological responses to stress.

Abstract: Diary exposition to electromagnetic fields generated by various electric devices as electrical installation, can origin a chronic exposition to extreme low frequency electromagnetic

fields (ELF-EMF). The interaction between this type of radiation and the biological systems still unclear, but there are some theories that try to explain this interaction. One of them is the half life extension of free radicals that can produce damage of tissues. The brain is particularly vulnerable to damage by free radicals due to its high metabolic rate and its low antioxidant enzymes levels. Lipids play an important role in nervous system. It is known that physical/physiological stress has an effect in the oxidative status balance, leading to oxidative stress and deterioration of lipid membranes. The aim of the present study was to evaluate the effects of chronic exposure (2 h/day, for 21 days) to ELF-EMF (60 Hz, 2.4 mT), movement restraint (MR, 2h/day, for 21 days) and both, in the brain lipid profile of adult Wistar rats. After the treatments, the rats were killed by cervical dislocation. The brains were dissected and separated into three fractions: cerebral cortex, cerebellum and subcortical structures. This procedure was made to see treatment differences in brain regions. The brain fractions were homogenized and total lipids were extracted with Folch's method. Total cholesterol, triacylglycerols, non-esterified fatty acids and phospholipids were determined in the samples. A fraction of total lipid extract was used to determine the non-saturated/saturated lipids, through gas chromatography. Preliminary results showed that, there are not statistical differences in content of triacylglycerols in any of the fractions analyzed. The cholesterol content showed a significant increase ($p<0.05$) in the cortex and cerebellum of groups exposed to EMF. The phospholipid content showed a significant increase in the groups exposed to EMF ($p<0.05$) in cerebral cortex and the group exposed to EMF and MR ($p<0.05$) in the subcortical structures. The gas chromatography showed an increase in the unsaturated fatty acids and decrease in saturated fatty acids in the cortex ($p<0.05$). These preliminary data suggest that the EMF effects are specific in brain lipid composition and for some brain regions and, deserve more investigation.

Abstract: The dopamine neurotransmitter activates D1-like (D1, D5) and D2-like dopamine receptors (D2, D3, and D4). The D2-like receptors modulate adenylate cyclases, ion channels and protein kinase cascades. Previous studies have reported antidepressant-like activities of the dopamine D2/D3 receptor agonists such as pramipexole and PD128907. The D3 receptor in particular has been implicated in the pathophysiology of major depression. We have previously characterized two properties that distinguish D3 from D2 receptors. The tolerance property of the D3 receptor is the progressive decrease in receptor signaling function upon repeated stimulation by classical agonists, including dopamine. The slow response termination (SRT) property is the prolongation of time taken to terminate the signaling function of the D3 receptor, after removal of the agonist. Interestingly, while PD128907 induces severe D3 receptor tolerance and SRT, we have recently identified a novel D3 receptor agonist, ES609, that does not induce tolerance and SRT. The objective of this study was to compare the effects of ES609 and PD128907 on depression induced by prolonged restraint stress. The antidepressant efficacy of ES609 and PD128907 were compared using the Forced Swim test (FST). A novel Drd3-EGFP transgenic mouse model was utilized for these studies. FST measures induction of a depressed state by forcing mice to swim in a narrow container from which they cannot escape. A characteristic immobile posture is adopted after a brief period of vigorous activity. Depressive state is measured by duration of immobility and frequency of immobility bouts. To reduce individual variability, Drd3-EGFP mice were submitted to 6 min of pre-training in the FST on day 1. On day 2, the mice were subjected to a “mild stressor” for 2 hrs in which the animal was restrained in a 50 ml plastic tube. Subsequently, we subcutaneously administered 10 mg/kg ES609, 0.05mg/kg PD129807, or saline vehicle 30 min before the test. Each animal was then submitted to 6 min of FST and the total duration of immobility and the frequency of immobility bouts measured during the last 4 min of the test. No baseline differences were observed between the various experimental groups during the pre-training FST. ES609 produced a significant reduction in immobility as well as frequency of immobility bouts in the stressed animals compared to PD128907 and saline vehicle. This study showed that ES609 is more effective than a D3 selective dose of PD128907. The results suggest that the novel atypical D3 receptor agonists that do not induce D3 receptor tolerance and SRT might have antidepressant-like activity in a restraint stress model.

Title: Ovarian steroids regulate the gene expression of GR co-chaperones Fkbp5 and Ppid

Authors: *C. H. BOURKE[1], S. A. MALVIYA[2], S. D. KELLY[3], C. S. HARRELL[3], G. N. NEIGH[3]
[1]Psychiatry & Behavioral Sci., [2]Psychiatry & Behavioral Sci.; Physiol., Emory Univ., ATLANTA, GA; [3]Psychiatry & Behavioral Sci.; Physiol., Emory Univ., Atlanta, GA

Abstract:
A common clinical finding in patients with major depression is hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis, the system that regulates the stress response. It has been suggested that alterations in the glucocorticoid receptor (GR)-mediated negative feedback prolongs the activation of the HPA axis, leading to the dysfunction observed in a significant subset of depressed patients. Previous studies from our lab show a sexually dimorphic change in the expression of molecular regulators and a reduction in GR sensitivity in female Wistar rats that were exposed to chronic adolescent stress. In addition, chronically stressed female rats displayed a more pronounced release of ovarian and stress hormones in response to an acute stressor. These changes could underlie the female vulnerability to developing depressive-life behavior (Bourke et al 2012). The present study tests the hypothesis that ovarian steroids are sufficient to induce alterations in the GR co-chaperone system . Using Real-Time PCR, we determined the extent to which serum ovarian steroids and uterine weights predicted the expression of GR and two co-regulators of GR sensitivity, *Fkbp5* and *Ppid*.Then, we assessed the impact of corticosterone (cort), estradiol (E2) and progesterone (P4) exposures on the expression of these genes *in vitro* in HT-22 mouse hippocampal neurons. Uterine weights positively correlated with the expression of *Fkbp5* and *Ppid*, but did not predict the expression of *Gr*. In HT-22 neurons, cort increased the expression of *Fkbp5* in a dose dependent manner. At the highest dose of cort tested, the expression of *Fkbp5* was 1.5 fold higher than baseline. E2 treatments administered
in conjunction with cort augmented the increase in *Fkbp5* expression. Exposure to E2 decreased the expression of *Ppid* in a dose-dependent manner, irrespective of cort exposure. P4 did not alter expression of PPID or Fkbp5 with or without cort co-exposure. Collectively, these results suggest that the expression of GR co-regulators is directly influenced by exposure to E2, providing a basis for the attenuated GR translocation observed in females with a history of chronic stress

Title: Stress induced phosphorylation of snap-25

Authors: *S. YAMAMORI[1], D. SUGAYA[1], Y. IIDA[2], H. KOKUBO[1], M. ITAKURA[1], E. SUZUKI[3], M. KATAOKA[4], H. MIYAOKA[2], M. TAKAHASHI[1]

Abstract: SNAP-25, a t-SNARE protein, plays a crucial role in neurotransmitter release by exocytosis. Protein kinase C phosphorylates SNAP-25 at Ser^{187} and enhances hormonal release from adrenal chromaffin cells and insulin-secreting cells, however the physiological significance of SNAP-25 phosphorylation in brain function still remains unclear. In the present study, we found that the phosphorylation level of SNAP-25 increased rapidly in mouse brain following restraint stress in cold water. The basal and stress-induced phosphorylation of SNAP-25 was high in stress-related brain regions, including cerebral cortex, hippocampus and amygdala, and the extent of phosphorylation increased with increasing amounts of stress. Among seventeen

phosphoproteins tested, only three proteins including SNAP-25 were phosphorylated by cold restraint stress. Intravenous application of adrenaline elevated the phosphorylation level of SNAP-25, however stress-induced phosphorylation was still observed in adrenalectomized mice, indicating that phosphorylation of SNAP-25 is regulated through both central and peripheral mechanisms. Serum corticosterone levels of a SNAP-25 mutant mouse with a single amino acid substitution at S187A (*Snap-25*$^{S187A/S187A}$ mutant mice) displayed normal elevation after cold-restraint stress. In stressful conditions, both wild type and SNAP-25 knock-in mice exhibited a strong reduction in feeding. Although food intake gradually recovered to normal levels in wild type mice, it never recovered in *Snap-25*$^{S187A/S187A}$ mutant mice. These results indicate that phosphorylation of SNAP-25 plays important roles in stress response, possibly in the adaptation to stress.

Title: Expression of mineralocorticoid receptor mRNA in response to mate pair separation in male and female zebra finches.

Authors: A. J. KESNER, *F. N. MADISON, G. F. BALL
Psychological and Brain Sci., Johns Hopkins Univ., Baltimore, MD

Abstract: Amongst vertebrates, several different mating patterns exist. Social monogomy, for example, is most prevalent in avian species. The highly social zebra finch forms and sustains lifelong monogamous pair bonds in the wild. Zebra finches also readily form pair bonds in the laboratory making them a good model to investigate the physiological consequences of mate pair separation. There is evidence that mate separation is stressful. Several studies have shown that separating zebra finch pairs elicits changes in behavior (e.g. increased song rates) and increases in the concentration of corticostere (CORT). However, the underlying neural mechanisms modulated in response to mate pair separation remain to be elucidated. In this study, we investigated possible changes in mineralocorticoid receptor (MR one of the receptors CORT

binds to) mRNA expression in response to acute mate pair separation in male and female zebra finches. Male and female zebra finches were maintained on long days (14L:10D) and established mate pairs were confirmed when behavioral criteria such as allopreening, clumping, and nest box cohabitation was observed. 16 mate pairs and 16 stimulus females (N=48) were assigned to one of six treatment groups: male and female birds were either separated from their mate, separated from the stimulus female, or handled but not separated from mate pair (control). After 48 hours in the new housing condition, brains were collected, frozen, and later micropunches from the hippocampus were analyzed via qPCR for MR mRNA. Blood was collected prior to (baseline) and at the end of the study. Plasma samples were analyzed for CORT via enzyme-immunoassay.No significant differences in MR mRNA expression in the hippocampus as a function of mating state were detected in male or female zebra finches. No differences in plasma CORT concentrations were observed in either baseline or in response to mate pair and stimulus female separation. Our study suggests that the psychosocial stress of mate pair separation was not sufficient in altering hippocampal MR mRNA, a neuroendocrine marker of the stress response, in male and female zebra finches.

Title: Circadian alterations in cytokine expression and adrenal hormone production

Authors: *C. M. HUESTON, T. DEAK
Behavioral Neurosci. Program, Dept. of Psychology, Binghamton Univ., BINGHAMTON, NY

Abstract: Acute stress exposure is associated with changes in a variety of hormonal, neural, and immune-related factors. Recent studies from our lab and others indicate that stress related changes in central interleukin-1β (IL-1) expression, in particular, vary remarkably depending on the time of day during which stress is imposed. Given that multiple hormones released in response to stress, including both progesterone and corticosterone (CORT), have been shown to constrain inflammatory processes under varying conditions, the goal of the following series of experiments was to clarify circadian fluctuations in these hormones and how they might impact the response to stress challenges imposed at the light-dark transitions. Adult male Sprague-

Dawley rats (N=16) were killed at either ZT0 (offset of active cycle) or ZT12 (onset of active cycle) and fluctuations in the levels of plasma hormones, adrenal enzymes responsible for the conversion of progesterone to CORT, and paraventricular nucleus (PVN) and adrenal gland cytokine mRNA levels were measured. Results indicate that while as expected, CORT increased at ZT12, in male rats progesterone did not appear to fluctuate across the circadian cycle. Within the PVN no changes in IL-1 or cfos mRNA expression was found between the two time points, however IL-6 expression was increased at ZT12. Within the adrenal gland, gene expression levels of housekeeper genes (β-Actin, GAPDH, cyclophilin) also showed differences as a function of circadian timing. As a result, target genes (IL-1, cfos, IL-6, TNFα, COX2, CYP21A1, CYP11B1) were analyzed independent of housekeeper expression. Commensurate with other published findings, we found that IL-1 mRNA levels were lowest at at ZT12. In addition, both CYP21a1 and CYP11b1 mRNA expression levels were suppressed at ZT12, which is surprising given the role of these enzymes in converting progesterone to CORT. However, as mRNA levels may not represent actual protein expression or enzyme activity, other measures of enzyme function are currently under examination. In addition, as the adrenal gland appears to have strong circadian rhythmicity, we aim to examine the mechanistic link between circadian clock genes and the expression of inflammatory factors within the adrenal glands.

Title: Extensive pre-mRNA splicing of REST/NRSF and its relevance to retinoic acid-induced differentiation of SH-SY5Y cells

Authors: *G.-L. CHEN, G. M. MILLER
Neurosci., Harvard Med. Sch/NEPRC, SOUTHBOROUGH, MA

Abstract: Emerging evidence suggests that alternative pre-mRNA splicing, a major mechanism for both transcriptome and proteome diversity, extensively exists in the brain and plays a role in adaptive responses to environmental stimuli. The repressor element silencing transcription factor (REST), also known as the neuron-restrictive silencing factor (NRSF), acts as a hub for the recruitment of diverse chromatin modifiers to target gene loci important in behavior, neurogenesis and tumorigenesis. We performed a systematic and comprehensive analysis of REST pre-mRNA splicing and examined its relevance to the differentiation of human neuroblastoma SH-SY5Y cells by retinoic acid (RA). Specifically, cDNA samples from various neuronal and non-neuronal tissues and cell lines were amplified by numerous REST-specific primer sets for the detection of potential splice variants, and 5'- and 3'-ends of mRNAs were identified by RACE. With this approach we identified a total of 34, mostly cell-/tissue-specific, splice variants of REST that result from all types of splicing (e.g. exon skipping, alternative 5'- and 3'-splice site, intron retention and mutually exclusive exon), along with a number of novel alternative exons, promoters and poly(A) sites. While some splice variants without a stop codon may function as non-coding RNA, numerous splice variants with a premature stop codon are predicted to encode truncated proteins that functionally parallel REST4, a neuron-specific, truncated REST isoform lacking the C-terminal repression domain critical for transcriptional repression. Using quantitative real-time PCR, we assessed the expression of specific REST splice variants as well as some neuron-specific target genes (BDNF, SCG10 and Synaptin I) in non- and RA-differentiated SH-SY5Y cells. We found a global increase in the expression of REST splice variants and target genes in the RA-differentiated SH-SY5Y cells, implying that alteration in REST expression may underlie the activation of neuronal genes during neurogenesis. Our findings suggest that REST undergoes extensive pre-mRNA splicing, resulting in numerous REST mRNA isoforms that likely have distinct biological functions. The regulation and biological function of the newly-identified REST variants is currently under investigation.

Title: Microrna-mediated regulation of midbrain urocortin-1

Authors: *A. ASCHRAFI[1], J. M. VERHEIJEN[2], N. F. OLDE LOOHUIS[1], P. M. GORDEBEKE[2], T. KOZICZ[2]
[1]Dept. of Cognitive Neurosci. (route 126), Donders Inst. For Brain, Cognition, and Behaviour, Nijmegen, Netherlands; [2]Dept. of Cell. Animal Physiology, Donders Inst. For Brain, Cognition, and Behaviour, Radboud Univ., Nijmegen, Netherlands

Abstract: Evidence suggests that the centrally projecting neurons in the midbrain Edinger-Westphal nucleus (EWcp) play an important role in controlling/modulating the animal's stress-response. Previous research has demonstrated stress-associated regulation of urocortin-1 (Ucn1), a centrally acting stress neuropeptide in the EWcp. However, the mechanisms controlling the expression of Ucn1 remain largely elusive. Increasing evidence points to a critical role of microRNA (miRNA) in several brain processes, including neuronal stress response. MiRNAs are a class of small non-coding RNA molecules that regulate the expression of several target genes at the post-transcriptional level. We investigated whether miRNAs can potentially modulate the expression of Ucn1, and examined possible upstream miRNAs that have the capacity to bind the 3' untranslated (3'UTR) region of Ucn1 mRNA. Sequence analysis of the 3'UTR of rat Ucn1 mRNA revealed the presence of putative binding sites for a number of brain-specific miRNAs including miR-326. Thus, miR-326 may have the capacity to modulate Ucn1 levels in neurons. Transfection of miR-326 mimics into rat primary midbrain neurons resulted in a significant decrease of Ucn1 mRNA and protein levels. Conversely, the transfection of synthetic anti-miR-326 oligonucleotides increased Ucn1 mRNA and protein levels in cultured midbrain neurons. Taken together, these results point to a molecular mechanism in which miR-326 acts as a potential upstream regulator of Ucn1 by binding to the 3'UTR of the Ucn1 mRNA, and consequently may play an important role in modulating the neural stress response.

Animal & Human Physiol., Gdansk Univ., Gdansk, Poland

Abstract: The role of DNA cytosine methylation, an epigenetic regulator of chromatin structure in brain remains unclear and DNA methylation is believed to be stable postnatally in adult mammals. However, recent data suggest changes in DNA methylation in the postnatal brain. Therefore, we examined by NimbleGen Mouse DNA Methylation 3x720K CpG Island Plus RefSeq Promoter Arrays the DNA methylation status at 20 404 promoters of 22 881 transcripts in hippocampus of mouse subjected to 8 and 13 days of chronic social stress procedure. We observed different levels of promoter-specific DNA methylation in the adult stressed individuals in comparison with the non-stressed animals. Genome-wide DNA methylation levels were correlated with gene expression patterns measured by quantitative real-time RT-PCR. A robust and progressive rise in DNA methylation levels across the stress procedure was observed for several loci, typically in conjunction with declining levels of the corresponding mRNAs. These hippocampal differences in DNA methylation and transcriptomic patterns of genes involved in neurodegenerative diseases are consistent with the emerging hypothesis that DNA methylation plays a dynamic, pathophysiological role in the adult brain, and is involved in programming the epigenome in response to chronic stress.

Title: Translocator protein 18kDa occupancy of ONO-2952 in rhesus monkey brain in pet study using ^{11}C-PBR28

Authors: *N. YAMADA[1], K. MITSUI[1], T. SASAMURA[1], S. KATSUMATA[2], S. NAKADE[1]
[1]Discovery Res. Laboratories, ONO Pharmaceut. Co., Ltd., Osaka, Japan; [2]Discovery Res. Alliance, ONO Pharma UK Ltd., London, United Kingdom

Abstract: Translocator protein 18kDa (TSPO) has been proposed to have many physiological functions including regulation of neurosteroids biosynthesis. We have found that ONO-2952, a novel TSPO antagonist, prevented restraint stress-induced defecation at doses of more than 0.3 mg/kg (p.o.) in rats with approximately 50% or more TSPO occupancy in the brain. The aim of this study was to elucidate a correlation between plasma concentration and brain TSPO occupancy of ONO-2952 in conscious rhesus monkeys using ^{11}C-PBR28 as a PET ligand. PET measurements were performed 2 hours and 24 hours after single or multiple oral administration of ONO-2952 at several doses ranging from 0.3 mg/kg to 30 mg/kg. After the head of the test animal was fixed into a stereotactic apparatus, an emission scan (55 frames in 121 min in total) was started simultaneously with the start of intravenous bolus administration of ^{11}C-PBR28. Total distribution volume of ^{11}C-PBR28 was calculated for each region of interest (hippocampus, parietal lobe, frontal lobe, temporal lobe, occipital lobe, corpus striatum, thalamus and cerebellum) by the Logan Plot method. TSPO occupancy was calculated by comparing total distribution volume following ONO-2952 administration with that following vehicle administration. Before ONO-2952 study, a known TSPO antagonist PK11195 was confirmed to occupy TSPO in the monkey brain in PET study using ^{11}C-PBR28, providing that ^{11}C-PBR28 functioned as a PET ligand for TSPO. ONO-2952 was demonstrated to occupy TSPO in the monkey brain. The highest TSPO occupancy rate of ONO-2952 was 94%, suggesting few non-specific binding of ^{11}C-PBR28 in the monkey brain. There was no marked brain region-specificity in the TSPO occupancy of ONO-2952 at any doses. In the evaluation of the relationship between plasma concentration and brain TSPO occupancy of ONO-2952, it was shown that the TSPO occupancy was dependent on the plasma ONO-2952 concentration in individual animal, irrespective of the time from the final dosing. These results indicate that the TSPO occupancy of ONO-2952 in the monkey brain increases up to maximal rate in parallel with its plasma concentration, and ONO-2952 do not accumulate in excessive amounts in the brain. Moreover, these results suggest that ^{11}C-PBR28 is a useful PET ligand to determine the TSPO occupancy by ONO-2952 in the monkey brain and probably in the human brain.

Title: Effects of ONO-2952, a novel translocator protein 18kDa antagonist, on stress-induced rectal hyperalgesia and defecation in rats

Authors: *K. MITSUI[1], T. SASAMURA[1], S. KATSUMATA[2], T. NIWA[1], Y. KAWAHARA[1], N. YAMADA[1], S. NAKADE[1]
[1]Discovery Res. Laboratories, ONO Pharmaceut. Co., Ltd., Osaka, Japan; [2]Discovery Res. Alliance, ONO Pharma UK Ltd., London, United Kingdom

Abstract: Translocator protein 18kDa (TSPO) localized on the outer mitochondrial membrane regulates cholesterol transport from intracellular stores into mitochondria, a rate limiting step of neurosteroidgenesis. It is well known that neurosteroids act as allosteric modulators of excitatory and/or inhibitory neurotransmission and its amount is drastically changed by stress. ONO-2952 is a novel potent and selective TSPO antagonist and we have demonstrated that ONO-2952 inhibited restraint stress-induced pregnenolone production in hippocampus of rats. ONO-2952 thus may have a potential in the treatment of stress-related disorders like irritable bowel syndrome (IBS). The aim of this study was to investigate effects of ONO-2952 on stress-induced disturbance of bowel movement, abdominal pain/discomfort and anxiety-related behavior in rats. To determine effects of ONO-2952 on the bowel movement, weight of feces during 1 hour restraint stress, and relationship between plasma concentration and TSPO occupancy in the brain of ONO-2952 were examined in rats. ONO-2952 or a vehicle was orally administered 2 hours before restraint stress loading. In the experiments of abdominal nociception, ONO-2952 or vehicle was orally administered 1 hour before forelimb restraint stress loading followed by rectal balloon-distension applied at 5 minute interval for 1 hour from 5 minutes after 1 hour stress exposure. The nociceptive threshold was determined by abdominal electromyogram. To examine effects of ONO-2952 on stress-induced anxiety, rats were conditioned 15 times at 1 minute intervals by a 3 second warning beep followed by a 5 second 2 mA foot shock and flash of light. On the following day, rats were again placed in the apparatus 2 hours after oral administration of ONO-2952 or vehicle. Freezing time under the 30 minutes stress without exposure to foot shock was measured. The results showed that ONO-2952 prevented restraint stress-induced defecation at doses of more than 0.3 mg/kg in rats with approximately 50% or more TSPO occupancy in the brain. ONO-2952 also prevented the decrease of visceral nociceptive threshold induced by forelimb restraint stress at doses of 0.3 mg/kg or higher. Moreover, ONO-2952 prevented the freezing behavior induced by conditioned fear stress at doses of 1 mg/kg or higher with an efficacy similar to that of diazepam at 3 mg/kg. These results suggest that ONO-2952 may be useful for the treatment of IBS.

Title: Glucocorticoids orchestrate divergent effects on mood through adult neurogenesis

Authors: *M. L. LEHMANN[1], R. A. BRACHMAN[2], M. HERKENHAM[3]
[1]NIMH, NIH, BETHESDA, MD; [2]Columbia Univ., New York, NY; [3]Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: In mice, both social defeat stress and environmental enrichment (EE) stimulate glucocorticoid (GC) secretion but have opposing effects on hippocampal neurogenesis and mood. HPA-axis dysregulation and decreased neurogenesis are consequences of social defeat. Both outcomes are correlated with depression, but a causal role for either remains elusive. Additionally, enrichment has antidepressant actions that are neurogenesis-dependent, but the contribution of GCs to this effect is unexplored. Thus, for both social defeat and environmental enrichment, how glucocorticoids interact with neurogenesis to change affect remains unknown. Here we explore causal roles of glucocorticoids and neurogenesis in both the induction of depressive-like behavior and its amelioration by EE. By inhibiting neurogenesis and surgically clamping adrenal hormone secretions, we show that neurogenesis_through interactions with the HPA axis_is directly involved in precipitating the depressive phenotype following social defeat. Mice adrenalectomized prior to social defeat showed enhanced behavioral resiliency and increased survival of adult born hippocampal neurons compared to sham-operated mice. The protective effects of adrenalectomy were not conferred to mice with conditional ablation of hippocampal neurogenesis. Additionally, we show that GCs secreted during environmental enrichment promote neurogenesis and are required for the restoration of normal behavior after social defeat. These data demonstrate that glucocorticoid-dependent declines in neurogenesis drive affective disorders following social defeat and that glucocorticoids secreted during

enrichment promote neurogenesis and restore normal behavior after defeat. These data also provide new evidence for the direct involvement of neurogenesis in the etiology of depression, suggesting that treatments promoting neurogenesis will enhance stress resilience.

Title: Effects of unpredictable chronic mild stress in adolescent rats on emotional behavior and hippocampal CREB

Authors: *E. K. ZIMMERMAN[1,2,3], N. PORCH[2,6], J. N. PARRISH[2,4], E. C. DONNY[3,4,5], A. F. SVED[2,4,5], E. THIELS[1,2,3]

Abstract: Unpredictable chronic mild stress (UCMS) is a widely-used model for inducing depressive-like behavior in adult rodents. The ability of UCMS to impact emotional behavior varies across individuals. Work suggests that rats exhibiting low levels of locomotor activity (low responders; LR) during a 2-hr test in a novel open field (OFT) are more sensitive to UCMS than are high responders (HR). Adolescence is a period of heightened vulnerability to stress. We wanted to determine whether UCMS exposure during adolescence has a greater impact on emotional behavior than UCMS exposure during adulthood, and whether the LR/HR dimension is similarly predictive of UCMS effects in adolescents as it is in adults.
First, we tested the effect of a very mild UCMS protocol (vmUCMS) on adult male rats (starting age: >postnatal day 60; pd60). Rats (vmUCMS-exposed rats and controls) were weighed and received sucrose preference tests (SPT) weekly, and were tested in the OFT before and during

week 5 of vmUCMS. Results confirmed that the vmUCMS protocol was sub-optimal for producing significant changes in emotional behavior in adult rats, but that the LR/HR tendencies are persistent, including across the vmUCMS exposure period. We then exposed adolescent rats (starting age: pd28) to vmUCMS or control conditions and assessed the effect on body weight, coat state, and SPT weekly. OFT performance was assessed before and during week 5 of vmUCMS. Elevated plus maze (EPM) performance was examined during week 5, and the rats' brains were collected for measurement of glucocorticoid receptor (GR), CREB, and ERK protein levels in hippocampus and amygdala by Western blot analysis.
Different from the effect in adults, vmUCMS attenuated weight gain, worsened coat appearance, and decreased locomotor activity in the OFT in adolescent rats. Although overall performance on the EPM was unaffected, vmUCMS-exposed adolescent rats either totally avoided open arms or visited them very frequently, whereas control rats exhibited a normal distribution of open arm entries. SPT scores were near ceiling levels in both groups, possibly because of a general high sucrose preference by adolescent rats. Also different from adults, the LR/HR dimension was not stable in adolescent rats, and did not confer differential sensitivity to vmUCMS. Hippocampal GR levels were unaffected by vmUCMS; however, CREB levels tended to be reduced after vmUCMS in adolescence. Additional biochemical analyses are ongoing.
These findings suggest that adolescent rats are more susceptible to vmUCMS than are adult rats, but that susceptibility to vmUCMS among adolescent rats does not vary with differences in locomotor activity in a novel environment.

Title: Sex differences in the effects of acute social defeat in adolescence and in adulthood.

Authors: *S. BHATNAGAR[1], E. VER HOEVE[2], G. KELLY[2], S. LUZ[2], G. BARR[2]
[1]Dept Anesthesiol., Univ. Pennsylvania, Children's Hosp Philadelphia, PHILADELPHIA, PA; [2]Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: Social defeat is a potent stressor for both males and females and females are particularly sensitive to social stressors, especially during adolescence. However, little is known about the impact of social stress in the form of aggression in females either during adolescence or in adulthood. Here, we used the social defeat paradigm (resident-intruder paradigm) in male and female rats in order to investigate their behavior during defeat and their neural activity in response to defeat. Both adolescent and adult male and female rats were subjected to an acute social defeat by a resident lactating female rat. Results indicated that subpopulations emerged in both sexes in which roughly half of the adolescent and adult rats displayed the defeat posture whereas the other half resisted defeat. These differences occurred despite similarly rapid attacks by the lactating resident females. All rats exposed to the lactating female resident showed increases in HPA function as shown through elevated ACTH and corticosterone levels. Furthermore, sex differences in the patterns of neural activity emerged at both ages in the defeat compared to the non-defeat subpopulations. Specifically, males and females showed differences in neural activity within the Insular Cortex, the Paraventricular Nucleus of the Hypothalamus and the Paraventricular Nucleus of the Thalamus. In the prelimbic division of the prefrontal cortex, expression of cytokines, cyclooxygenase-2 and markers for microglia and astrocytes was examined in the female rats. Both defeated and non-defeated intruders showed elevated levels of c-fos, COX-2 and pro-inflammatory cytokines. The level of increase differed between females exhibiting defeat compared to the non defeated females and this effect seemed to be greater in adult compared to adolescent females. Thus, two contrasting patterns of behavior and neuronal activity occurred in response to social aggression in female and male rats and these patterns were different in adolescence compared to adulthood. Furthermore, these patterns of behavior during exposure to the lactating female are associated with variations in expression of pro- and anti-inflammatory cytokines in both adolescent and adult rats. Further study of these variations in responses to social aggression may provide insight into resilience or vulnerability to social stress-associated pathology.

Title: Chronic restraint stress alters the gene expression profile of the hippocampus to a novel, heterotypic stressor

Authors: *J. D. GRAY, T. R. RUBIN, R. G. HUNTER, B. S. MCEWEN
Neuroendocrinology, The Rockefeller Univ., New York, NY

Abstract: Chronic and acute stressors have been linked to a variety of changes in hippocampal function. Both produce changes in gene expression that can endure beyond the discontinuation of stress, though the magnitude and direction of the response varies with stress intensity, duration and predictability. The present studies seek to characterize how changes in the hippocampus resulting from chronic restraint stress (CRS) differentially modulate gene expression in response to a novel, acute stressor. Male c57/bl6 mice were subjected to 1) a forced swim test (FST), 2) CRS for 21 days and then a FST, or 3) allowed to recover 21 days after CRS and subjected to FST. mRNA from the hippocampus of each animal was extracted and used to generate a cDNA library for hybridization to Illumina MouseRef8-v2 microarray. Changes in gene expression were compared against cDNA from the hippocampus of age-matched controls that were not subjected to any stress. Hybridization data was analyzed for statistical significance using a series of pairwise comparisons to identify genes differentially expressed across conditions. 1,369 genes were identified with significantly altered expression levels ($p < .05$) in mice subjected to FST, 4,448 genes were significantly changed in mice subjected to FST at the end of CRS, and 1,291 genes were significantly different in mice subjected to FST after recovery from CRS. Across comparisons, 104 genes reached significance in all FST conditions. Pathway analysis identified significant clusters of differentially expressed genes. Several pathways were significantly altered across conditions, principally that of Nf-kB. RT-PCR was performed to validate changes identified by the arrays in genes established as responsive to an acute stress. The immediate early gene, cFos, was found to be comparably increased on the array and by RT-PCR after FST, indicating the arrays are reliable indicators of changes in mRNA levels. The large number of genes changed in FST immediately after CRS, which minimally overlap with the naïve FST condition (only 9.2% of genes), suggests that CRS uniquely alters how cells in the hippocampus respond to a novel stressor. Mice allowed to recover from CRS and subjected to FST shared 14.0% of the significantly different genes with naïve FST mice, and 34.7% of genes with mice subjected to FST after CRS. This suggests that even after recovery, mice with a stress history have a more similar hippocampal response then naïve mice to a novel stressor. Ongoing analysis of the genes identified will provide new insight in the molecular mechanism underlying the stress response in the hippocampus.

Title: Chronic corticosterone sensitizes the mesolimbic dopamine reward pathway to excitatory NMDA receptor activity

Authors: *J. N. BERRY, L. J. SHARRETT-FIELD, A. R. REYNOLDS, M. A. PRENDERGAST
Psychology, Univ. of Kentucky, Lexington, KY

Abstract: Elevations in circulating corticosteroids during periods of stress may influence activity of the mesolimbic dopamine reward pathway, which plays a crucial role in drug dependence, and compromise neuronal viability, possibly by increasing glutamatergic *N*-methyl-D-aspartate (NMDA) receptor expression and/or function in a glucocorticoid receptor-dependent manner. The current study used organotypic co-cultures of the ventral tegmental area and nucleus accumbens designed to mimic the mesolimbic pathway *in vitro* and examined effects of chronic pre-exposure to corticosterone on NMDA receptor-mediated cell death. Co-cultures were pre-exposed to corticosterone (1 μM) or vehicle for 5 days prior to 24 hour co-exposure to NMDA (200 μM). Chronic pre-exposure to a non-toxic, but stress-relevant, concentration of corticosterone significantly enhanced subsequent NMDA-induced neuronal toxicity in the ventral tegmental area as indicated by increased propidium iodide uptake. The effect of corticosterone pre-exposure on subsequent NMDA-induced neurotoxicity in the ventral tegmental area was NMDA receptor dependent, as co-exposure to the selective NMDA receptor antagonist 2-amino-7-phosphonovaleric acid (APV) attenuated the observed neurotoxicity. In contrast, no significant effects were observed in the nucleus accumbens. These results suggest an enhancement of NMDA receptor systems or downstream effectors in areas of the mesolimbic reward pathway following chronic pre-exposure to corticosterone, which leads to enhanced neuronal vulnerability to future excitotoxic insults. This may be of critical importance as use of psychostimulants and other drugs of abuse may produce excitotoxic events in these areas, thus further compromising neuronal viability.

Title: Chronic non-invasive disruption of the hypothalamic-pituitary-adrenal stress axis has effects on learning and memory.

Authors: C. D. WILSON[1], B. S. MCEWEN[1], *I. N. KARATSOREOS[2]
[1]Neuroendocrinology, The Rockefeller Univ., New York, NY; [2]VCAPP, Washington State Univ., Pullman, WA

Abstract: Stress is an inescapable reality of modern life. The physiological and behavioral responses that underlie the stress system are based in systems that evolved to protect an organism from threats to homeostasis, such as predation, agonistic encounters with conspecifics, or changes in the environment. In humans, disruption of the hypothalamic-pituitary-adrenal (HPA) axis (the neuroendocrine system central in the stress response) is associated with numerous neuropsychiatric conditions, as diverse as depression, anxiety, post-traumatic stress disorder, and is clearly observed during aging. As such, understanding how a disrupted HPA axis affects neural circuits underlying emotionality and cognition is of key importance.
The purpose of our study was to investigate the behavioral and neural effects of a disrupted HPA axis on spatial and emotional learning systems, both of which are affected by chronic stress. We have characterized a model of chronic reversible HPA disruption induced by non-invasively delivering adrenal stress hormone corticosterone (CORT) in the drinking water of male C57 mice for 28d. This treatment suppresses function of the HPA axis, including eliminating endogenous hormonal responses to stress. Under this model, CORT levels follow a diurnal rhythm, as the animals consume most of their fluids in early night. This results in peak plasma CORT value of around 100ng/ml a few hours after the start of dark phase as opposed to the naturally occurring peak of 60-70ng/ml at the start of the dark phase. As such, this unique treatment results in almost complete inhibition of the endogenous HPA axis, but rhythmic plasma CORT, a situation that is not possible with adrenalectomy and/or pellet or mini-pump experiments. It also avoids the inherent issues involved with daily CORT injections. We found that this treatment results in impaired learning and memory in the Morris Water Maze, a hippocampal based learning and memory task, but no apparent differences in a contextual fear conditioning, a task that also engages the amygdala. This suggests that our model of HPA

disruption may affect aspects of spatial cognition but not certain types of emotional learning. Further studies to explore specific neural changes in the hippocampus and amygdala after chronic HPA disruption are necessary to fully understand the mechanisms by which our model impairs behavioral function.

Title: Increased EPO level, but decreased VEGF expression and microvascular density in chronic moderate hyperoxia in the mouse cerebral cortex

Authors: *J. C. LAMANNA[1], G. F. BENDERRO[2]
[1]Dept. of Physiol. & Biophysics, Case Western Reserve Univ. Sch. Med., CLEVELAND, OH; [2]Anat., Case Western Reserve Univ., Cleveland, OH

Abstract: The partial pressure of oxygen in the brain parenchyma is tightly controlled, and normal brain function is delicately sensitive to continuous and controlled oxygen delivery. Chronic moderate hypoxia leads to angiogenesis, suggesting a modulatory role for oxygen in determining capillary density. The objective of this study was to determine physiologic and brain angiogenic adaptational changes during chronic moderate normobaric hyperoxia in mice. Four-month old C56BL/6J mice were kept in a normobaric chamber at 50% O_2 for up to 3 weeks. Normoxic littermates were kept in the same room outside the chamber. Freshly collected or fixed brain specimens were analyzed by RT-PCR, Western blot analysis and immunohistochemistry. Results show accumulation of hypoxia inducible factors 1 and 2 (HIF-1 and 2), and increased expression of erythropoietin (EPO), cyclooxygenase-2 (COX-2) and angiopoietin-2 (Ang-2). Conversely, vascular endothelial growth factor (VEGF), and VEGF receptor-2 (KDR/Flk-1), Peroxisome proliferator-activated receptor gamma coactivator 1-α (PGC-1) and prolylhydroxylase-2 (PHD-2) expressions were decreased. VEGF mRNA level was diminished but there was no change in HIF-1 mRNA and von Hippel Lindau E3 ubiquitin ligase (VHL) protein expression. Microvascular density was significantly diminished by the end of the 3rd week of hyperoxia. Overall, our results are: 1) increased expression of the potent neuroprotective molecule, EPO; 2) diminished expression of the potent angiogenic factor, VEGF; and 3)

decreased microvascular density. We can, therefore, conclude that brain microvascular density can be controlled by HIF-independent mechanisms, and that brain capillary density is a continuously adjusted variable with tissue oxygen availability as one of the controlling modulators.

Title: The glutamate dysfunction in the stressed tripartite synapse

Authors: *C. NASCA[1,2], T. R. RUBIN[1], J. D. GRAY[1], A. PITTALUGA[3], F. NICOLETTI[2,4], B. S. MCEWEN[1]
[1]Neuroendocrinology, Rockefeller Univ., New York, NY; [2]Physiol. and Pharmacol., Sapienza Univ., Rome, Italy; [3]Exptl. Med., Ctr. of Excellence for Biomed. Research, Univ. of Genoa, Genoa, Italy; [4]INM Neuromed, Pozzilli, Italy

Abstract: Vulnerability to stress is a cardinal feature of many psychiatric disorders. Growing evidence indicates that both stress and psychiatric disorders are associated with epigenetic modifications and atrophy and loss of neurons and glia, which contribute to the decreased size and function of limbic brain regions that are involved in the pathophysiology of mood disorders, such as the hippocampus and prefrontal cortex. We hypothesized that glutamatergic dysfunction associated with stress-related disorders could involve changes in the expression of the catalytic subunit (Xc-) of the glutamate cystine antiporter, which supplies extrasynaptic glutamate, thereby regulating the endogenous activation of extrasynaptic receptors, such as presynaptic mGlu2/3 receptors, and postsynaptic mGlu5 and NR2B-containing NMDA receptors. We found that acute exposure to restraint stress in mice caused a substantial reduction in the transcripts encoding for Xc-, mGlu2, mGlu3, and mGlu5 receptors, and the glial high affinity glutamate transporter, GLT-1, in the hippocampus with no changes in any of these transcripts in the prefrontal cortex. Interestingly, in mice exposed to chronic stress in the form of restraint stress or a chronic oral administration of corticosterone, we found reductions in Xc-, mGlu2, mGlu3, and mGlu5 receptors, and GLT-1 mRNA levels in the prefrontal cortex, but not in the hippocampus.

Moreover, these data seem to be correlated to an in progress gene array analysis. We conclude that stress causes adaptive changes in the expression of glutamate transporters and mGlu receptors that sequentially involves the hippocampus and the prefrontal cortex. Unraveling the nature of these changes might pave the way to novel therapeutic interventions for stress-related disorders.

Title: Afferent corticotropin releasing factor (crf) projections to the nucleus accumbens.

Authors: K. E. TSCHETTER[1,3], *L. B. CALLAHAN[4,3], P. J. RONAN[5,2,3]
[1]Basic Biomed. Sci., Univ. of South Dakota Sanford Sch. of Med., Vermillion, SD; [2]Psychiatry, Univ. of South Dakota Sanford Sch. of Med., Sioux Falls SD, SD; [3]VA Res. Service, Sioux Falls, SD; [4]Avera McKennan, SIOUX FALLS, SD; [5]AveraResearch Inst., Sioux Falls, SD

Abstract: Stress is a major factor leading to both drug use and relapse. Common neurobiological substrates and pathways underlie actions of both drugs of abuse as well as stress. One such substrate is the neuropeptide corticotropin-releasing factor (CRF); a major coordinator of endocrine, autonomic and behavioral output to stress. In animal models, CRF has been directly implicated in mediating both stress-induced reinstatement of drug-seeking behavior as well as the anxiety associated with withdrawal. Dopaminergic projections from the midbrain ventral tegmental area (VTA) to the nucleus accumbens (NAc) and other forebrain structures are particularly significant components of the reward pathway. We have previously shown that dopamine cells of the VTA express CRF1 receptors and others have shown that the VTA receives afferent CRF fibers from cells of the PVN, CeA and BNST. Until now, the sources of afferent CRF pathways to NAc have been unknown. The purpose of this study was to determine these pathways and further characterize the expression of components of the CRF family (CRF, CRF_1 receptors, CRF_2 receptors, and corticotropin releasing factor binding protein; CRF-BP) in

these regions. Using a combination of retrograde tracer, immunohistochemistry and confocal microscopy techniques we found clear evidence for CRF innervation of NAc shell from CRF cells originating primarily from the CeA and PVN with a lesser contribution from cells of the BNST. Additionally, we provide many details of specific expression of CRF system components within the VTA-NAc pathway. This is the first study to provide clear evidence of direct CRF innervation of the NAc. This study adds weight to the notion that regions that the CeA, PVN and BNST should be considered part of an extended brain reward/reinforcement system.

Title: The role of stress-induced ghrelin elevations in hippocampal neurogenesis: implications for the regulation of mood and food reward behavior

Authors: *A. WALKER[1,2], S. OSBORNE-LAWRENCE[2], J.-C. CHUANG[2], J. M. ZIGMAN[2]
[1]Dallas, TX; [2]Intrnl. Medicince (Division of Hypothalamic Research), Univ. of Texas Southwestern, Dallas, TX

Abstract: Many studies show a correlation between psychosocial stress, depression, and obesity, although mechanisms linking these disease states have yet to be fully elucidated. Mouse models to investigate these mechanisms include the chronic social defeat stress (CSDS) protocol, which induces both depressive-like behavior and enhanced reward-based, hedonic eating behavior. Of interest, CSDS and other forms of stress raise circulating levels of ghrelin, a stomach-derived orexigenic peptide hormone which possesses antidepressant-like actions and mediates reward-based behaviors of various types. Mice lacking the ability to respond to CSDS-induced ghrelin elevations (GHSR-null mice) display an increase in depressive-like behavior and a loss of food-reward behavior as compared to similarly CSDS-exposed wild-type littermates. The brain region(s) and mechanisms through which ghrelin may be acting to have these behavioral effects

remain mostly unknown. Since it is well-established that chronic stress reduces neurogenesis and cell survival in the hippocampal dentate gyrus (DG) of wild-type mice, that ghrelin receptors are expressed in the hippocampus, and that ghrelin has neuroproliferative and neuroprotective properties, we focused here on determining the role of altered hippocampal neurogenesis in the behavioral differences observed between GHSR-null and wild-type littermates upon stress. Using Western blot analyses, DG expression of pERK, pCREB, and BDNF - all signaling molecules involved in cell growth and survival -- was shown to be significantly lower in CSDS-exposed GHSR-null mice as compared to CSDS-exposed wild-type littermates. Using immunohistochemisty, the number of proliferating (Ki67-immunoreactive) cells in the DG of CSDS-exposed GHSR-null mice was shown to be significantly reduced as compared to CSDS-exposed wild-type littermates. In contrast, the number of apoptotic (caspase 3-immunoreactive) cells in the DG of CSDS-exposed GHSR-null mice was significantly elevated as compared to CSDS-exposed wild-type littermates. The overall reduction of neurogenesis in stressed GHSR-null mice correlated with the increase in depressive-like behavior as well as loss of food reward behavior observed in these mice. Therefore, these data suggest that ghrelin may modulate mood and food reward behavior upon stress through its regulation of neurogenesis in the DG.

Title: Enhanced ethanol voluntary intake and decreased hippocampal neuronal excitability in c57bl/6j mice exposed to post-weaning social isolation

Authors: *E. SANNA[1,2], G. TALANI[1], V. LICHERI[1], F. CANNAS[1], S. LUTZU[1], T. FANUTZA[1], F. TRUDU[1], N. MASALA[1], G. BIGGIO[1,2]
[1]Dept Life and Envrn. Sci., Univ. Cagliari, Monserrato 09042, Italy; [2]C.n.r., Inst. of Neurosci., Cagliari, Italy

Abstract: Exposure early in life to stressful experiences is considered a critical factor for an increased vulnerability, during adulthood, to development of psychiatric disorders, including abuse of psychotropic substances such as alcohol. Rearing rodents in isolation (SI), starting at the

time of weaning and lasting several weeks, is a valuable model of chronic stress by which to examine the neurobiological and neuroendocrine mechanisms involved in the interaction between early stress and alcohol abuse. Our previous work has shown that post-weaning SI in C57BL/6J mice is associated with a decreased plasma and brain levels of neuroactive steroids, and a parallel up-regulation of extrasynaptic GABA-A receptors in dentate gyrus granule cells (DGGCs). These changes are accompanied by an enhanced voluntary intake of ethanol in the free-choice drinking paradigm compared to group-housed (GH) animals. Furthermore, we also demonstrated that SI significantly reduced long-term synaptic plasticity in CA1 pyramidal cells and ethanol was more effective in inhibiting LTP in SI than GH mice. More recently, current-clamp analysis of DGGCs revealed a decrease in resting membrane potential, membrane input resistance, and firing of action potentials in SI compared to GH mice, suggesting that SI results in a reduced level of neuronal excitability in DGGCs. Since daily administration of progesterone during the 6-weeks of isolation period reverts the effects caused by SI on tonic current and neuronal excitability in DGGCs, it likely that the changes induced by SI may be triggered, at least in part, by the decrease of plasma and brain levels of neuroactive steroid. This effect, in turn, may drive the up-regulation of extrasynaptic GABA-A receptors in DGGCs, and consequently the reduced excitability of the whole hippocampal excitatory circuitry.

Title: The influences of reproductive status and acute stress on the levels of phosphorylated delta opioid receptor immunoreactivity in rat hippocampus

Authors: *S. R. BURSTEIN[1], T. J. WILLIAMS[1,2], D. A. LANE[1], M. G. KNUDSEN[1], V. M. PICKEL[1], B. S. MCEWEN[3], E. M. WATERS[3], T. A. MILNER[1,3]

Abstract: Ovarian hormones and stress influence the hippocampal opioid system, which plays an important role in learning. Acute immobilization stress (AIS) differentially alters the level of phosphorylated mu opioid receptors in the hippocampus of males and females, which may contribute to reported sex differences in the hippocampally-dependent behavior of stressed animals. As ovarian hormones can alter the trafficking of delta opioid receptors (DORs) in addition to mu opioid receptors, we assessed the interactions of gonadal hormones and AIS on the activation of DORs in the hippocampus of male and female rats using a well-characterized antibody to the phosphorylated DOR at the SER363 carboxy-terminal residue (pDOR; Cell Signaling). First, the distribution of pDOR-immunoreactivity (ir) was determined using light and electron microscopy. Light microscopy showed pDOR-ir predominantly located in apical dendrites in the CA1-3 layers, especially in the CA2/CA3a region. pDOR-ir also was seen in interneuron somata and dendrites in stratum oriens of CA1-3 and the hilus of the dentate gyrus. At the subcellular level, pDOR-ir was primarily located in postsynaptic profiles in association with dendritic spines and endomembranes within dendrites. Rarely, pDOR-ir was found in axons and terminals. The cellular distribution of the pDOR is consistent with that of DORs (Williams et al., 2011 PMC3045654) and strategically places the pDOR for modulating neurons known to be involved in stress responses. Second, pDOR-ir level was characterized using quantitative light microscopic densitometry. To investigate opiate activation of DORs, the level of pDOR-ir was examined in male rats one hour after a single morphine injection (20mg/kg, I.P.). We found a significant increase in pDOR-ir level in the CA2/CA3a region of male rats exposed to morphine in comparison to controls, confirming morphine activation of DORs. Next, we determined if pDOR-ir level was altered by hormone status and/or in response to AIS. In unstressed rats, the level of pDOR-ir in stratum radiatum of CA2/CA3a was increased in estrus (elevated estrogen and progesterone) females compared to proestrus and diestrus females and males. However, immediately following 30 minutes of AIS, no significant differences in pDOR-ir level were seen across estrous cycle phase or sex. These findings suggest that levels of activated DORs vary with estrous cycle phase and that acute stress may dampen the differential effects on DOR activation in females.

Title: Effects of ethanol on nucleus accumbens monoamine levels in socially isolated and group housed rats

Authors: *A. KARKHANIS, J. LOCKE, J. L. WEINER, S. R. JONES
Wake Forest Sch. of Med., Winston-Salem, NC

Abstract: Exposure to adverse experiences such as social isolation for an extended period of time during childhood results in chronic stress; which often results in psychiatric problems such as anxiety and affective disorders, and increased probability of drug and alcohol abuse problems. Chronic stress alters the normal development of monoamine systems, affecting adult behavior. Behavioral differences in isolation and group reared rats suggest that there are alterations in the limbic system. Isolation rearing affects appetitive behavior during ethanol (EtOH) self-administration; isolated rats have a greater preference for EtOH than group reared rats. However, to our knowledge no studies have examined the effects of acute EtOH on monoamine levels in group and isolation reared rats. Previous studies have shown that acute EtOH results in increased extracellular dopamine (DA) levels in the nucleus accumbens (NAc), and intraperitoneal (i.p.) administration of amphetamine results in significantly larger DA increases in isolated than in group housed rats. Thus, we hypothesized that increase in levels of DA would be greater in isolated rats compared to group reared rats following EtOH administration.
In the current study, male Long Evans rats were either group reared (groups of 4) or isolation reared beginning on postnatal day 28 for 6 weeks, followed by an assessment of anxiety-like behavior. Following behavioral testing, in vivo microdialysis was conducted to measure NAc monoamine levels in freely moving group and isolation reared rats. Rats were challenged with acute (i.p.) administration of EtOH (1 g/kg). Brain samples were collected every 20 min and extracellular levels of DA, norepinephrine (NE), and serotonin (5-HT) were quantified using High Performance Liquid Chromatography.
Isolation reared rats were observed to have increased levels of DA at baseline compared to group

reared rats. Interestingly, although DA levels in both groups increased, the increase in isolation reared rats was significantly smaller than in group reared rats. Moreover, the DA response to EtOH was temporally delayed in isolation reared rats. Levels of NE were lower in isolated rats; EtOH resulted in an increase in NE levels in both groups, albeit a temporal delay was observed in isolation reared rats. No difference was observed in levels of 5-HT at baseline. Preliminary data show extracellular levels of 5-HT decreased in both groups following EtOH challenge. Thus, we show that DA, NE, and 5-HT in the NAc differentially respond to acute EtOH in isolated and group reared rats. Such changes may be involved in the documented increases in anxiety-like and drinking behaviors in isolated rats.

Title: Effects of varying timelines of restraint stress on neuroplasticity.

Authors: J. J. HANNA[1,2], K. SAINZ[2], C. D. CONRAD[1], *D. P. BALUCH[2]
[1]Psychology, [2]Sch. of Life Sci., Arizona State Univ., Tempe, AZ

Abstract: Stress influences neurogenesis in the hippocampus and modifies the structure/volumes of the hippocampus and medial prefrontal cortex (mPFC), regions involved in executive function and memory. It has been suggested that that chronic stress and these resulting morphological changes may contribute to neurological disorders, such as depression and post-traumatic stress disorder. Several chronic stress studies reveal that the morphological alterations, such as dendritic retraction in the CA3 region of the hippocampus, occur over weeks (i.e., 21 days and not 10 days). To date, no study has documented a thorough timeline of various metrics of neuronal plasticity as they might emerge early in the stress experience in both the hippocampus and mPFC. In this study, we examined the effects of restraint stress at various durations on neurogenesis and dendritic arbor morphology in mice within the hippocampus and mPFC. Wild type C57BL/6J mice were placed in Plexiglas restraints for various time periods over a duration of 2-21 days (1 hour for 2 days, 0.5 hour for 5 days, 1 hour for 5 days, and 5 hours for 21 days). Non-stressed controls were either left alone with food and water or yoked to a respective restraint stress group with their food and water removed. Metrics of neuroplasticity in the

hippocampal CA3 region and in the mPFC (prelimbic and cingulate) at level II-III, included measuring neurogenesis, identified using BrdU, functional activation of the immediate early gene product, FOS, using immuno-fluorescence, and changes in dendritic complexity of pyramidal apical dendrites as determined from Golgi stained sections. The results are expected to show that the hippocampus and mPFC would express different timelines for neuroplastic changes and that stress-induced changes in neurogenesis and FOS would precede dendritic remodeling.

Title: Triggering the epigenome to combat stress: Modulation of depressive symptoms in adult rats by prenatal choline supplementation

Authors: *K. ERICKSON, D. WISE, M. ROSENGREN, M. J. GLENN
Colby Col., Waterville, ME

Abstract: Availability of the nutrient choline in early development has lasting effects on neural function and behavior. Prenatal choline supplementation in rats exerts marked neuroprotective effects against severe disorders such as fetal alcohol syndrome and epilepsy; it also prevents age-related declines in plasticity and cognitive function. Choline levels may exert neuroprotective effects by increasing adult neural plasticity and neurotrophic expression, possibly via epigenetic effects on gene regulation. Interestingly, a failure in neural plasticity and diminished neurotrophic expression are believed to be important contributors to the pathology associated with depression. Recent work in our lab (Glenn et al., 2012) compellingly showed that choline supplementation early in life has an antidepressant effect in adult female rats. The aim of the present study was to extend these findings to both male and female rats, as depression in humans affects males and females differently, and to examine both prenatal choline supplementation and deficiency, as prenatal choline deficiency in rats may lead to vulnerability to pathology such as depression. This study also investigated the effects of prenatal choline availability and chronic

stress on the epigenome as a possible mechanism for antidepressant properties of choline supplementation. From gestation day 10 until birth, pregnant Sprague Dawley rat dams were fed either deficient (0 g/kg choline), standard (1.1g/kg choline) or supplemented (5 g/kg choline) diets. Offspring, who served as subjects in the study, were cross-fostered and weaned on postnatal day 25 and fed a standard diet for the remainder of the study. In adolescence, the open field test was used to gauge activity and anxiety based on diet condition. As adults (approximately 120 days of age), half of the rats from each diet condition underwent 14 days of chronic variable stress (CVS), a widely used method for inducing depression-like symptoms in rats; the other half of each group were handled normally and not stressed. Following CVS, rats were assessed for emotional reactivity: the open field test, the elevated plus maze and the forced swim test. Rats were sacrificed and brains extracted to look for neurogenesis and epigenetic changes. The open field and elevated plus maze revealed that choline deficient males and females were more anxious and vulnerable to stress. Choline supplemented males also displayed increased anxiety, although choline supplemented females did not. A histone acetylation assay revealed that stressed, supplemented females had increased histone acetylation, a feature associated with antidepressants.

Title: Distribution of corticosteroid binding globulin and glucocorticoid receptors in rat hippocampus

Authors: *J. D. CALDWELL[1], E. SIVUKHINA[2], G. F. JIRIKOWSKI[2]
[1]Pharmacol., Lake Erie Col. Oesteopathic Med., ERIE, PA; [2]Anat., Univ. of Jena, Jena, Germany

Abstract: Adrenal steroid hormones are known to be involved in central stress responses. They are thought to act through nuclear glucocorticoid receptors (GR), which have been described in various brain regions, including the hippocampus. Recently we observed the intrinsic expression of corticosteroid binding globulin (CBG) in various brain regions. Here we examined the immunocytochemical co-localization of CBG and GR in the rat hippocampus. While nuclear GR staining was found in most of the pyramidal cells in the CA 1 region and in the dentate gyrus, the CA 2 and the CA 3 regions were almost devoid of GR. Intense cytoplasmic immunofluorescence

for CBG was found in the CA 2 and CA 3 regions while CBG appeared in the CA 1 region predominantly in non-pyramidal cells. Co-localization of both antigens was most pronounced in the subiculum and in the dentate gyrus. We conclude that glucocorticoids act on the limbic system through both nuclear receptors and non-genomic effects mediated by CBG and its putative membrane receptor.

Title: Glucocorticoid receptors in the prefrontal cortex mediate stress-evoked dopamine release via descending glutamatergic input to the ventral tegmental area

Authors: *K. A. BUTTS, A. G. PHILLIPS
Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Enhanced dopamine release in the medial prefrontal cortex (mPFC) is a well-documented response to acute stress. We have previously shown that glucocorticoid receptors in the mPFC regulate stress-evoked dopamine release (Butts et al., 2011) but the underlying mechanism(s) is unknown. Dopamine neurons in the ventral tegmental area (VTA) receive excitatory input from and send reciprocal projections to the mPFC (Sesack and Carr, 2002). We hypothesized that blockade of prefrontal glucocorticoid receptors could reduce activity of descending glutamatergic input to the VTA, thereby attenuating stress-evoked dopamine release in the mPFC. We also examined the possible role of glucocorticoid-induced synthesis and release of endocannabinoids acting presynaptically via cannabinoid CB_1 receptors to inhibit GABA release onto prefrontal pyramidal cells (Hill et al., 2011), thus enhancing descending glutamatergic input to the VTA during stress. *In vivo* microdialysis was performed in freely-moving rats subjected to an acute tail-pinch stress. A glucocorticoid receptor antagonist or a cannabinoid CB_1 receptor antagonist was delivered by reverse-dialysis into the mPFC, while glutamate and dopamine was continuously sampled from the VTA or mPFC. Glutamate and dopamine in microdialysates were separated by high-pressure liquid chromatography and quantified by electrochemical detection. We demonstrate that acute tail-pinch stress leads to a significant increase in glutamate release in the VTA but not in the mPFC. Glucocorticoid

receptor blockade in the mPFC significantly attenuated the stress-evoked glutamate release in the VTA. In contrast, administration of the cannabinoid CB_1 receptor antagonist into the mPFC failed to attenuate stress-evoked dopamine release in the mPFC. Taken together, our data suggest that glucocorticoids act locally within the mPFC to modulate mesocortical dopamine release by potentiation of glutamatergic drive onto dopamine neurons in the VTA.

Title: Cooperativity of corticosteriods and norepineprhine in non-genomic modulation of corticocortical transmission

Authors: A. K. PETKO, E. WHITE, *D. M. SENSEMAN
Biol., Univ. of Texas At San Antonio, San Antonio, TX

Abstract: In a variety of mammalian and non-mammalian species, increased levels of corticosteroids trigger overt changes in behavior (e.g. increased locomotion) over time scales too short to involve *de novo* protein synthesis. Recently, several electrophysiological studies of rat brain slices have led to a rapid increase in our understanding of how such non-genomic effects of corticosteroids modulate neurotransmitter release . What remains to be determined, however, is how these modulatory effects lead to alterations in the organization and activities of neuronal ensembles that underlie overt behavioral changes. The isolated, *in vitro*, turtle telencephalon provides an especially amenable preparation in which to study non-genomic corticosteroid actions on neuronal assemblies. Since the preparation is basically a flat sheet with its excitatory and inhibitory interconnections largely intact, both whole-cell recording of individual cortical, hippocampal, and septal neurons can be combined with simultaneous monitoring of population activity using voltage-sensitive dye imaging (VSDI). As a first step to developing this promising preparation, we monitored the local field potential (LFP) evoked in the turtle's homologue of hippocampal area CA3 (i.e. dorsomedial cortex) in response to brief electrical stimulation of the turtle's homologue of the dentate gyrus (medial cortex). The waveforms of these LFP's were complex with multiple positive and negative peaks indicating activation of several polysynaptic pathways (see fig below). We found that in most preparations, the LFP waveform in the

homologue of CA3 could be reversibly altered (arrow in fig) by bath application of 20 microM norepinephrine (NE) and 10 microM dexamethasone (DEX). (Comparatively high levels of DEX mostly likely reflect its difficulty in crossing the semi-intact blood brain barrier). Significantly, similar effects were not observed when either drug was applied individual, but only when both drugs were applied in combination.

Title: Prenatal stress in rats alters hippocampal nicotinic acetylcholine receptor levels in adult offspring

Authors: *M. B. BURKE[1,2], K. M. SCHULZ[2,4], K. M. ANDRUD[2,4], J. N. PEARSON[3], A. KREISLER[5], C. E. ADAMS[2,4], S. LEONARD[2,4], K. E. STEVENS[2,4]

[1]Univ. of Colorado Denver, Denver, CO; [2]Dept. of Psychiatry, [3]Neurosci. Program, Univ. of Colorado Anschutz Med. Campus, Aurora, CO; [4]VAMC, Denver, CO; [5]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Prenatal stress in humans is associated with psychiatric problems in offspring such as anxiety, depression, and schizophrenia. These same illnesses are also associated with neuronal nicotinic receptor abnormalities. Despite the known associations between prenatal stress exposure and offspring mental illness, and between mental illness and nicotinic receptor abnormalities, it is not known whether prenatal stress exposure impacts neuronal nicotinic receptors. Thus, we tested the hypothesis that maternal stress alters the development of hippocampal alpha4 beta2 and alpha7 nicotinic acetylcholine receptor levels in offspring. Female Sprague-Dawley rats experienced unpredictable variable stressors 2-3 times daily during the last week of gestation. At weaning (21d) the offspring were assigned to same-sex prenatally stressed or nonstressed groups. In adulthood, offspring brains were collected and processed for quantitative autoradiography using an 125I-epibatidine (alpha4 beta2 nicotinic receptor-selective), and 125I-alpha-bungarotoxin (alpha7 nicotinic receptor selective) ligands. We found that prenatal stress significantly increases epibatidine binding in the offspring's alveus, CA1 lacunosum moleculare, CA3 laconusum moleculare, and the dentate gyrus molecular layer, suggesting that prenatal stress significantly increases hippocampal alpha4 beta2 receptor levels. No effects of stress or interactions between sex and stress were observed for epibatidine binding. We are also currently quantifying hippocampal alpha-bungarotoxin binding to determine whether prenatal stress exposure differentially impacts alpha7 and alpha4 beta2 nicotinic receptor subtypes, or whether the effects of prenatal stress exposure are limited to the alpha4 beta2 nicotinic receptor subtype. Taken together, our results suggest that nicotinic receptors may be an important link between prenatal stress exposure and risk for neuropsychiatric illness.

Title: Chronic exposure to environmental noise stress in early life produces long-term improvement in the rat spatial learning

Authors: *O. HUET[1], Y. RUVALCABA-DELGADILLO[1], R. GONZÁLEZ-CASTAÑEDA[1], G. CHIPRES-TINAJER[1], P. HERNÁNDEZ-CARRILLO[1], G. YAÑEZ-DELGADILLO[1], J. GARCÍA-ESTRADA[3], S. LUQUIN[1], F. JÁUREGUI-HUERTA[2]
[1]Univ. De Guadalajara, Zapopan, Mexico; [2]Univ. De Guadalajara, Guadalajara, Mexico; [3]Inst. Mexicano del Seguro Social, Guadalajara, Mexico

Abstract: There is a growing concern that the excess environmental noise experienced by infants may disrupt their growth and development, putting them at risk for cognitive and neurological alterations. In the present experiment, we used the Morris Water Maze to assess short and long-term spatial learning changes in juvenile rats exposed to environmental noise. Recently weaned male Wistar rats were subjected to chronic environmental noise (urban sounds adapted to the rat audiogram) during the 15 days after weaning (from 21-36 posnatal days). Then, Morris Water Maze was used to evaluate the rat spatial learning performance both, at the end of the noise exposure (36 posnatal day) and two months later when the rat was adult. In addition, body weight measures were taked periodically. Our results, shows that the environmental noise exposed rats exhibit a retardation in their body weight gain. However, Morris Water Maze assessment revealed no impairment in spatial learning abilities but a remarkable improvement in those who were exposed to environmental noise. Exposed rats performed better both, at the end of the exposition when they where youngs, and two months later when they were adults. Such results suggest that our noise model works as a moderate stressor which indeed stimulate spatial learning abilities. Such effect persisted long after the noise protocol was concluded.

Abstract: For several reasons, such as easy maintenance, rapid generation times, and increasingly mapped genomes, teleost fishes are emerging as an alternative to small mammals in biomedical, neural, and behavioral research. Behavioral, genetic, and physiological screening of high numbers of individuals across treatments and generations is one particularly attractive feature of fish model systems. Both animal welfare considerations and fundamental scientific questions regarding the evolution of learning and memory have directed particular attention towards possible cognitive and emotional processes in fishes. Here we show that the omission of expected reward (OER) leads to increased aggression towards conspecifics in classically conditioned Atlantic salmon (*Salmo salar*). Furthermore, in response to an acute stressor, OER fish displayed increased dopaminergic (DA) neurotransmission compared to controls. There was also a general downregulation of dopamine receptor D1 gene expression in the telencephalon of OER groups, which suggests a coping mechanism in response to unbalanced DA metabolism. These results indicate that animals subjected to unpredictable reward conditions develop a senzitation of the DA signalling system, manifest as a potentiated response to novel, stressful stimuli. Similarities between fish and mammals in this response to unpredictability illustrates a role for teleost fish as models to understand the development of different types of DA dysfunction.

Title: Serotonergic mechanisms underlying sex differences in habituation to repeated restraint stress

Authors: *N. GOEL, Q. ZHENG, L. QIU, V. VIAU
Cell. and Physiological Sci., Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Maladaptive stress coping is associated with increased risk of affective disorders such as depression and anxiety. These disorders are more prevalent in women than in men and involve dysfunction of both the serotonin (5-hydroxytryptamine, 5-HT) system and the hypothalamic-pituitary-adrenal (HPA) stress axis. We hypothesized that the ability of the HPA axis to adapt to repeated stress differs in males and females and that habituation of stress hormone secretion is associated with changes in serotonergic markers. To investigate sex differences in stress habituation, we exposed adult male and female rats to 10 daily episodes of 3 hour restraint stress. ACTH responses in males declined significantly by the 5th day of restraint compared to the first day. At day 10, ACTH levels were further decreased by a small degree. In contrast, ACTH responses in females did not show a significant decline, even by the 10th day of repeated stress. Similarly, restraint-induced corticosterone levels in males were attenuated by day 5, while females did not display a significant reduction on day 5 or 10. These data indicate that the capacity to habituate to repeated stress is impaired in females. A potential mediator of HPA axis function and changes in mood is the 5-HT 1A receptor, which has been implicated in previous studies of chronic stress and depression. We examined 1A binding in several forebrain limbic regions and the dorsal raphe and found no stress- or sex-dependent changes on day 5. We hypothesize that sex differences in 1A binding capacity and mRNA will emerge by day 10 and will correlate with the ability to habituate to stress. These studies provide us with a framework for determining whether the sex difference in neuroendocrine habituation may be explained by differences in the recruitment of 5-HT circuits and function of the 1A receptor. These mechanisms may improve our understanding of the bases for individual and sex-related differences in affective disorders.

Title: Regulation of HPA axis and cardiovascular responses to chronic stress exposure: Role of hindbrain catecholaminergic neurons

Authors: J. BUNDZIKOVA[1,2], S. GHOSAL[1], B. A. PACKARD[1], *J. P. HERMAN[1]
[1]Dept Psychiatry, Univ. Cincinnati, CINCINNATI, OH; [2]Inst. of Exptl. Endocrinol., Bratislava, Slovakia

Abstract: Chronic stress exposure is accompanied by hypothalamic-pituitary-adrenal (HPA) axis hyperactivity and cardiovascular dyshomeostasis. Chronic stress can sensitize the subsequent activation of HPA axis in response to a novel acute stressor. Brainstem norepinephrine (NE) A2 neurons in the nucleus of the solitary tract (NTS) play role in integration of endocrine (HPA axis) and autonomic (cardiovascular system) stress responses. A2 neurons provide the primary NE input to the parvocellular paraventricular nucleus (PVN), which expresses corticotropin-releasing hormone, which is required for ACTH and corticosterone (CORT) secretion. Enhanced NE function contributes to sensitization of HPA axis responses following chronic stress. We hypothesized that A2 cells mediate sensitization to novel stressor following unpredictable stress exposure. To study the role of A2 neurons in the HPA axis and cardiovascular responses to acute restraint stress (RS) and chronic variable stress (CVS), four groups of animals were used. Animals were injected with vehicle or 6-OHDA (10 mg/ml, 2µl). Over half of the animals receiving vehicle or 6-OHDA injection were implanted with radiotelemetry transmitters to afford continuous recording of heart rate, blood pressure and activity. All experimental groups were exposed to acute RS, followed by 14 days of CVS and a novel stressor (NS) (elevated plus maze) on the 15th day. 6-OHDA animals had significantly lower plasma CORT levels 30 min after exposure to acute RS relative to vehicle injected animals. However, we did not find any significant differences in CORT secretion following NS. During RS exposure 6-OHDA animals showed significantly decreased heart rate relative to vehicle injected animals. During CVS (on the 7th day) vehicle animals showed increased low frequency (LF, reflects sympathetic activity) and high frequency (HF, reflects parasympathetic activity) components of heart rate variability and elevated LF/HF ratio (assessed on the 14th day of the CVS). In contrast, no elevations in LF activity were observed in 6-OHDA rats; however, HF activity was diminished (assessed on the 14th day of CVS). After NS exposure, vehicle animals had increased LF/HF ratio and 6-OHDA animals decreased HF. Importantly, while A2 do not appear to be involved in CVS-mediated HPA axis sensitization, they are required for CVS-induced changes in sympathetic drive, and may contribute to deleterious effects of long-term stress on cardiovascular function.

Title: Chronic glucocorticoid intake abolishes the diurnal pattern of slc6a4 and htr1a mRNA expression in anxiety-related serotonergic systems

Authors: *S. MANI, N. C. DONNER, A. J. MATTI, A. J. WACKER, C. A. LOWRY
Integrative Physiol. & Ctr. for Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Research has demonstrated that the diurnal expression pattern of *tph2*, the gene encoding the rate-limiting enzyme during serotonin (5-hydroxytryptamine, 5-HT) synthesis, depends on the circadian glucocorticoid (GC) rhythm. Research from our lab has furthermore established that chronic GC exposure causes an anxiety- and depression-like phenotype associated with an abolished diurnal variation of *tph2* expression due to increased *tph2* expression during the inactive phase (light phase in rodents). We here hypothesized that *slc6a4*, the gene encoding the serotonin transporter (SERT), and *htr1a*, the gene encoding the autoinhibitory 5-HT_{1A} receptor, are also expressed in a diurnal pattern that is altered by chronic GC exposure. To test this hypothesis, we subjected adrenal-intact adult, male rats to 40, 100, or 400 μg/ml corticosterone (CORT) or vehicle (0.45% 2-hydroxypropyl-β-cyclodextrin) via the drinking water for 21 days, and assessed *slc6a4* and *htr1a* mRNA expression within the serotonergic dorsal raphe nucleus (DR), the main source of brain 5-HT, using *in situ* hybridization histochemistry. We found that CORT-treatment specifically affected *slc6a4* and *htr1a* mRNA expression within specific DR subregions. In vehicle-treated rats, the anxiety-related dorsal DR (DRD) displayed a diurnal variation in *slc6a4* expression that was abolished in CORT-treated rats by suppressing *slc6a4* expression dose-dependently during the rats' active dark phase. CORT treatment also decreased dark-phase *slc6a4* expression in the caudal part of the ventral DR (cDRV), an area that provides a dense innervation of the sensorimotor cortex, among other brain regions, and is consistently affected in chronic anxiety models that involve vulnerability to panic-like responses. Expression of *htr1a* occurred in a diurnal pattern within the anxiety-related caudal DR (DRC), a pattern that was, again, abolished by chronic CORT treatment. No other subdivisions displayed a diurnal expression pattern of either gene, suggesting an indirect effect of chronic CORT treatment on gene expression, possibly via alteration of afferent signaling from the extended amygdala complex. The observed changes in *tph2, slc6a4*

and *htr1a* expression may result in an overactive serotonergic system (more 5-HT production, less 5-HT reuptake, and disrupted diurnal 5-HT_{1A}-mediated autoinhibition) particularly within those DR subdivisions previously associated with control of anxiety-related behavior. The effects of CORT-induced changes in *slc6a4* and *htr1a* expression on serotonergic activity in forebrain structures remains to be determined.

Title: Stress, adrenergic function and post-traumatic stress disorder

Authors: *D. WONG[1], K. M. MYERS[2], R. CLAYCOMB[1], W. A. CARLEZON, Jr.[2]
[1]Psychiatry/Laboratory of Mol. and Developmental Neurobio., [2]Psychiatry/Behavioral Genet. Lab., Harvard Med. School/McLean Hosp., BELMONT, MA

Abstract: Stress and epinephrine (EPI) contribute to both physiological and behavioral illnesses. As a stress hormone, epinephrine (EPI) plays a pivotal role in enabling organisms to restore homeostasis and overcome stress. We have shown that EPI itself is stress-regulated through its biosynthesis by phenylethanolamine N-methyltransferase (PNMT). In the adrenal of rats subjected to single or repeated immobilization (IMMO) or rat adrenal medulla-derived PC12 cells exposed to moderate hypoxic stress (5% oxygen), marked elevation of PNMT mRNA and protein is induced, preceded by a rise in the PNMT gene transcriptional activators, Egr-1, Sp1 and HIF1alpha mRNA and protein. However, little is known about mechanisms by which EPI contributes to illness. Post-traumatic stress disorder (PTSD) is a behavioral illness that continues to escalate, particularly in war veterans returning from Iraq and Afghanistan, children and teenagers. PTSD patients show memory extinction deficits and elevated EPI, with relief of symptoms provided by adrenergic antagonists. We have recently developed a rat PTSD model

using immobilization (IMMO) stress and have demonstrated that stress-induced elevation of PNMT and EPI alters adrenergic drive through central learning and memory circuitry. Long-term adaptive/maladaptive changes are apparent, with maladaptive changes having the potential to evoke illness. Rats trained in fear extinction exhibit deficits in extinction memory consolidation and/or retrieval in the rat fear-potentiated startle (FPS) paradigm when subjected to 2 hr sessions of daily IMMO for at least one week. Adrenal adrenergic indices are concomitantly elevated, including Egr-1, HIF1alpha and PNMT mRNA and protein. In contrast, behavior deficits and changes in adrenergic indices do not occur in rats trained in fear extinction and exposed to a single IMMO. Present studies are examining how IMMO duration and adrenergic antagonists affect these observed behavioral and adrenergic changes in this rat PTSD model.

Title: Chronic glucocorticoid intake increases basal- and stress-induced tryptophan hydroxylase activity in anxiety-, sleep/wake-, and memory-related serotonergic systems

Authors: *N. C. DONNER, P. H. SIEBLER, S. MANI, C. A. LOWRY
Integrative Physiol. & Ctr. for Neurosci., Univ. of Colorado Boulder, Boulder, CO

Abstract: Major depressive disorder is linked to both disruption of hypothalamic-pituitary-adrenal (HPA) axis function and dysfunction of brain serotonin (5-hydroxytryptamine, 5-HT) systems. However, causal relationships leading to dysregulation of these systems are still unclear. To test the hypothesis that chronic glucocorticoid (GC) exposure, without external stressors *per se*, alters both basal and stress-induced activity of tryptophan hydroxylase (TPH), the rate-limiting enzyme for 5-HT synthesis, we treated adrenal-intact adult, male rats with 100 μg/ml corticosterone (CORT) or vehicle (0.45% 2-hydroxypropyl-β-cyclodextrin) via the drinking water for 21 days. We monitored weight gain and diurnal food and water consumption, and assessed the rats' emotionality in the elevated plus-maze (EPM) and forced swim tests (FST)

after two weeks. On day 21, all rats were injected with 100 mg/kg NSD-1015, an inhibitor of aromatic amino acid decarboxylase, to block the conversion of 5-hydroxytryptophan (5-HTP) to 5-HT. Following the injection, rats were either exposed to acoustic startle (AS) for 30 min or remained in home cages until rapid decapitation. *Post mortem,* we assessed *ex vivo* adrenal functionality in a tissue culture assay, and measured 5-HTP accumulation, a readout of TPH activity, in the median raphe nucleus (MnR) and dorsal raphe nucleus (DR) subregions, and in anxiety-related forebrain target areas, using high-pressure-liquid chromatography. Chronic CORT intake caused reduced weight gain, anxiety-like behavior on the EPM, increased immobility in the FST, an increased AS response, and adrenal insufficiency. The diurnal pattern and the amount of food and water intake remained unchanged. Most importantly, chronic CORT elevated both basal and AS-induced TPH activity in the dorsal (DRD) and ventral DR (DRV), as well as basal TPH activity in the MnR. In the caudal DR (DRC), the infralimbic cortex (IL), the dorsal *cornu ammonis* region of the hippocampus (dCA1) and the caudal pontine reticular formation (PnC), AS elevated TPH activity only in CORT-, but not in vehicle-treated rats, indicating a permissive effect of chronic CORT. The increase of TPH activity in the PnC was strongly correlated with the magnitude of the AS response. Our results are novel, and suggest that GCs exert their chronic actions by creating either a basal hyperactivity or a hypersensitivity to an acute stressor in those serotonergic circuitries that modulate anxiety-related behavior (DRC, DRD, DRV, IL) as well as sleep/wake function (MnR, PnC) and learning and memory (dCA1).

Title: The effect of short-term stress on serotonin gene expression in high and low resilient macaques

Authors: C. L. BETHEA[1,2,3,4], K. PHU[1], A. P. REDDY[1], *H. M. RIVERA[1], J. L. CAMERON[5]
[1]Oregon Natl. Primate Res. Center/ Div. of Reproductive Sci., Beaverton, OR; [2]Div. of Neurosci., Oregon Natl. Primate Res. Ctr., Beaverton, OR; [3]Dept. of Behavioral Neurosci., [4]Dept. of Obstetrics and Gynecology, Oregon Hlth. and Sci. Univ., Portland, OR; [5]Dept. of Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Female cynomolgus monkeys exhibit different degrees of reproductive dysfunction with moderate metabolic and psychosocial stress. When stressed with a paradigm of relocation and diet for 60 days, or 2 menstrual cycles, highly stress resilient monkeys continue to ovulate during both stress cycles (HSR); medium stress resilient monkeys ovulate once (MSR) and stress sensitive monkeys do not ovulate for 60 days or more (SS). This study examines serotonin-related gene expression in monkeys with different sensitivity to stress and exposed to 5 days of moderate stress. Monkeys were first characterized as HSR, MSR or SS. After resumption of menstrual cycles, each monkey was re-stressed for 5 days in the early follicular phase. The expression of 3 genes pivotal to serotonin neural function was assessed in the 3 groups of monkeys (n=4-5/group). Tryptophan hydroxylase 2 (TPH2), the serotonin reuptake transporter (SERT), and the 5HT1A autoreceptor were determined at 7 morphological levels of the dorsal raphe nucleus with in situ hybridization (ISH) using digoxygenin-incorporated riboprobes. Positive pixel area and cell number were measured with ImageJ. All data were analyzed with ANOVA. After 5 days of stress, there was no significant difference in TPH2, SERT or 5HT1A gene expression between groups. This pattern of expression differed markedly from the pattern observed in the absence of stress in previous studies. Therefore, the pattern of expression was examined in HSR and SS groups in the absence and presence of stress. In the absence of stress, TPH2, SERT and 5HT1A gene expression was 54%, 128% and 36% higher in the HSR group than the SS group, respectively. In the presence of stress, TPH2 and SERT expression were less than or equal in the HSR and SS groups. However, 5HT1A remained 36% higher in the HSR group than the SS group. In addition, the ratio of HSR/SS gene expression for TPH2, SERT and 5HT1A equaled, respectively, 1.54, 2.28, and 1.36 in the absence of stress and 0.72, 0.98 and 1.36 in the presence of stress. We speculate that the SS group had an ‘acute stress response’ with an immediate increase in TPH2 and serotonin production, which correlates with an increase in SERT expression, while the HSR group may not have responded profoundly. However, 5HT1A expression may have been slower to change, which is also observed after antidepressant treatment. In summary, SS animals perceived stress and serotonin neurons responded quickly to 5 days of moderate metabolic and psychosocial stress. How the serotonin system functions after a longer period of stress that is sufficient to suppress ovulation is the subject of ongoing experiments.

Title: Neuropeptide y reverses chronic stress-induced baroreflex hypersensitivity in rats

Authors: *J. AI, F. XIE, L. SUN, X. SU, Y. WANG, J. LIU, R. ZHANG, N. WANG, T. BAN
Dept. of Pharmacol., Harbin Med. Univ., Heilongjiang, China

Abstract: Chronic stress, as a risk factor for cardiovascular diseases, has been reported to result in elevated plasma neuropeptide Y (NPY) and be highly associated with abnormal cardiac autonomic function. This study aimed to explore the effect of NPY on the chronic stress-induced abnormal baroreceptor reflex sensitivity (BRS). Seven types of recognized stressors were used to develop chronic stress rat model. Subcutaneously implanting ALZET mini-osmotic pumps containing NPY were used to evaluate the action of NPY on the stressed male rats. We found that chronic stress showed no influence on baseline systolic blood pressure (SBP) and heart rate (HR), whereas NPY (85 μg for 30 days) could elevate baseline SBP and induce bradycardia in rats intervened by various stimuli. NPY pretreatment could preserve chronic stress-induced decreases in left ventricular systolic pressure (LVSP) and the maximum rate of change in left ventricular pressure in the isovolumic contraction period ($+dp/dt_{max}$) but has shown no effect on left ventricular end diastolic pressure (LVEDP) and the maximum rate of change in left ventricular pressure in the isovolumic relaxation period ($-dp/dt_{max}$). Notably, chronic stress led to baroreflex oversensitivity indicated by the elevated ratio of ΔHR/Δmean arterial blood pressure (MABP) in rats followed by vasoconstrictor (phenylephrine, PE) or vasodilator (sodium nitroprusside, SNP) administration, which was almost completely reversed by NPY pretreatment. The expressions of substance P (SP) and gamma aminobutyric acid A receptor ($GABA_AR$) in nucleus tractus solitarius were increased in chronic stress rats, which were counteracted by NPY pretreatment. We conclude that chronic stress-induced baroreflex hypersensitivity could be blocked by NPY pretreatment. Furthermore, the altered expressions of neurotransmitters and receptors in the brainstem might contribute to this process. Conflict of interest: The authors declare no competing financial interest. Title: Targeting of the dorsal raphe nucleus by amygdalar afferents

Authors: *E. J. VAN BOCKSTAELE[1], T. A. RETSON[1], R. J. VALENTINO[2]
[1]Neurosci., Thomas Jefferson Univ., PHILADELPHIA, PA; [2]Dept. of Anesthesiol. and Critical Care Med., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: According to the National Institute of Mental Health, nearly 10% of the American adult population is affected by a mood disorder in a given year, with the costs of mental healthcare reaching billions of dollars. One of the major forms of treatment in the management of affective disorders is administration of selective serotonin reuptake inhibitors. The dorsal raphe nucleus (DRN) is enriched in serotonergic neurons that provide the primary source of serotonin to the forebrain and is a region profoundly impacted by stress. To better understand the regulation of the DRN by the amygdalar stress-related peptides, corticotropin releasing factor (CRF) and dynorphin (DYN), we examined projections from the central nucleus of the amygdala (CeA) to the DRN-5HT system using retrograde tract-tracing from the DRN, and immunocytochemical identification of CRF and DYN in the CeA. Fluorescent latex microspheres (Retrobeads, Lumafluor) were injected into the DRN of adult male rats and were directed at its ventromedial quadrant at the anterior-posterior coordinate of Bregma -7.7mm (Paxinos and Watson, 1986). Rats were perfused one week after injection, and brains were sectioned for analysis. Retrogradely labeled neurons were identified within the CeA confirming previous studies. Specifically, when injections were placed in the ventromedial division of the DRN (n=3), analysis revealed that 595±32 neurons were present in the rostral aspect of the CeA, 843±87 were present in the mid-region of the CeA and 252±32 in the caudal region of the nucleus. Approximately 28% of DRN-projecting neurons in the CeA exhibited CRF, while 35% contained DYN. Considering the importance of the amygdala in stress sensitivity and associating salience with emotional cues in the environment, understanding the influences of this limbic

region on the DRN may help fill a gap in our knowledge regarding neural circuits impacting 5HT systems, and may offer additional insight into treatment targets for affective disorders.

Title: Restraint stress affects Galectin-1 level in serum and organs of adult rats

Authors: *T. KADOYA[1], M. IWAMOTO[2], S. KOIZUMI[2], H. HORIE[2], E. KOSHINO[1], T. YAMAMOTO[3], K. SASAGURI[2]
[1]Dept. of Biotech., Maebashi Inst. of Technol., Maebashi, Gunma, Japan; [2]Dept. of Craniofacial Growth and Develop. Dent., [3]Dept. of Human Biol., Kanagawa Dent. Col., Yokosuka, Japan

Abstract:
Stress is inherent in modern society, and it has the potential to disturb the normal functions of many systems of the human body, including the nervous system, the endocrine system, and the immune system. Therefore, the investigation of the markers that show stress at an early stage will be useful and important for diagnostic and therapeutic purposes.
Galectin-1 (Gal-1), an animal lectin with an affinity for β-galactoside, is widely expressed in various normal and pathological tissues and shows a variety of biological activities, such as immune-cell homeostasis, tumorigenesis, nerve regeneration after injury, and the inflammatory response. However, the effect of various types of stress on the Gal-1 level is unclear. In this study, we employed a restraint stress model using male adult rats and investigated the effect on Gal-1 level in serum and several organs by western blot analysis and ELISA. The *in vivo* experiments demonstrated that Gal-1 quickly responds to the stress, the restraint stress markedly increases the serum Gal-1 level. The Gal-1 increase in the serum was inhibited by pre-treatment with a neurotoxin 6- hydroxydopamine, which destroys the noradrenergic nerve terminals. On the other hand, a bilateral adrenalectomy had no effect on the Gal-1 increase. These results suggest that the stress-induced increase of Gal-1 in serum is regulated by the sympathetic nervous system under stress conditions. Furthermore, the Gal-1 levels increased in thymus and spleen at 30min and 60 min after the restraint stress. Gal-1 may therefore play an important role in the reaction to the stress and be a good novel candidate as a stress marker.

Title: Endocannabinoid signaling as an intrinsic component of the circuits mediating adaptive responses to repeated stress exposures

Authors: *R. J. NEWSOM, C. V. MASINI, T. J. NYHUIS, H. E. DAY, S. CAMPEAU
Psychology, Univ. of Colorado Boulder, BOULDER, CO

Abstract: Evidence implicates the endocannabinoid (eCB) system as a negative modulator of neural and endocrine responses to acute stressors. Recently, eCBs were also shown to influence the development of habituated hypothalamo-pituitary-adrenal (HPA) axis responses to repeated homotypic stress, in which repeated exposures to the same stressor reliably decreases subsequent activation of the HPA axis. The present studies were initiated to distinguish a potential role of eCB signaling in the acquisition as compared to the expression of habituated HPA axis responses. Adult male Sprague Dawley rats (Harlan) were exposed to daily, 30 minute sessions of loud white noise (95 dB) for 8 days. Rats received either the cannabinoid receptor 1 (CB1) antagonist AM251 (2mg/kg or 0.5mg/kg, i.p.) or vehicle 30-min before the loud noise sessions on the first 7 days, but not on the 8th day of stress exposure. Blood samples were taken after loud noise on days 1, 4, 7, and 8. The rats treated with 2 mg/kg AM251 had higher levels of plasma corticosterone (CORT) on days 1,4, and 7, and a slower rate of habituation than rats receiving vehicle or 0.5 mg/kg injections of AM251. However, on day 8 of noise (drug-free), 2 mg/kg AM251-treated rats had near complete attenuation of HPA axis response, as observed in rats receiving vehicle or 0.5 mg/kg AM251 injections during the initial 7 loud noise exposures. This suggests that disruption of CB1 receptor signaling does not disrupt the plasticity associated with acquisition of habituation to repeated homotypic stress. In a second study, rats were exposed to daily loud noise stress for 7 days to establish HPA axis habituation without drug treatments. Twenty-four hrs later, rats were injected with 1 mg/kg AM251 or vehicle, 30 min prior to a final 30-min loud noise exposure. Vehicle-treated rats displayed reliable habituation of HPA axis response, but CB1 antagonism disrupted the expression of this habituated response, by restoring

plasma CORT to levels observed during the initial (day 1) loud noise exposure. Rats were given an additional mild stress exposure (novel environment) 24-hours later, along with a cohort of rats not previously habituated to noise stress. 1 mg/kg AM251 treatment prior to novel environment resulted in a significantly larger HPA axis response, but only in rats recently habituated to repeated loud noises. These results point to eCB signaling as an intrinsic component of the circuits expressing adaptive responses to repeated stress, without itself mediating the plasticity associated with repeated stress exposures.

Title: Gender differences in serotonergic stress response in stalk-eyed flies(Teleopsis dalmanni)

Authors: *N. S. RIEGER, A. N. BUBAK, J. E. HASSELL, Jr, H. LI, K. J. RENNER, J. G. SWALLOW
Biol., Univ. of South Dakota, Vermillion, SD

Abstract: The impact of acute stress on brain function, including perturbations of the monoaminergic systems, have important implications for behavioral coping responses. Stress responses often vary among individuals and between genders in phylogenetically diverse organisms. In the stalk-eyed fly (*Teleopsis dalmanni*), a sexually dimorphic species, we initially tested if brain 5-HT concentrations differed between males and females. In a second experiment, we tested the effects of restraint and a combination of restraint and heat stress on brain 5-HT in both sexes. Restraint was accomplished by placing the flies in a 1.5 mL tube for 30 min. Heat stress was induced by emerging the tubes in a water bath set at 36 ^{o}C for 30 min. Brain 5-HT from each individual fly was measured using HPLC with electrochemical detection. We found that 5-HT levels did not differ between control, non-stressed, male and female flies (mean $\pm$ SEM: 7.22±1.73, 7.65±1.56 respectively). In addition, exposure to restraint did not significantly affect 5-HT levels for flies of either sex when compared to untreated controls. However, whole

brain 5-HT levels in males increased 89.6% in response to the combined heat and restraint stress ($P < .027$). In contrast, females exhibited a trend for a decrease in 5-HT in response to the combined stress ($P<0.053$). Additionally, stress-induced changes in 5-HT levels differed when males were compared to females ($p<.003$). These results suggest that the central control of stress responsiveness is sexually dimorphic in the stalk-eyed fly. Supported by NSF grants IOS 0921874 (KJR) and IOB 0448060 (JGS).

Title: Maternal obesity and IL-6 lead to aberrant developmental gene expression and deregulated axon growth in the fetal arcuate nucleus

Authors: *C. JASONI[1], T. R. SANDERS[2]
[1]Ctr. for Neuroendocrinology and Dept. of Anat., [2]Dept Anat., Univ. of Otago, Dunedin, New Zealand

Abstract: Maternal obesity during pregnancy is a well-accepted predetermining factor for offspring risk of obesity. Several observations have pointed to a causative role for the pro-inflammatory cytokine interleukin 6 (IL-6), but how and where it acts on the developing fetus is unclear. We reasoned that elevated IL-6 might alter the formation of neural connections made by body weight control neurons in the fetal arcuate nucleus of the hypothalamus (ARC), the primary site for neural control of body weight. Such an effect may thereby program offspring for deregulated body weight control later in life.
In initial experiments, explants of fetal ARC treated with IL-6 in vitro showed a significantly reduced ability to extend neurites, indicating that IL6 exposure may have a detrimental effect on the ability of the fetal ARC to make neural connections. To assess whether the expression of genes involved with neurite growth regulation may be modulated by IL-6, the expression of

several genes was quantitated in ARC tissue treated with IL-6 in vitro. The expression of Deleted in Colorectal Cancer (DCC), a receptor for the axon growth and guidance molecule Netrin-1, and Gli1, a signaling molecule in the canonical Sonic hedgehog pathway, were found to be significantly increased by IL-6 treatment of ARC tissue in vitro. Strikingly, both genes were also found to be increased in the ARC of fetuses developing in obese, but not normal weight, mothers.
Together, these data suggest that one mechanism by which maternal body weight may program offspring for elevated body weight is through an IL-6-dependent disruption of gene expression that regulates the normal formation of body weight control circuits in the fetal ARC.

Title: Reduction of insulin secretion and desensitization to insulin-brain effects may contribute to hypophagia induced by prolonged LPS treatment.

Authors: *R. C. RORATO, B. C. BORGES, E. T. UCHÔA, P. B. MARANGON, J. ANTUNES-RODRIGUES, L. L. K. ELIAS
Physiol., Sch. of Med. of Ribeirao Preto - Univ. of São Paulo, Ribeirão Preto, Brazil

Abstract: It is well-known that insulin and leptin induce hypophagia after intracerebroventricular (icv) injection. The plasma levels of both hormones are increased after acute lipopolysaccharide (LPS) administration. On the other hand, prolonged LPS injection induces desensitization of leptin secretion and leptin-induced hypophagia. In the present study we aimed to investigate if prolonged LPS treatment also desensitizes insulin secretion and their central hypophagic effects. For this purpose rats were assigned to three different groups of LPS i.p. treatment at 16:00: saline once daily for 6 days (saline), saline once daily for 5 days and an injection of LPS at the 6th day (1LPS) and LPS once daily for 6 days (6LPS). On the day of the

experiment, food were removed after treatments and two (18:00) and four (20:00) hours after, the rats were decapitated for plasma collection. We also collected the brain of rats decapitated 2 hours after injections for western blot analyses of mediobasal hypothalamus. A second set of rats were previously icv cannulated and on the day of the experiment, at 15:30, they received insulin (12uM/5uL) or vehicle (saline) and their food consumptions and body weight were determined 2 and 14 hours after, respectively. We observed in 1LPS group, but not 6LPS group, an increased plasma insulin levels 4h after treatments. In addition, 1LPS, but not repeated LPS rats, showed higher expression of IRS-1 in the mediobasal hypothalamus. As expected, we observed in vehicle-treated group a decrease of food intake and body weight in 1LPS-treated rats and no changes in rats that received 6 doses of endotoxin. On the other hand, insulin reduced food intake and body weight gain in saline treated group, but there were no changes in food intake and body weight in 1LPS or 6LPS group. The present data suggest that desensitization of hypophagia after long term LPS treatment may be related to reduction of insulin secretion and decreased insulin signaling. IRS-1 could play a role in the development of desensitization of LPS responses and insulin hyporesponsiveness under prolonged endotoxin exposure.

Title: Astrocytes as glucosensors in the solitary nucleus

Authors: D. H. MCDOUGAL, *R. C. ROGERS, G. E. HERMANN
Pennington Biomed. Res. Ctr., Baton Rouge, LA

Abstract: The regulation of serum glucose is critical for brain function. The autonomic response to hypoglycemia is characterized by a collection of responses referred to as counter-regulation (CR) which ultimately raises glucose to euglycemic levels. Brainstem astrocytes may be

important chemodetectors for autonomic control contributing to the initiation of the CR. These experiments were conducted to see if brainstem astrocytes actively signal during conditions of low glucose availability. Further, we examined whether one manifestation of CR, hypoglycemia-induced “cephalic phase” increases in gastric motility, were sensitive to inactivation of brainstem astrocytes. In vitro, confocal live cell imaging of acute brainstem slices from adult Long Evans rats was used to quantify cellular activation of astrocytes and neurons in the nucleus of the solitary tract (NST) during low glucose or glucoprivic [2DG] challenges. Changes in intracellular calcium levels reflected the activation of pre-labeled astrocytes and neurons. Slices were exposed to 10min interval of low glucose or glucoprivic challenge [0.5mM glucose, 1.0mM glucose or 5mM 2-deoxyglucose (2-DG)]. These conditions reversibly evoked significant increases in intracellular calcium in both NST astrocytes and neurons. Activated astrocytes had significantly larger responses and shorter latencies to respond relative to the NST neurons. Additionally, the astrocytic activation induced by low extracellular glucose was maintained even in the presence of 1μM TTX, eliminating the possibility of a neuronal origin of the astrocytic response. A separate experiment suggests that astrocyte detection of glucoprivation is essential to at least one aspect of CR. 2DG applied to the floor of the fourth ventricle [17umole] elicits a significant increase in gastric motility. Fluorocitrate, [astrocyte metabolic inhibitor; 5nM] applied to the fourth ventricle has no effect on basal gastric motility but blocks the 2DG driven increase in gastric motility. These data suggest that NST astrocytes are intrinsically glucosensitive and are capable of actively signaling in response to low glucose availability. This active signaling may play a pivotal role in driving autonomic mechanisms associated with CR.

Title: Role of astrocytes and ketone bodies in neuronal fatty acid sensing and feeding.

Authors: *A. A. DUNN-MEYNELL[1], B. E. LEVIN[1,2], C. LE FOLL[2]
[1]VA Med. Ctr., East Orange, NJ; [2]NJ Med. School/UMDNJ, Newark, NJ

Abstract: Select metabolic sensing neurons in the brain alter their activity when ambient levels of metabolic substrates such as glucose and fatty acids (FA) change. Select neurons that “sense” long chain fatty acids reside in the ventromedial hypothalamus (VMH). Astrocytes are potential mediators of the responsiveness of these neurons since astrocytes are the major source of long chain fatty acid oxidation and the only known source of ketone body production in the brain. To assess the role of ketone bodies in VMH neuronal FA sensing, fura-2 calcium imaging was used as a surrogate marker for neuronal activity in dissociated VMH neurons from 3-4 wk old rats. Glucose levels were changed from 2.5 to 0.5 to 2.5 mM glucose to identify glucosensing neurons and then 15nM oleic acid (OA) was added to identify FA sensing neurons. When then exposed to β-hydroxybutyrate (βOHB; 10nM to 100μM), neuronal responses were dependent upon the glucose concentration; the overall proportion of βOHB excited neurons was 66% higher in 2.5mM (48%) than in 0.5mM glucose (29%). In addition, 40% of the OA-excited neurons were further excited by βOHB, while 50-70% of OA inhibited neurons were excited by increasing concentrations of βOHB. To assess the potential role of astrocyte-derived ketone body production on feeding, VMH microdialysis for βOHB was performed on male Sprague-Dawley rats after they were trained over a 3 wk period to eat all their daily calories in a 3h period as 4.5% fat chow (n=10) or 60% fat (HFD; n=10)). On the day of testing, after their initial 3h diet feeding periods, they were then allowed to eat 4.5% chow ad libitum to assess the satiating effect of their respective diet preloads. Jugular venous blood and VMH microdialysis samples were taken every 30 min over an 8h period and food intake was monitored for 24h in a BioDAQ Food Intake Monitor (Research Diets). Rats in both diet groups ate comparable calories during the 3h preload but subsequent chow was 40% and 22% lower over the next 3h ($P<0.05$) and total 24h test period in rats previously preloaded with HFD vs. chow ($P<0.05$) . During the first 1h of the 3h preload, the VMH/ blood ketone ratio increased by 400% during HFD with a variable rise or return of the ratio to pre-feeding levels over the next 8h. Chow feeding caused no increase in VMH/blood ketones. These results suggest that ketone bodies have a primarily excitatory effect on VMH FA sensing neurons, even in the presence of FA, and that astrocytes utilize excess dietary FA to produce these ketones. Thus, HFD-induced increase in VMH ketone levels may alter neuronal FA sensing and play a role in the reduced food intake that follows a HFD preload.

Title: Role of FAT/CD36 in neuronal fatty acid sensing and energy homeostasis regulation

Authors: C. LE FOLL[1,2], A. A. DUNN-MEYNELL[1], S. MOUSATOV[3], C. MAGNAN[4], *B. E. LEVIN[1,2]
[1]VA Med. Ctr., EAST ORANGE, NJ; [2]Neurol. and Neurosciences, NJ Med. School/UMDNJ, Newark, NJ; [3]Weill Cornell Med. Col., New York, NY; [4]BFA CNRS-University Paris Diderot, Paris, France

Abstract: The hypothalamus contains "metabolic sensing neurons" which play an integral role in the regulation of glucose and energy homeostasis and the development of obesity and diabetes. Many of these neurons utilize both glucose and long chain fatty acids (LCFA) to alter their activity as a means of monitoring the metabolic status of the body. Using pharmacologic agents, we previously found that 50% of these neurons responded to the LCFA, oleic acid (OA), by utilizing the fatty acid (FA) translocator/receptor, FAT/CD36. To further elucidate the role of CD36 in neuronal FA sensing, adeno-associated viral (AAV) vectors expressing CD36 or luciferase shRNAs as well as mCherry fluorescent marker were injected into the ventromedial hypothalamus (VMH) of P5 Sprague-Dawley rats. At P21-P25, dissociated VMH neurons were obtained from these rats and subjected to fura-2 calcium imaging as a surrogate marker for changes in neuronal activity. Glucose levels were first changed from 2.5 to 0.5 to 2.5 mM to identify glucosensing neurons. They were then exposed to 15 nM OA to identify FA sensing neurons. Neuronal glucosensing was not affected by the CD36 AAV shRNA injections. However, whereas 16% of control (Ctrl) glucose inhibited neurons were also inhibited by OA, none were inhibited in CD36 AAV shRNA rats ($P<0.05$ vs. Ctrl). Also, whereas 47% of Ctrl glucose excited neurons were also excited by OA, only 25% of CD36 AAV shRNA neurons were excited by OA ($P<0.05$ vs. Ctrl). Next, to assess the role of CD36-mediated neuronal FA sensing in the regulation of energy homeostasis, CD36 AAV shRNA or Ctrl AAV were injected into the VMH of P21 male Sprague-Dawley rats. Rats were fed 4.5% fat chow (Ch) for 6 wk, followed by 9 wk on 45% high fat diet (HFD). After 6 wk on chow, the CD36 AAV shRNA rats ate less than Ctrl rats at 1h (-36%, $P<0.05$), 5h (-34%, $P<0.05$) and 24h (-22%, $P<0.05$) when refed after a 24 h fast. Chow-fed CD36 AAV shRNA rats also had elevated fasting plasma glucose (+11%), insulin (+72%) and leptin (+171%) levels vs. Ctrl rats ($P<0.05$). After 9 wk on HFD, CD36 AAV shRNA rats showed no difference in food intake or body weight gain but displayed heavier inguinal fat pad weights (+68%, $P<0.05$) and had higher leptin levels (+54%, $P<0.05$) as compared to Ctrl rats. They also had a markedly abnormal oral glucose tolerance test with 98% higher glucose ($P<0.05$) and 244% higher insulin ($P<0.05$) areas-under-the-curve levels vs. Ctrl rats. These alterations were associated with a 69% decrease of CD36 mRNA expression in the arcuate nucleus of CD36 AAV shRNA rats ($P<0.05$). These results demonstrate

that CD36 is a critical factor in both VMH neuronal FA sensing and the regulation of energy and glucose homeostasis.

Title: Involvement of the astroglial networks in the hypothalamic glucose-sensing: Role of Connexin 43

Authors: *C. ALLARD[1], L. CARNEIRO[1], S. GRALL[1], B. CLINE[1], X. FIORAMONTI[1], C. CHRETIEN[1], F. BABA-AISSA[1], C. GIAUME[2], L. PENICAUD[1], C. LELOUP[1]

Abstract: Introduction
The hypothalamus plays a pivotal role in regulating glucose homeostasis. Hypothalamic detection of increased blood glucose levels, by specific hypothalamic glucose sensitive neurons, triggers physiological responses such as increased insulin secretion and decreased hepatic glucose production. Astrocytes are emerging as important candidates involved in brain glucose-sensing. They create an intricate organized network formed by numerous gap-junctions (GJ) comprised of connexins, allowing for the transfer of glucose from the bloodstream to neurons. The main connexin expressed in astrocytes is connexin 43 (Cx43). We hypothesize that the Cx43-dependant astroglial networks play a critical role in hypothalamic glucose-sensing.
Materials and Methods
Expression of Cx43 was first characterized by immunochemistry in the rat ventro-median hypothalamus (VMH) and then studied using different metabolic conditions (hyperglycemia or fasting). VMH Cx43 was inhibited, in vivo, by stereotaxic injection of siRNA against Cx43 in rats. Hypothalamic glucose-sensing was evaluated by monitoring pancreatic insulin secretion in

response to an intracarotid injection of a glucose bolus towards the brain.
Results
Cx43 was highly expressed in the VMH at astrocytic end-feet enwraping blood vessels. Cx43 expression increased after 3h-hyperglycemia and decreased after fasting. Inhibition of Cx43 (about 30%) led to a decrease of food intake, 72h after the injection, without modifying weigth, blood glucose and insulin levels. Intracarotid glucose injection-induced insulin secretion was significantly decreased in siCx43 rats.
Conclusion
These results show that Cx43 presents a specific expression pattern in the hypothalamus. Moreover, this Cx43 expression varies upon the metabolic status. The central response to glucose (insulin secretion) was lost by inhibition of hypothalamic Cx43. We conclude that Cx43-dependant astroglial networks are critical for hypothalamic glucose sensitivity.

Title: The effect of obesity on microglial activation, inflammation and the renin-angiotensin system in specific brain nuclei

Authors: *A. D. DE KLOET[1], J. A. SMITH[2], D. NGUYEN[2], E. G. KRAUSE[2], C. SUMNERS[1]
[1]Physiol. and Functional Genomics, Univ. of Florida, Col. of Med., Gainesville, FL;
[2]Pharmacodynamics, Univ. of Florida, Col. of Pharm., Gainesville, FL

Abstract: Although energy balance is tightly regulated, the incidence of obesity continues to rise. Obesity is associated with increased prevalence of hypertension and cardiovascular disease. As a consequence, it is imperative that effective treatment strategies for obesity and its co-morbidities are uncovered and this can only be achieved by attaining a thorough understanding of the factors that regulate the homeostatic systems involved. Among these factors are proinflammatory cytokines and the components of the renin-angiotensin system (RAS), which are elevated during both obesity and hypertension.

Here, we hypothesize that an important mechanistic link between high-fat diet (HFD)-induced metabolic and cardiovascular dysregulation is an increase in RAS activity and inflammation within brain regions regulating energy balance and blood pressure. Consistent with this, previous studies indicate that consumption of HFD enhances microglial activation within the arcuate nucleus (ARC; a metabolic control center). Moreover, we have found that leptin, an endocrine factor that becomes elevated during obesity, increases the synthesis of proinflammatory cytokines (tumor necrosis factor-α, interleukin-1β, interleukin-6) in hypothalamic microglial cultures. Nonetheless, the effect of HFD feeding and other obesity-related factors on microglial activation, inflammation and RAS activity in cardiovascular and other metabolic control centers is largely unknown.
In the present studies, adult male C57BL/6 mice were given either a HFD or a low-fat diet (LFD) for 3 days or 8 weeks and the effect of HFD-feeding on microglial activation, inflammation and the RAS within metabolic and cardiovascular control centers was examined via immunohistochemistry and RT-PCR. Eight weeks of HFD feeding resulted in increased body mass and adipose mass. Consumption of HFD led to an increase in the number and activation (based on morphological changes) of microglia within the ARC, the subfornical organ (SFO), and the parvocellular region of the paraventricular nucleus of the hypothalamus (PVN), but not within the magnocellular region of the PVN. Collectively, these data are consistent with the hypothesis that HFD feeding initiates an inflammatory cascade within specific brain regions that may then contribute to disturbed energy and cardiovascular homeostasis.

Title: Generation of transgenic mice with vimentin-driven reporter fluorescence in the ependymocytes

Authors: *S. MINABE[1], C. DEURA[1], T. GOTO[1,2], M. SANBO[2], K. TOMITA[2], M. HIRABAYASHI[2], Y. UENOYAMA[1], K.-I. MAEDA[1], H. TSUKAMURA[1]
[1]Nagoya Univ., Nagoya, Japan; [2]Ctr. for Genet. Analysis of Behavior, Natl. Inst. for Physiological Sci., Okazaki, Japan

Abstract: Ependymocytes, lining the ventricular surface of the central nervous system, have widely been known to play functional roles, such as energy supports for neighboring neurons. Our previous studies showed that the ependymocytes in the fourth ventricle (4V) or central canal (CC) express key molecules for glucose sensing, such as glucokinase and glucose transporter 2. Thus, we proposed that ependymocytes in the lower brainstem were equipped with a glucose-sensing mechanism, thereby controlling feeding behavior and reproductive functions. To study the intracellular mechanism by which ependymocytes sense the levels of glucose or other energetic molecules, we generated a new transgenic mouse model to visualize ependymocytes with fluorescence proteins. Vimentin, a marker of ependymocytes, was chosen to drive the ependymocytes-specific gene expression. Two types of mouse vimentin promoters (*pVim*) were chosen: full-length *pVim* (3.2 kb) and short *pVim* (0.2 kb). Five transgenic founder mice were generated by microinjection of each DNA construct into mouse oocytes. The transgenic mice with full-length *pVim* successfully expressed reporter fluorescence in ependymocytes of the lateral ventricle, third ventricle, 4V and CC. On the other hands, the short *pVim*, which was reported as essential region for basic promoter function *in vitro*, did not drive reporter fluorescence expression in any ependymocytes. These results indicate that upstream region (3.0 kb) of short *pVim* is essential for the ependymocytes-specific gene expression *in vivo*. The current transgenic mice will be useful for the analysis on functions of ependymocytes, such as intracellular energy-sensing mechanism.

Title: Distinct routes for interleukin-1 and lipopolysaccharide-induced anorexia

Authors: *A. NILSSON, L. ELANDER, A. BLOMQVIST, D. ENGBLOM
Linköping Univ., Linköping, Sweden

Abstract: Inflammation-induced anorexia seems to be mediated both by PGE_2-dependent and independent pathways. Thus, the loss of appetite elicited by interleukin (IL)-1β is attenuated in mice with deletion of microsomal prostaglandin E synthase-1 (mPGES-1), the terminal inducible PGE_2 isomerase, whereas such deletion has no effect on the anorexia elicited by bacterial wall lipopolysaccharide (LPS). Furthermore, LPS-induced anorexia has been reported be dependent on melanocortin receptors, known to be critical for energy homeostasis.
In a series of experiments we have further examined in C57Bl/6 mice the components of the signaling pathways engaged by these two immune stimuli. Pretreatment with the unselective cyclooxygenase (Cox) inhibitor indomethacin or the Cox-2 inhibitor parecoxib, given intraperitoneally (i.p), but not the Cox-1 inhibitor SC 560, attenuated the anorexic response to LPS. Also when administered intracerebroventricularly, indomethacin reduced the LPS-induced hypophagia. Deletion of the MC4-receptor had no effect on the LPS-induced anorexia.
The IL-1β-induced anorexia was attenuated in mice with selective deletion of the EP_4-receptor in neural cells, but unaffected in mice lacking EP_1-, EP_2- or EP_3 receptors.
Taken together with previous observations, these findings show that LPS-induced anorexia is dependent on Cox-2, but not on mPGES-1, and that the signaling pathway is independent of MC4-receptors. The IL-1β-induced loss of appetite seems at least partly to be dependent on PGE_2 and its binding to EP_4-receptors. These results further support the notion that distinct prostanoids may elicit the anorexic response to LPS and IL-1β, respectively.

Title: Neonatal inflammatory pain increases food intake and body weight in adulthood and impairs hippocampal-dependent memory

Authors: *Y. OGAWA[1], N. C. VICTORIA[1], A. Z. MURPHY[2], M. B. PARENT[3]
[1]Neurosci. Inst., [2]Dept. of Biology, Neurosci. Inst., [3]Dept. of Psychology, Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Each year in the United States, over 500,000 infants are born prematurely. Preterm infants spend on average >2 weeks in the neonatal intensive care unit, where they undergo an average of 14 painful and inflammatory procedures each day, including repeated heel lances, endotracheal intubation, and respiratory and gastric suctioning. The hippocampus is a brain region important for learning and memory and is exquisitely vulnerable to the effects of stress. We have shown previously that neonatal injury decreases hippocampal glucocorticoid receptor expression and impairs hippocampal-dependent memory in adult rats. Given extensive evidence implicating the hippocampus in food intake, we hypothesized that neonatal injury also disrupts food intake in adulthood and that these effects are caused, at least in part, by hippocampal-dependent memory deficits. To test this, Sprague-Dawley rats were given an intraplantar injection of the inflammatory agent carrageenan (1%; edema 24-72 hrs) on the day of birth (Postnatal Day; PN0). Control rats were handled in an identical manner. In adulthood (PN232), food intake behavior and memory in the spatial water maze were measured. Our preliminary data indicate that a single injury on PN0 increased weight gain and decreased the satiety ratio, a measure of the interval between two meals. Interestingly, this effect was only observed in rats that had poor memory scores in the water maze task. These data are the first to demonstrate neonatal inflammatory pain disrupts energy intake and body weight in adulthood and that this effect is related to neonatal inflammatory pain-induced attenuation of hippocampal-dependent memory function.

Title: Neuronal tract tracing of a pathway relaying energetic signals originating in ependymocytes of the lower brainstem

Authors: *C. DEURA, S. MINABE, Y. UENOYAMA, K.-I. MAEDA, H. TSUKAMURA
Nagoya Univ., Nagoya, Japan

Abstract: Energy deficiency causes the suppression of reproductive functions and induction of feeding behaviors. In fact, food deprivation induced suppression of gonadal function in several mammalian species. We have previously suggested that the ependymocytes of the lower brainstem have a possible role in glucose sensing to regulate reproductive functions and food intake. It has also been demonstrated that the malnutrition-induced suppression of gonadotropin secretion is mediated by noradrenergic inputs to the hypothalamic paraventricular nucleus (PVN) from noradrenergic neurons of A2 region in the solitary tract nucleus (NTS). The aim of the present study is to test whether malnutrition-induced suppression of reproduction and feeding is mediated by neural pathway originating in ependymocytes projecting to the PVN through A2 noradrenergic neurons. To this end, wheat-germ agglutinin (WGA), a transsynaptic tracer, was injected into the fourth ventricle (4V) in adult Wistar-Imamichi male rats. These animals were perfused with 4% paraformaldehyde 48 h after WGA injection. Immunohistochemistry was performed to detect WGA in ependymocytes and noradrenergic neurons with specific antibodies for WGA, an ependymal marker vimentin and a noradrenergic neuronal marker dopamine β-hydoroxylase. WGA immunoreactivities were found in vimentin-immunopositive ependymocytes of the 4V and the central canal (CC), suggesting that ependymocytes have taken up WGA from the ventricular lumen. WGA signals were also detected in DBH-immunopositive neurons in the A2 region as well as magno- and parvocellular neurons in the PVN. These results indicate that brainstem ependymocytes connect to PVN through A2 noradrenergic neurons and suggest that the energetic signals were transduced from the ependymocytes to the hypothalamus via A2 noradrenergic pathway.

Title: Intraperitoneal LPS injection leads to hypothalamic AMPK dephosphorylation

Authors: D. C. V. VITORINO[1], *G. F. ANHE[2], R. M. MOURA[1], L. A. V. VELLOSO[1], E. A. R. R. ROMAN[1], C. E. N. NUÑEZ[1], D. S. R. RAZOLLI[1], G. A. S. SANTOS[1], M. A. T. TORSONI[1]
[1]Unicamp, Campinas, Brazil; [2]Dept. of Pharmacol., State Univ. of Campinas, Campinas, Brazil

Abstract: Aim:
AMP-activated protein kinase (AMPK) has long been known by its role in regulating the energetic metabolism in several tissues. Currently, researches have focused the role of AMPK on inflammatory mechanisms, raising the possibility that the kinase plays a crucial role in events triggered by acute endotoxemia. The presence of pathogenic organisms can lead to an increase in energy expenditure and satiety through toll like receptor-4 activation and inflammatory cytokine expression. Thus, AMPK modulation following the TLR-4 activation could be an important event related to several metabolic diseases as obesity and type 2 diabetes. Therefore, the aim of this study is to evaluate the effects on hypothalamic AMPK pathway following acute injection of LPS.
Methods:
Swiss male mice were submitted to stereotaxic surgery to implant of guide cannula into the lateral ventricle. A specific inhibitor of TLR-4 was administered via intracerebroventricular (ICV) and the endotoxin lypopolyssaccharide (LPS) was administered via intraperitoneal (IP) (1 mg/Kg). Four hours later, the animals were killed by decapitation and the hypothalamus was quickly removed and stored at -80ºC. All blood samples were centrifuged and the plasma stored. The plasmatic cytokines were determined by the ELISA procedure and the protein analysis by western blot. Glucose oxidase method and immunofluorescence assay were also performed.
Results:
The LPS treatment significantly reduced AMPK phosphorylation in the hypothalamus with concomitant increase in the plasmatic levels of TNF-α and IL1β, which was not prevented by the use of the TLR4 inhibitor. Blood glucose in LPS-treated animals was increased by 3 fold either in presence or absence of the icv inhibitor, when compared to control group ($p<0.05$). Besides, the inhibitor use per se did not alter de blood glucose compared to control group.
Conclusions:
AMPK dysregulation has been linked with obesity and metabolic syndrome. Hypothalamic AMPK plays important role in the satiety signal and energy expenditure, two events that can be damaged by model of sepsis and obesity. The present results have showed that ip systemic injection with LPS decreased the AMPK activation in fasted mice, which was followed by an increase in the circulating proinflammatory cytokines, suggesting therefore that the LPS-induced hypothalamic AMPK activity might be influenced by endogenous production of cytokines.

Title: Assessment of the subjective sleep quality in an elderly mexican population using the pittsburgh sleep quality index and its association with depressive symptoms

Authors: *M. M. MELENDEZ[1,2], A. GALLEGOS[3], G. VALDEZ GONZALES[3], M. LOPEZ BRAMBILA[3], E. AGUILAR BUSTOS[3], R. CAMACHO SOLIS[3]
[1]VENUSTIANO CARRANZA, UNAM / IAPA-DF, MEXICO DF, Mexico; [2]Direction executive research and evaluation, [3]research, IAPA DF, Mexico df, Mexico

Abstract: Mexican population is getting older. In 2010 people with more than 65 years old represents 6.2 % of the total population and in 2020 is expected that it will grow to 8.5 %, in 2030 it could reach 12.5 %. Indeed, life expectancy among Mexican people has increased to 75.4 years old (73.1 years in men and 77.8 years in women). This data show the challenge we will confront and the urgent need of programs to attend this new elderly population. Among these needs are included economic security and health care. Many individuals will face the risk of having at least one chronic disease. Moreover, emotional health is also very important, such as symptoms of depression, may significantly reduce the likelihood that elderly patients will receive preventive health services. Also, depressive symptoms are correlated with sleep quality changes and previous research has shown that sleep quality deteriorates with aging. Therefore, the aim of this study was to determine the prevalence of subjective sleep quality in an elderly Mexican population using the Pittsburgh Sleep Quality Index and a depressive symptoms test. The sample was taken among the men and woman with more than 65 year old living in Mexico City.We analyzed sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbance, use of sleeping medication and daytime dysfunction in this population. In addition, a Pearson correlation was made
with the depressive symptoms. The results show that we need to be prepared todeal with increasing disturbances in sleep quality and emotional disorders among elderly people, not only

in Mexico, but around the world. This view requires intervention at community and family levels, because none of this issues are isolated but in interaction with others.

Title: Markov modeling of sleep-wake dynamics for applications in neurotherapy

Authors: F. YAGHOUBY[1], T. ZHANG[2], M. STRIZ[2], K. D. DONOHUE[3], B. F. O'HARA[2], *S. SUNDERAM[1]
[1]Ctr. for Biomed. Engin., [2]Dept. of Biol., [3]Electrical and Computer Engin., Univ. of Kentucky, Lexington, KY

Abstract: Understanding the consequences of genetics, degenerative neural disorders, or acute neural injury on behavior involves extensive screening via sleep-wake and cognitive analysis of animal models. However, convenient metrics that track sleep-wake dynamics over time_beyond simplistic measures such as the percent time spent in each state (Wake, REM, non-REM) or mean bout duration_are lacking. Here, the utility of hidden Markov models (HMMs) estimated from invasive (EEG, EMG) and noninvasive (motion) physiological measurements in mice for tracking progressive changes in sleep-wake dynamics is investigated.
With IACUC approval, mice were surgically implanted with EEG/EMG preamplifiers and placed in cages equipped with piezoelectric motion sensors on the floor. The “piezo” signal discriminates sleep from wakefulness based on muscle activity, and senses thoracic movements associated with breathing, which is less regular in REM than in non-REM sleep. Piezo features that convey energy and breathing regularity can potentially be used to discriminate these stages of sleep. An HMM was used to sequence EEG/EMG data in 4s windows into REM, non-REM, and Wake states; at its heart is a 3x3 matrix representing the probabilities of transitions between the three states independent of state history. HMMs were estimated separately from EEG/EMG and piezo features every four hours. The accuracy of piezo HMM estimates was validated against HMMs estimated from EEG/EMG--the gold standard for sleep scoring--using a confusion matrix analysis. Trends in HMM properties were inspected to track progressive

changes in behavior such as circadian variation and recovery from surgery.
HMMs were able to track sleep-wake state with reasonable accuracy from continuous EEG/EMG measurements. HMMs estimated from piezo features alone were similar to HMMs based on EEG/EMG, except that REM sleep may be overestimated. The trace Tn of the HMM's transition matrix was used to estimate the probability that any state will persist uninterrupted. After surgery, Tn followed a decreasing trend without distinctive features for a few days; but a week later, Tn showed pronounced circadian rhythmicity indicative of normal sleep and behavior. This study suggests that HMMs estimated from physiological measurements could provide quantitative behavioral correlates of neural disorders as well as recovery from brain injury. We intend to further model the effects of interventions such as sensory or electrical stimulation on mouse sleep regulation and dynamics, with the end goal being a novel framework for dynamic programming of neurotherapy.

Title: Improved phenotyping and QTL analysis of sleep and wake traits in mice using a non-invasive, high-throughput piezo system

Authors: T. ZHANG[1], M. STRIZ[1], D. GOLDOWITZ[4], K. D. DONOHUE[2], E. J. CHESLER[5], K. M. HAMRE[6], *B. F. O'HARA[3,1]

Abstract: Sleep and wake are influenced by genetic and environmental factors, but little is known about the specific genes involved in variation of sleep:wake parameters. Traditional sleep

phenotyping has been limited by the invasive and labor-intensive nature of EEG/EMG methods, which creates a bottleneck for high-throughput genetic studies, such as quantitative trait locus (QTL) analysis. This study utilized a noninvasive piezoelectric sleep-wake activity monitor for high-throughput screening. The system has demonstrated a 90-95% accuracy compared to EEG/EMG and human observation, and has already proven successful in screening over two thousand mice for sleep and wake traits, including BXD recombinant inbred mice and a large population of pre-collaborative cross (CC) mice during multiple generations of inbreeding. The present study employs the BXD piezo data to further evaluate sleep:wake parameters to find QTLs associated with the temporal dynamics of sleep, environmental influences, and other variables.

Over 450 female & male mice from 54 lines of expanded BXDs were individually housed in a 12h:12h light:dark cycle. Mice were recorded in the piezo system for 4-5 days to monitor their sleep-wake behavior. For data analysis, hourly sleep:wake parameters, including percent sleep and median bout length, were extracted from the raw data. The first day recordings were classified as an acclimation day and analyzed separately. For the following 3 days, 24 hours were divided into 3 hour segments and 6 hour segments according to the Zeitgeber Time. Percent sleep one hour ahead and after lights on/off were treated as specific traits. Interval mapping was performed using WebQTL to identify general QTLs that influence the sleep:wake parameters within a specific time period. This analysis confirmed several previously reported QTLs and identified several novel loci associated with sleep and wake. In addition, it suggested that QTLs associated with total sleep time overlap QTLs associated with bout length, which is expected and strengthens the results, but was not clear in the previous studies. Additionally, using the recordings of the first day, which were omitted in previous analyses, several QTLs were found that contribute to strain differences in sleep in novel environments.

To enhance and expand this phenotyping system, work has been done to develop a 3-state classifier (REM, nonREM, wake) (See adjacent poster “Markov modeling of sleep-wake···”) in addition to other classifiers that distinguish quiet wake, grooming and locomotor activities. Using these new algorithms, more traits and QTLs, and the dynamic interaction of these traits and loci, can be examined.

Title: Sleep-wake cycle in laboratory and domestic cats

Authors: *L. B. GRAND, S. CHAUVETTE, I. TIMOFEEV
Le Ctr. De Recherche Univ. Laval Robert-Giffard (CRULRG), Quebec, QC, Canada

Abstract: Previous studies conducted on cats in isolated small size chambers demonstrated a very fragmented pattern of sleep. It was unclear to what extent these experimental conditions influenced the exact pattern of sleep-wake alterations in these species.
We examined activity patterns of 4 cats kept in the animal facility and 4 cats in the domestic environment. Laboratory cats were housed in colonies under a standardized environment in which employees had defined access to the room. Domestic cats lived together with their owners. Activities of all animals were recorded with an accelerometer. In two laboratory cats, continuous accelerometer, video and electrophysiological (wireless) recordings were carried out for 1 month.
In laboratory cats an increased activity was observed: (1) about 2 hours before lights-on, (2) at the time of entries of personnel in the experimental room and (3) at the onset of dark period. The increased activity lasted 2-3 hours. Occasional periods of activity were found at other times. The overall measured inactivity level was 60%. Electrographic data indicate that laboratory cats slept 50-55% of time. Therefore, activity measures predicted sleep with 87% accuracy. Domestic cats were usually active between 4 and 9 am and 5 and 8 pm although occasional periods of activity could occur at other times. Similar to laboratory cats, the inactivity periods in domestic cats occupied 65% of the 24-hour period of time.
We conclude that domestic and laboratory cats have very similar profile of activity-inactivity. Within the 24-hour period, cats have 2 periods of increased activity: before lights-on and after lights-off; each period lasting 2-4 hours. Laboratory cats sleep 50-55% of the time suggesting that domestic cats sleep 55-60% of the time. During the long sleep period, the cats often have brief periods of waking. Parallel recordings of accelerometer and electrographic activities show that the accelerometer alone is a useful tool for analyzing the sleep-wake cycle of cats.

Title: Lesions of the putamen elicit motor disorders in sleep

Authors: *Y.-Y. LAI, J. M. SIEGEL
Psychiatry, UCLA/VAGLAHS Sepulveda, NORTH HILLS, CA

Abstract: Muscle activity across the sleep-wake cycle is state-dependent; normally high in wake, low and regular in slow wave sleep (SWS), and atonic in rapid eye movement (REM) sleep. Over the past decades, studies of brain control of motor activity have been focused on wake and REM sleep. However, modulation of motor activity during SWS remains unclear, despite the fact that abnormal motor activity in SWS has been reported in the majority of sleep-related motor disorders. More than 10% of the population has periodic leg movements (PLM) in sleep. Our previous study showed that cats with lesions of the substantia nigra pars reticulata (SNR) generate PLM in sleep. The SNR receives GABAergic projections from the putamen via direct and/or indirect pathways. Abnormalities of the putamen have been reported in human restless legs syndrome patients, who have PLM in wake and in SWS. In this study, we show that neurotoxic lesions of the putamen also increase motor activity in SWS in the rat. Eight young adult Sprague-Dawley rats were used, 5 for controls and 3 for the putamen lesion group. Under isoflurane anesthesia, electrodes were implanted in the skull to record EEG. Flexible wires were implanted in the hindlimb and neck musculatures to record muscle activity. Experimental rats were given 50 nl NMDA (0.5 M) injections into the putamen, bilaterally (2 rats) or unilaterally (1 rat). Sleep recordings were performed after the animal recovered from the surgery. No signs of tremor, rigidity, or bradykinesia in wake were observed in the lesioned animals. However, motor hyperactivity in SWS was observed in all the lesioned rats. The average PLM index (total number of PLM/total time of SWS/24 hour) of lesioned rats was 37.3 ± 10.3, while the PLM index of the normal rats was 1.8 ± 1.7. The sleep pattern was not changed in the lesioned rats (minute/24 hour; wake, control rats: 619.4 ± 59.7, lesioned rats: 603 ± 99.1; SWS, control rats: 714.1 ± 43.5, lesioned rats: 730.8 ± 102.2; REM sleep; control rats: 106.5 ± 5.7, lesioned rats: 106.1 ± 6.4). No differences were seen in the sleep pattern or PLM activity between rats which received bilateral putamen lesions and the rat that received a unilateral lesion. We hypothesize that, like the SNR, the putamen also plays an important role in the control of motor activity in sleep.

Title: Sleep stage changes connectivity in human cortices: A cortico-cortical evoked potential study

Authors: *K. USAMI[1], R. MATSUMOTO[1], T. HITOMI[2], K. KOBAYASHI[1], A. SHIMOTAKE[1], T. KUNIEDA[3], N. MIKUNI[5], S. MIYAMOTO[3], H. FUKUYAMA[4], R. TAKAHASHI[1], A. IKEDA[1]
[1]Neurol., [2]Resp. Med., [3]Neurosurg., [4]Human Brain Res. Ctr., Kyoto Univ. Grad. Sch. of Med., Kyoto, Japan; [5]Neurosurg., Sapporo Med. Univ., Sapporo, Japan

Abstract: **Introduction:** How the connectivity of brain network changes with sleep stage remains to be elucidated for better understanding of normal information processing or propagation of epileptic discharges during sleep. By directly stimulating a part of the cortices during sleep and by recording cortico-cortical evoked potentials (CCEPs) that emanate from the adjacent and remote cortices, we could trace cortico-cortical connections *in vivo*. The parameters of CCEPs [generally consisting of the 1st sharp (N1) and the 2nd slow (N2) negative components] should reflect the degree of connectivity or interaction between stimulus and recording sites. Making use of its excellent spatio-temporal resolution, we attempted to investigate how sleep modulates cortico-cortical connections in human brain. We hypothesized that 1) CCEPs change during sleep and 2) the degree of
modulation of CCEPs differs between the primary sensorimotor cortex (Pr) and the non-primary association cortex (NPr).
Methods: Subjects were 8 patients with intractable partial epilepsy who underwent invasive presurgical evaluation with chronic implantation of subdural electrodes (IRB No. 443). Repetitive single-pulse electrical stimulation (1 Hz) was applied to cortical surface away from the epileptic focus, and CCEPs were recorded by averaging electrocorticogram time locked to the stimuli, sequentially at different sleep stages (W: awake, L: stage I-II, S: stage III-IV, and R: REM) that were judged from the simultaneous scalp EEG/EOG recording. The modulation of connectivity was assessed with the size and latency of N1/N2 component of the

adjacent or remote CCEPs that were spatio-temporally isolated from their neighborhood.
Results: A total of 11 pairs of electrodes were stimulated (1-2 stimulus sites per patient), and adjacent or remote CCEPs were identified at 28 electrodes among patients. Sleep stage significantly changed CCEP parameters (N1 and N2 size, N1 latency). Significant change was observed between W vs. L and/or S. We then assessed the degree of
CCEP modulation in reference to the stimulus-recording sites pair [Pr-Pr (n=5 pairs) vs. Npr-Npr (n=20)]. Analysis of N1 size change demonstrated an inverse relationship between Pr and NPr cortices; namely, as compared with stage W, N1 at stage L became larger in NPr but smaller in Pr. The behavior of CCEPs at stage R was similar to that at stage W regardless of cortical architecture.
Conclusion: Cortico-cortical connectivity changes once patients fall asleep. The degree of connectivity change most likely depends on the sleep stage [awake&REM vs. non-REM (L&S)] and cortical architecture (primary vs. non-primary cortex).

Title: Transcranial electrical stimulation accelerates sleep homeostasis in humans

Authors: D. REATO[1], F. GASCA[2,3], A. DATTA[1], M. BIKSON[1], L. MARSHALL[3,4], *L. C. PARRA[1]
[1]Biomed. Engin., City Col. of New York, NEW YORK, NY; [2]Inst. for Robotics and Cognitive Systems, [3]Grad. Sch. for Computing in Med. and Life Sci., [4]Dept. of Neuroendocrinology, Univ. of Lübeck, Lübeck, Germany

Abstract: Sleep pressure is reflected in the power of slow-wave activity: it is high after extended wakefulness and gradually decays in the course of the night. Transcranial stimulation with slow-

oscillating currents can entrain electro-encephalographic slow-wave oscillations (SWO) and transiently increase their power. Here we show in humans that 25 minutes of stimulation attenuates the decay of SWO in the remainder of the night. A computational model of up/down-state transitions underlying these SWO predicted the entrainment to a specific phase of the oscillating stimulation. The model also shows a preponderance for increased firing rates during stimulation. This increased firing rate could accelerate homeostatic synaptic downscaling resulting in reduced SWO in the hours of nocturnal sleep after stimulation. To test these predictions we analyzed human EEG data recorded after transcranial electrical stimulation in sleep and found attenuated decay of power and spatial coherence of SWO. Combining the results from a Finite-Element Model (FEM) of electrical stimulation, that simulates anatomically accurate currents distributions that account for folding of human cortex and the computational model of up/down-state transitions, we were able to predict the magnitude and spatial distribution of the effects of electrical stimulation in the human EEG experiments. These combined experimental and modeling results show how electric stimulation can accelerate synaptic homeostasis, and thereby influence a putative processes of sleep regulation. The ability to accelerate the homeostatic function of sleep may have important practical implications.

Title: Enhancing slow waves using acoustic stimuli

Authors: *B. A. RIEDNER, M. BELLESI, B. K. HULSE, G. SANTOSTASI, F. FERRARELLI, C. CIRELLI, G. TONONI
Psychiatry, Univ. of Wisconsin - Madison, MADISON, WI

Abstract: Increasing evidence suggests that electroencephalographic (EEG) sleep slow waves may perform a key role in sleep’s restorative function, perhaps mediating critical cellular benefits of sleep on the brain. If so, the ability to potentiate slow waves during sleep might mitigate the detrimental effects of sleep loss and could be particularly impactful for a chronically sleep-deprived society. Previous work from our laboratory has identified acoustic stimulation as

a promising non-pharmacological means for increasing slow waves (Riedner et al., 2010). Here, we present data further demonstrating that tones can enhance slow waves when administered during sleep. Six subjects (5 males, ages 21 - 28) were recorded with a six-channel EEG montage that included chin electromyography and two electro-oculographic channels. Blocks of 15 brief tones (2000 Hz, 50 ms duration) were played using headphones or speakers (ON blocks, 1 sec inter-tone interval) during deeper stages of NREM sleep preceded and followed by 15 seconds without stimulation (OFF blocks). ON blocks were then contrasted with the adjacent OFF blocks in order to make valid comparisons given the moment to moment changes in sleep depth. Stimulation blocks were delivered automatically using a software algorithm designed to detect sleep based on the ongoing EEG and importantly to adjust tone intensity based on sleep depth. Subjects received an average of 148 stimulation blocks (range 103 - 196) during N2 and N3 sleep. All subjects showed an increase in slow wave band-limited power (0.5 - 4 Hz) during ON compared to OFF blocks, ranging from 6 - 22%. Power in other frequency ranges were not statistically different from each other, suggesting that tones were not causing arousals or affecting other sleep EEG rhythms (i.e. spindles). The increase in slow waves resulting from the stimulation was apparent regardless of sleep cycle or whether the stimulation block occurred in N2 or N3 sleep. These results confirm the viability of using automatically administered acoustic stimulation to non-pharmacologically increase slow waves. Future work will examine the reliability of this effect and investigate alternative stimulation protocols, as well as determine whether stimulation enhanced sleep produces restorative benefits.

Abstract: In 2010, a new methodology called high resolution electroencephalography (HR-EEG) for mouse brain was introduced in Journal of Neurophysiology (Choi JH, Koch KP, Poppendieck W, Lee M, Shin HS (2010) High resolution electroencephalography in freely moving mice. J Neurophysiol 104: 1825-1834; Lee M, Kim D, Shin H-S, Sung H-G, Choi JH (2011) High-density EEG Recordings of the Freely Moving Mice using Polyimide-based Microelectrode. J Vis Exp: e2562). By combining this new technique with conventional local field potential recording in thalamus, we revisited the sleep wave including sleep spindle, K-complex, and slow-wave sleep oscillation in the viewpoint of the generation, propagation, and termination of these waves. We analyze the spatio-temporal patterns of the sleep waves and performed causality study between sleep waves in cortex and thalamus. We also analyzed the structures of sleep wave under the condition of acute sleep deprivation as well as chronic sleep deprivation.

Title: Monitoring neuronal activity with a new calcium indicator in D. melanogaster

Authors: L. BAI[1], S. DOSHI[2], W. JOINER[3], *A. SEHGAL[1]
[1]HHMI/Perelman Sch. of Med. At the Univ. of Pennsylvania, Philadelphia, PA; [2]Neurosci. Grad. Group, Univ. of Pennsylvania, Philadelphia, PA; [3]Dept. of Pharmacol., UCSD, San Diego, CA

Abstract: The fruit fly Drosophila melanogaster has been an extremely useful model for understanding genetic and molecular mechanisms underlying circadian control of rest:activity and other rhythmic behaviors. A related effort is directed towards understanding the molecular

mechanisms of sleep-wake regulation. Most studies classify sleep-like states in the fly based solely upon behavioral locomotion patterns as, thus far, it is not possible to record electroencephalograms (EEGs) in the fly. Monitoring brain activity in vivo should help greatly to define sleep/wake states at the brain/neuronal level in the fly, just as EEGs do for mammals. Genetically encoded calcium indicators (GECIs) are becoming crucial tools for monitoring neuronal activity in vivo. However, mainstream GECIs are engineered with fluorescent proteins and thus require laser excitation, which could potentially have direct effects on sleep-wake and/or affect circadian control of behavior. To overcome this caveat, we designed a new GECI that reports calcium transients with bioluminescence changes. We are able to monitor bioluminescence from whole dissected brains of flies that express this GECI either pan-neuronally or in various brain regions. In ongoing experiments we are restricting expression of the GECI to either wake- or sleep-promoting neurons and attempting to correlate neural activity with behavioral activity. This new GECI may provide a valuable tool for characterizing neuronal circuits underlying different behavioral paradigms.

Title: Slow waves and sleep consciousness

Authors: *F. SICLARI, J. J. LAROCQUE, B. R. POSTLE, G. TONONI
Dept. of Psychiatry, Univ. of Wisconsin, Madison, WI

Abstract: *Aims and background*: Dreaming is a particular form of consciousness that occurs during sleep. Although mental activity is most frequently and vividly recalled when awakening from REM sleep, it is also reported in up to 80% of Non-Rem (NREM) sleep awakenings. Slow waves, the hallmark of NREM sleep, reflect a slow oscillation of cortical neurons between up

and down states. It has been suggested that the brain's capacity to integrate information and generate conscious experiences is reduced whenever the brain is in such a bistable state. We aimed at determining whether slow waves are a negative predictor of sleep consciousness and whether machine-learning techniques can reliably distinguish between periods with and without mental activity.
Methods: Two healthy participants each underwent six overnight high density-EEG recordings with 256 electrodes. They were awakened by a computerized sound at 15-20 minute intervals and questioned for the presence or absence of sleep consciousness. Recall without content ("I was experiencing something but do not remember what") was considered separately. A time frequency transform of the EEG signal in the two minutes preceding the awakening was performed to obtain power in the 1 to 4.5 Hz frequency band. Multivariate pattern analysis (L2-regularized logistic regression) was performed for the EEG signal within the delta band in the 10 seconds prior to waking.
Results: 253 questionings were performed (3% in wake, 30% in stage NREM1, 47% in NREM2, 26% in NREM3 and 26% in REM sleep). Recall with content was reported in 76 (41%) of the 185 awakenings obtained in stages N2 and N3. Awakenings yielding sleep consciousness reports were associated with significantly lower frontal delta power over all electrodes compared to awakenings without consciousness ($p<0.001$). Pattern classification predicted the presence of sleep consciousness with above chance accuracy.
Conclusion: Our results suggest that the brain's capacity to generate
conscious experience during sleep is reduced in the presence of slow waves. Initial analyses indicate that machine-learning techniques can predict the presence of sleep consciousness.

Title: Sleep spindles and sleep consciousness

Authors: *J. J. LAROCQUE, F. SICLARI, B. R. POSTLE, G. TONONI
Neurosci. Training Program, Univ. of Wisconsin - Madison, Madison, WI

Abstract: Introduction: Sleep is associated with a reduction in the level of consciousness. However, reports of dreaming, or conscious experience during sleep, can be elicited upon waking from any stage of sleep. Here, we explored the influence that sleep spindles - 12-15 Hz oscillations arising from connections between thalamus and cortex - may exert on conscious experience during sleep. Reasoning that the capacity of the thalamocortical system to integrate information and generate conscious experience is compromised by the highly synchronized activity of sleep spindles, we predicted that sleep spindles would be associated with reduced reports of sleep consciousness.
Methods: We collected high-density electroencephalographic (EEG) data from two subjects for six nights each. Subjects were awakened with a tone every 15-20 minutes, and sleep consciousness was assessed with a questionnaire. To the primary question, “What was going through your mind immediately prior to the tone?” subjects could respond positively (with a report of the content of their sleep experiences) or negatively (denial of any sleep experiences). Ambiguous responses, in which sleep consciousness was reported without any recall of content, were considered separately. A time-frequency transform was applied to the EEG data preceding each waking, and analyses were performed on the resultant spectrogram at each electrode. We also calculated additional measures of spindle activity, including number of spindles, duration of spindles (integrating across all spindles present in the two minutes preceding waking), and time since last spindle.
Results: In stage 2 and 3 non-REM sleep, power in the spindle range (12-15 Hz) was significantly lower during epochs preceding positive reports of sleep consciousness compared with those preceding negative reports. This effect was strongest at bilateral frontal and central parietal electrodes. Additionally, for epochs preceding reports of sleep consciousness, spindle power was negatively correlated with the subjective estimate of the length of the conscious experience. Initial analyses also suggest that in right frontal electrodes, fewer spindles, shorter spindle duration, and longer time since last spindle all were associated with longer duration of conscious experience during sleep.
Conclusion: During non-REM sleep, 12-15 Hz spindles are negatively associated with incidence of sleep consciousness. Importantly, sleep spindles also correlate with quantitative features of sleep consciousness, such as subjective length of the experience. This provides strong support for the influence of spindle activity on sleep consciousness.

Title: Basal ganglia functional connectivity in human NREM sleep

Authors: *C. GOH[1], R. KANAI[1], V. WALSH[1], O. JOSEPHS[2]
[1]Inst. of Cognitive Neurosci., London, United Kingdom; [2]Wellcome Trust Ctr. for Neuroimaging, London, United Kingdom

Abstract: An emerging literature implicates the basal ganglia (BG) in the control of sleep-wake (S-W) behavior. Dopaminergic modulation of the BG and BG-dependent sites may exert sleep stage-specific influence on cortical activity levels. We measured whole-brain activity by functional MRI during human non-rapid eye movement (NREM) sleep, and show that functional connectivity (fc) between BG sites (striatum (caudate nucleus, putamen), globus pallidus (GP)) and the cortex differs across NREM sleep stages. Compared to wake, in both light and deep sleep the GP shows greater fc with the insular cortex, but less fc with primary motor and anterior temporal areas, while the striatum shows more coupling with primary motor and lateral occipital areas, and the middle temporal gyrus. In contrast to the GP, the striatum has greater fc to the insular cortex during light sleep, relative to wake. Additionally, the GP is more coupled to frontal regions during deep sleep. A possible explanation for increased coupling to the motor cortex during sleep is possibility is that increased functional connectivity reflects a progressive loss of inhibitory cortical influence by the basal ganglia. Furthermore, the greater fc between GP and frontal regions found during deep sleep is discussed in the context of the GP's putative role in the initiation of slow oscillations.

Title: Anatomical connectivity supports functional community structure in macaque cortex

Authors: *K. SHEN[1], G. BEZGIN[1], R. M. HUTCHISON[2,3], J. S. GATI[3], R. S. MENON[2,3], S. EVERLING[2,3], A. R. MCINTOSH[1,4]

Abstract: Computational and empirical neuroimaging studies have suggested that the anatomical connections between brain regions largely constrain their functional interactions. Given that the large-scale organization of functional networks is determined by the temporal relationships between brain regions, the structural limitations may extend to the global characteristics of functional networks. Here, we explored the extent to which the functional network community structure is determined by the underlying anatomical architecture. We directly compared macaque functional connectivity (FC) assessed using spontaneous blood-oxygen-level-dependent functional magnetic resonance imaging (BOLD-fMRI) to anatomical connectivity derived from macaque axonal tract tracing studies. Consistent with previous reports in both humans and monkeys, we observed strong FC both within and across hemispheres. FC increased with increasing strength of anatomical connection and FC was also present between regions that had no direct anatomical connection. We observed high similarity between each region's FC and its anatomical connectivity. Notably, partitioning of the functional network was supported by dense intra-modular bidirectional anatomical connections that were not present when considering the non-partitioned network. Taken together, our data directly demonstrate that the observed FC in resting-state fMRI is dictated by the underlying neuroanatomical architecture. Importantly, we show how this architecture contributes to the global organizational principle of functional specialization.

Title: Local clock in the iris of the turtle?

Authors: G. S. TROUTMAN, K. NIOTIS, *J. R. DEARWORTH, Jr.
Lafayette Col., Easton, PA

Abstract: Studies done in our laboratory suggest that the degree of constriction by the pupil in response to light in turtles can be associated with their circadian rhythm. After turtles are subjected to the condition of constant darkness, their pupillary light reflex is diminished. However, the response of the pupil without feedback from the brain (the photointrinsic iris response) and how it can be affected by different photoconditions is unknown. This study explored whether there is a connection between the visual processing done for circadian rhythms and the photointrinsic iris response. This was done by subjecting turtles over long periods (≥10 days) to three different photoconditions (12 hours of light with 12 hours of dark = 12L:12D, constant light, and constant dark) and comparing their photointrinsic response from their enucleated irises. Turtles under control conditions (12L:12D) had a photointrinsic iris response that reduced the pupil size by ~14%. In contrast, the response in turtles in constant dark was less at ~4%, and the response was entirely eliminated in turtles exposed to constant light. These results suggest that the photoreceptive mechanism responsible for driving the photointrinsic iris response is influenced by prior photoconditions to which the turtles are subjected possibly regulated by a circadian clock.

Title: Auditory responses and stimulus-specific adaptation are largely preserved across NREM and REM sleep in rat primary auditory cortex

Authors: *Y. NIR[1], V. V. VYAZOVSKIY[1,3], C. CIRELLI[1], M. I. BANKS[2], G. TONONI[1]
[1]Dept. of Psychiatry, [2]Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI; [3]Dept. of Biochem. and Physiol., Univ. of Surrey, Guildford, United Kingdom

Abstract: Sleep entails a disconnection from the external environment, but to what extent signal propagation along ascending sensory pathways is preserved across vigilance states remains unclear. It has been suggested that the thalamus may not relay effectively sensory inputs to the cortex in sleep, but recent evidence challenges this view.
In this study, neuronal and LFP responses to sounds in rat primary auditory cortex were compared between wakefulness and sleep. Adult WKY rats were implanted with microwire arrays (~50 kΩ) in right A1 (n=6). After a week of recovery, sleep stabilization, and habituation to stimulation, acoustic stimuli were presented (free-field) in a sound-proof, acoustically-calibrated environment as rats spontaneously switched between vigilance states. In the first experiment, 24 sounds were presented pseudo-randomly with inter-stimulus intervals (ISIs) of 1250±250ms at 3 intensities (30,55,80 dB SPL). Stimuli included short (100ms) and long (600ms) tones, clicks and click-trains (duration = 500ms), more complex stimuli including environmental sounds and rat vocalizations (duration = 250-1000ms), as well as FM sweeps (0.5-2kHz, duration = 100ms) and 'chirp AM' tones [10kHz, f_{mod} = 20-200Hz, duration = 600 ms). In a second 'oddball' experiment, low (8kHz) and high frequency (45kHz) tones were presented frequently (90%) or rarely (10%) in a mixed and counter-balanced manner (ISIs = 750±100ms, 55 dB SPL). Local field potentials (LFPs), and single unit activity (SUA) were recorded continuously along with epidural EEG, EMG and video, and spike sorting was performed offline. Vigilance states were scored in 4s epochs on the basis of EEG, EMG, and behavior.
We recorded from a total of 520 units in A1 and quantitatively compared SUA across vigilance states. Trials categorized as wake, NREM or REM sleep showed robust differences in baseline LFP power spectra and neuronal discharges (e.g. firing rate in NREM was 80.5% of that in wakefulness, $p < 10^{-43}$). On average, both the selectivity and the magnitude of evoked SUA were comparable across wakefulness, NREM and REM sleep (differences < 8.1% between all states), and this was confirmed separately for onset, offset, and sustained responses. In the oddball paradigm, robust stimulus-specific adaptation (SSA) was observed following the onset of repetitive tones. SSA was similar in magnitude across vigilance states, suggesting that basic

deviance detection persists in sleep. These results support the notion that responses to external stimuli are preserved in primary sensory cortices across sleep. A functional disconnection may prevent activity to effectively drive high-order cortical regions.

Title: Embodied global network of consciousness

Authors: *T. YANAGAWA, N. HASEGAWA, N. FUJII
BSI, RIKEN, Wako Saitama, Japan

Abstract: How does the brain generate consciousness? A hypothesis suggests that there might be sustained neural interaction in ongoing activity, which supports stable continuity of consciousness and a drop of the network interaction will cause elimination of consciousness (Alkire et al. 2008). Based on the hypothesis, previous studies in functional imaging and electrophysiology indicated importance of the global network interaction in the brain to maintain the stable conscious state. Specifically the interactions between frontal and parietal regions and between thalamus and those regions were reported to be reduced during loss of consciousness (Boveroux et al. 2010, Ku et al. 2011). However, neural interactions in entire cortical network in awake/anesthetic-unconscious state have not been well investigated with high spatio-temporo-spectral resolution by using electrophysiological technique.
Here we estimated neural interactions by calculating spectral granger causality from electrocorticographic data recorded from entire lateral cortex in four macaques during awake and anesthetic conditions. Ketamine and Medetomidine were used for anesthetic agent. We revealed sustained neural interactions in alpha and beta band that was stable over days, but was lost in anesthetic condition. The neural interactions were found between/within a block of premotor-sensorimotor-parietal (PSMP) cortices, prefrontal and temporal cortex.
Previous studies showed that beta-band oscillation in PSMP reflects sensorimotor integration (Baker 2007). So we hypothesized that the sustained neural interaction in PSMP in beta-band during resting state may produce unified and continuous bodily sensation that is often called

body schema. To test the hypothesis we applied local anesthesia in forearm which disrupted the monkey's body schema on the forearm and found modulation of the neural interaction in the PSMP.
The results suggest that the PSMP integrates multimodal somatosensory-motor information and generates body schema that anchors cognitive processes to physical body resulting the stable embodied conscious state.

Title: Measuring the level of consciousness based on the amount of integrated information computed from electrocorticogram (ECoG) recordings in monkeys before and after anesthesia

Authors: *M. OIZUMI[1,2,3], T. YANAGAWA[2], S.-I. AMARI[2], N. TSUCHIYA[2,4,5], N. FUJII[2]

Abstract: Assessing the subjective conscious state of an organism based on the activity of the brain is an important issue in the clinical settings, yet it is one of the most challenging problems in neuroscience. The brain-based measure of the level of consciousness is most wanted in assessing the state of those who cannot speak (e.g., under anesthesia, in the vegetative state, etc) as has been suggested by recent studies that identified disadvantages in the conventional behavioral measures in assessing consciousness. Here we provide the results of our first step towards the goal of developing an empirical "consciousness meter" based on the real neuronal data.
One promising theory that allows us to quantify the level of consciousness is the information integration theory of consciousness proposed by Giulio Tononi. According to the theory, the level of consciousness corresponds to how much information is differentiated and

simultaneously integrated in the brain. In the theory, various forms of loss of consciousness are commonly explained as the drastic loss of the ability for the brain to integrate information. The measure proposed by the original theory, however, is intractable to compute in large systems. To cope with such intractability, some alternative measures that approximated the original one have been proposed. However, we found that these measures have some caveats, one of which manifests when neural activities are strongly correlated.
Here, we propose a yet another measure based on the concept of 'decoding', while keeping its applicability to real neural data. With this new measure, we quantified the amount of integrated information before, during and after anesthesia using the electrocorticogram (ECoG) recordings in 4 monkeys over 12 sessions. The ECoG data were simultaneously recorded from the surface of various cortical areas with 128 electrodes while the monkey subjects underwent a transition from an awake state to anaesthetized state. To separately evaluate the contribution of different frequency bands (delta, theta, alpha, beta, and gamma), we first applied the linear band-pass filter to the data and then computed the integrated information in each frequency band. We found that the integrated information computed in beta-band (12-30 Hz), but not in the other bands, decreased in a large amount after the injection of anesthetic drugs consistently across subjects and recording sessions. Our results suggest that our new measure of the integrated information based on the beta-band activity across the entire brain may be a promising candidate for the future development of the "consciousness meter".

Title: Altered glucokinase expression and function in identified GABA neurons in the nucleus tractus solitarius in mice with type 1 diabetes

Authors: S. MAIMAITI, K. C. HALMOS, P. GYARMATI, *B. N. SMITH
Dept Physiol, Univ. Kentucky, LEXINGTON, KY

Abstract: Type 1 diabetes is characterized uncontrolled hyperglycemia due to loss of insulin secretion from pancreatic beta cells. Effects on brainstem circuits of prolonged hyperglycemia

and hypoinsulemia have been documented, and GABA neurons in the nucleus tractus solitarius (NTS) express glucokinase and respond to changes in glucose concentration. Synaptic control of central vagal circuits is tightly regulated by glucose and displays plasticity in diabetic animals. Identified GABA neurons from mice that express GFP in a subset of inhibitory neurons (GIN mice; FVB-Tg(GadGFP)4570Swn/J) were targeted for whole-cell patch-clamp recordings. We tested the hypothesis that modulation of glucokinase activity would alter synaptic transmission in identified NTS GABA neurons and that this effect would be reduced in diabetic mice after 3-6 consecutive days of hyperglycemia. GIN mice (3-8 wk old) were fasted for 6 hrs before being injected with streptozotocin (STZ; 200mg/kg; i.p.) to induce hyperglycemia or vehicle (control). Blood glucose levels were monitored until the day of experimentation. In recordings from GABA neurons in control mice, application of the glucokinase-inhibitor glucosamine (GA; 5 μM) reversibly suppressed sEPSC frequency by 40 +/- 6% ($p<0.01$; $n=14$) within 5 min of application, with no effect on amplitude. In neurons from STZ-treated, diabetic mice, GA induced no effect on sEPSC frequency or amplitude ($p>0.05$; $n=6$). Pre-incubation of slices for 30 min with insulin (1 μM) failed to restore the effect of GA on sEPSC frequency in diabetic mice ($n=4$), suggesting the loss of effect was not due to deficiency of insulin-dependent protein trafficking. Quantitative PCR indicated a significant decrease in GCK expression in trimmed slices containing the dorsal vagal complex from STZ-treated mice versus controls ($p<0.05$). Results indicate that synaptic input to NTS GABA neurons is sensitive to glucokinase modulation and that this modulation is suppressed following several days of hyperglycemia, which coincided with glucokinase downregulation. Such modulation is consistent with the hypothesis that GABAergic neurons in the NTS are sensitive to glucose modulatory mechanisms that may contribute to autonomic dysregulation in metabolic disorders.

Title: Striatal vacht ko mice are hyperphagic and lean

Authors: *M. S. GUZMAN LENIS[1], X. DE JAEGER[1], M. G. CARON[2], M. A. M. PRADO[1], R. GROS[1], V. F. PRADO[1]
[1]Robarts Res. Inst., London, ON, Canada; [2]Howard Hughes Med. Inst., Durham, NC

Abstract: The balance dopamine (DA)/ acetylcholine (ACh) in dorsal striatum has a role in movement disorders such as PD. This balance is also important for motivational disorders. In the striatum (STR), cholinergic neurons seem to counteract the effects of DA. This has been also observed during feeding and satiety. DA in NAcc is thought to increases appetite, whereas an increase in ACh is thought to be related to the onset of satiety. In this regard, it has been reported that rats with cholinotoxic lesions in STR show lower body weight and increased food consumption. Also, ACh levels in the NAcc normally increase during a meal when feeding slows down and may peak when feeding stops. ACh also seems to modulate STR opioid mRNA expression. The STR is among the brain regions with the highest levels of opioid peptides and receptors. In the STR the opiod peptides dynorphin and enkephalin help activating food-directed behaviour regulated by the hypothalamic energy-sensing system. In our laboratory we have developed a novel mouse line where the vesicular ACh transporter (VAChT) has been specifically eliminated in the STR, resulting in the elimination of ACh release. In our effort to characterize this mouse line, we found that striatal VAChT KOs were leaner when compared to their littermate controls suggesting that ACh release in striatum might play a role in feeding behaviour. Using indirect calorimetry we found metabolic differences between young and adult striatal VAChT KO mice. Young animals are hyperactive and have increased respiratory exchange ratio (RER) during the light cycle and lower RER in the dark cycle. On the other hand, adult mice are hyperphagic and have increased RER, both during the light and dark cycle. Both group of animals show no changes in heat production and body temperature. They also have higher oxygen consumption and, interestingly, they sleep less. Young striatal VAChT KO mice show a better tolerance for glucose in the glucose tolerance test while adult mice show no difference when compared against controls. We also analyzed mRNA expression levels of preprodynorphin and preproenkephalin in the STR and VAChT expression levels in the hypothalamus and found no differences. Paradoxically, hypothalamic mRNA levels of MCH, Orexin, POMC and AgRP in adult striatal VAChT KO mice were not changed, while young mice showed a tendency for lower levels of POMC and increase levels of Orexin. Our data indicate that cholinergic tone in the STR participates in modulation of food intake. The study of the metabolic changes in our mouse line might offer new therapeutic perspectives for the treatment of obesity.

Title: Acute exposure of the mediobasal hypothalamus to β-amyloid peptide induces hepatic insulin resistance

Authors: *I. ARRIETA-CRUZ[1], R. GUTIÉRREZ-JUÁREZ[2]
[1]Inst. De Geriatría, Mexico City, Mexico; [2]Med., Albert Einstein Col. of Med., Bronx, NY

Abstract: Alzheimer's disease (AD) is the most common form of dementia and increasing age is the best known risk factor for the development of this disease. β-amyloid peptide (Aβ) is the main component of amyloid plaques, an established hallmark of AD, which are responsible in part for the progressive deterioration of cognitive and behavioral functions characteristic of the disease. Ample evidence exists suggesting that hyperglycemia and insulin resistance, two hallmarks of type 2 diabetes mellitus (DM2), are factors that contribute to accelerating the appearance of AD. In fact, insulin signaling appears to be involved in the modulation of Aβ production and degradation in transgenic mice models of AD. The mediobasal hypothalamus (MBH) has emerged as a neuronal center directly involved in the control of whole body insulin action, glucose homeostasis and energy balance. Although a number of in vivo neurotoxic actions of Aβ have been described, there is evidence to date of a no direct effect of Aβ on insulin action. Here we examined the hypothesis that Aβ exerts an acute neurotoxic effect in the MBH resulting in hepatic insulin resistance and impairment of glucose metabolism. We performed central (MBH) infusions of Aβ in normal young Sprague-Dawley male rats during basal pancreatic insulin clamps to assess whole insulin action and glucose kinetics by tracer dilution methodology. Our results indicate that during pancreatic clamps the acute infusion of Aβ but not scrambled peptide in the MBH decreased hepatic insulin sensitivity manifested by a failure of insulin to efficiently suppress hepatic glucose production (inhibition of basal glucose production 9.8 ± 2.7% for Aβ group vs. 28 ± 4.6% scrambled peptide; and net glucose production 11.2 ± 0.6 vs 9 ± 0.3 mg/kg/min, respectively). No changes in glucose disposal were observed. Changes in the phosphorylation of AKT, p70S6 kinase and S6 ribosomal protein were observed in both the MBH and livers of the treated animals. Importantly, the insulin-resistance induced by central Aβ occurred without changes in circulating insulin or glucose levels thus revealing a direct action of Aβ in the impairment of insulin action via the MBH. The ability of Aβ to acutely impair hepatic

glucose metabolism through its action in the hypothalamus is a previously unrecognized neurotoxic effect of Aβ.

Title: Knock-down of hypothalamic stearoyl-coa desaturase-2 reduces body mass of diet-induced obese mice

Authors: R. F. MOURA[1], L. F. R. NASCIMENTO[1], L. M. IGNÁCIO-SOUZA[1], G. F. P. SOUZA[1], J. MORARI[1], B. BOMBASSARO[1], *L. A. VELLOSO[2]
[1]Univ. of Campinas, Campinas, Brazil; [2]Campinas, Brazil

Abstract: Stearoyl-CoA desaturase is encoded by the scd gene, and is responsible for the conversion of saturated to monounsaturated fatty acids. The evaluation of SCD knockout mice unveiled a tissue-specific role for this gene in obesity. However, the specific role of hypothalamic SCD is yet to be addressed. Thus, the present study aims at investigating the role of hypothalamic SCD (SCD2) and its role in obesity. For that, five-week old Swiss male mice were fed on a high-fat diet during six weeks. After the four initial weeks, the animals were selected for its obesity predisposition phenotype as: obesity resistant (RS), or obesity prone (PR). Both groups were treated either with 4nmol SCD2 antisense (ASO) or vehicle (VE), once a day for two weeks. Body mass was evaluated once a week and spontaneous activity, O2 consumption and CO2 production were determined after ten days. The hypothalamus was extracted and the expressions of orexigenic/anorexigenic neurotransmitters were analyzed by real time PCR. After two weeks of ASO treatment, PRASO and RSASO groups had 11% and 5% reductions of body mass as compared to respective controls (p<0.05 for both groups). During the light period, ASO treatment promoted 38% decrease (p<0.05) in the RS groups activity, but no significant change in PR groups. However, during the dark period, ASO treatment promoted 25% and 44% increases of activity for RSASO and PRASO, respectively (p<0.05 for both groups). O2 consumption was not affected by the treatment, but CO2 production was 10% higher in either PRASO and RSASO groups as compared to controls. This change in CO2 production resulted in 11% and 13% increase in respiratory quotient for PRASO and RSASO, respectively, as

compared to controls. The orexigenic AGRP and the anorexigenics POMC and CART genes presented no differences regarding the treatment or phenotype. In conclusion, hypothalamic SCD2 plays a role on obesity, its inhibition promotes reduction of body mass mainly through increased nocturnal activity and increased CO2 production. Thus, SCD2 is a novel candidate target for the treatment of obesity.

Title: Estrogen is neuroprotective of hindbrain A2 noradrenergic metabolic sensory neurons during insulin-induced hypoglycemia.

Authors: *P. TAMRAKAR, B. A. IBRAHIM, K. P. BRISKI
Dept. of Basic Pharmaceut. Sci., Univ. Louisiana Monroe, Monroe, LA

Abstract: Energy deprivation due to insulin-induced hypoglycemia (IIH) poses a risk of CNS dysfunction and injury. Nerve cell metabolic status is monitored in select brain sites, including the hindbrain dorsal vagal complex, where the cellular energy sensor, adenosine 5'-monophosphate-activated protein kinase (AMPK), is localized to A2 noradrenergic neurons. Estrogen is reportedly neuroprotective against various bio-energetic insults, including stroke, but its actions on CNS neurons during IIH remain unclear. We utilized a novel combinatory approach, involving laser-catapult microdissection and high-sensitivity Western blotting, to examine premise that estradiol enhances A2 energy metabolism during IIH, thereby regulating A2 metabolo-sensory functionality. Quick-immunolabeled A2 cells were harvested 2 hr after neutral protamine Hagedorn insulin (INS) or vehicle (V) injection of ovariectomized female implanted with estradiol benzoate (E) or oil (O) for Western blot analysis of rate-limiting glycolytic, tricarboxylic acid cycle, and AMPK-malonyl CoA pathway enzymes. E enhanced basal A2 phosphofructokinase (PFKL) and isocitrate dehydrogenase (IDH2), but decreased acetyl Co-A carboxylase (ACC), calcium/ calmodulin kinase (CaMMKβ), and fatty acid synthase (FAS) expression. These enzyme profiles, as well as PP2A, were elevated, whereas phosphoAMPK levels were decreased in E vs. O A2 neurons during IIH. These data support the

view that estradiol improves nerve cell energy status during eu- and hypoglycemia through control of substrate fuel metabolism. Ongoing studies seek to determine if estrogenic regulation of pAMPK is achieved by effects on ATP production and/or direct control of upstream kinase and phosphorylase activity. The current research extends current knowledge of neurochemical, hormonal, and nutrient stimuli that govern CNS AMPK function to include estrogen. The results also establish a platform for investigation of estrogenic control of neuronal fatty acid biosynthesis during energy balance versus deficiency.

Title: Rapid, area-specific fluctuations in extracellular brain glucose levels induced by natural arousing stimuli and intravenous cocaine in freely moving rats: Critical role of neural activity.

Authors: *E. A. KIYATKIN, M. LENOIR
Behavioral Neurosci Br., NIDA-IRP, NIH, DHHS, BALTIMORE, MD

Abstract: Glucose, a primary energetic substrate for neural activity, is continuously influenced by two opposite forces, which tend to either decrease its extracellular levels due to enhanced utilization or increase its levels due to entry from peripheral circulation via enhanced cerebral blood flow. In this study, enzyme-based glucose sensors coupled with high-speed amperometry were used in freely moving rats to evaluate rapid fluctuations in extracellular levels of glucose induced by a brief audio stimulus, tail-pinch (TP), social interaction with another rat (SI), and intravenous cocaine (1 mg/kg). Our measurements were conducted in two basal ganglia structures, nucleus accumbens shell (NAcc) and substantia nigra pars reticulata (SNr), which drastically differ in neuronal activity and responsiveness to afferent challenges. In the NAcc, where most cells are silent or sporadically active and show powerful excitations following salient stimulation, all stimuli induced a rapid (latency 2-6 s) increase (30-100 microM or 6-20% over baseline) in glucose levels; the increase differed in its magnitude and duration for each stimulus. In the SNr, where most cells have high rates of basal impulse activity and show transient inhibitions following salient stimulation, TP, SI and cocaine transiently decreased glucose levels (-20-40 microM or 5-10% below baseline); the decrease has longer latencies (~40 s) and

followed by a rebound-like glucose increase. To confirm the role of neuronal activity in mediating the initial glucose response, electrochemical currents were monitored following local microinjections of either glutamate (GLU) or procaine (PRO). While intra-NAcc injection of GLU transiently increased glucose levels in this structure, intra-SNr PRO injection resulted in rapid, transient decreases in SNr glucose levels. Therefore, extracellular glucose levels in the brain could change very rapidly following physiological stimulation, the response is structure-specific, and the pattern of neuronal activity appears to be a critical factor affecting the direction and magnitude of physiological fluctuations in extracellular glucose levels.

Title: Comparative study of the chronic effect of chorogenic, caffeic acid, and caffeine on glucemy, triglyceridemia, cholesterolemia, and, glucose and Insulin resistance in healty and diabetic rats

Authors: *M. HUERTA-VIERA, Z. URZÚA, C. RAMOS-FLORES, X. TRUJILLO
Ctr. Univ. Inv Biomed (CUIB), Univ. De Colima, CUIB, Colima, Mexico

Abstract: Previous studies indicate that the long-term consumption of roasted coffee regularly (with Caffeine, Chlorogenic and Caffeic acid), and decaffeinated coffee (without caffeine) reduces the risk of diabetes mellitus type 2 (DM2) in people taking both types of coffee (Van Dam and Hu, 2005; Van Dam et al, 2006). To determine whether chronic administration of Caffeine, Chlorogenic acid, and Caffeic acid decreases the levels of Glucose, Triglycerides and blood cholesterol and improve Glucose tolerance in rats with experimental diabetes. Using 5 groups of 11 male Wistar rats weighing 250-350 g type 2 diabetes was generated by high-fat diet for 60 days and then applied three doses of Streptozotocin (30 mg/Kg IP) administered on day 60, 67 and 74. One group was the control and other groups were given Caffeine (93 mg/Kg/day), Chlorogenic acid (31 mg/Kg/day), and Caffeic acid (1 mg/Kg/day), other group, were administered with the three substances together, respectively; for 4 months. Each month were tested for Insulin tolerance (IT) and Glucose tolerance (GT). These were also measured every 72

h blood Glucose, Triglycerides (TG) and Cholesterol, every 7 days for 4 months. Statistical analysis was performed with repeated measurements ANOVA Post Hoc test like Scheffe, when the distribution was normal, otherwise the test was with the Kruskal Wallis by using SPSS v15. We found significant differences in the group with Caffeine in Cholesterol, Triglycerides and in the weight. In the group with Chlorogenic acid alone, there was difference in the variable TG. For the group with the administration of the three substances together, significant differences were found in Cholesterol, Triglycerides, and in weight. Similarly with fasting glucose, GT difference remained significant in this group. However, Caffeic acid does not alter the study variables. Finally, our Results suggest that Caffeine reduces the levels of Cholesterol, Triglycerides and weight; Chlorogenic acid decreases the TG levels; Caffeic acid has no effect on the studied variables, but the three substances were together administrated significative differences were found in Cholesterol, TG, weight, fasting glucose and GT. Partially financed by CONACyT-Mexico 83113 to MH. ZUG, and CRF are CONACyT fellowships.

Title: Stimulation of dorsomedial hypothalamic leptin receptor (LepRb)-expressing neurons induces thermogenesis and energy expenditure in LepRbcre mice.

Authors: *K. P. REZAI-ZADEH, A. LAQUE, K. BUI, T.-A. NGYEN, S. GETTYS, C. MORRISON, H. MUNZBERG
Pennington Biomed. Res. Ctr., Baton Rouge, LA

Abstract: Obesity is a significant problem in the U.S. and current non-invasive treatments like dieting and physical exercise remain largely ineffective. Modification of energy expenditure via the induction of non-shivering thermogenesis (NST) in brown adipose tissue (BAT) is currently

reemerging as a potential obesity therapy. The dorsomedial hypothalamus (DMH) is thought to be a key site for the regulation of BAT NST. We recently showed that DMH neurons express leptin receptors (LepRb) and innervate premotor neurons that control BAT thermogenesis. Here, we show that systemic leptin administration also stimulates neuronal activity in DMH LepRb-expressing neurons, suggesting that neuronal activity in these cells may directly translate into increased energy expenditure. Furthermore, we found that intra-DMH leptin injection corrects hypothermia in leptin deficient *ob/ob* mice and causes significant weight loss, despite having no impact on food intake. We further examined if stimulation of neuronal activity in DMH LepRb-expressing neurons regulates energy expenditure and body weight in mice. By injecting a viral vector [AAV-hSyn-DIO-hM3D(G_q)-mCherry – made available by Dr. Bryan Roth, UNC] into the DMH of $LepRb^{cre}$ mice we were able to express cre-inducible designer receptors exclusively activated by designer drugs (DREADD) and thereby pharmacologically control the activity of DMH LepRb neurons. After implantation of subcutaneous temperature transmitters and recovery, animals were adapted to metabolic chambers and injected with saline or the designer drug clozapine-N-oxide (CNO) for 3 days each (twice daily). CNO caused a robust increase in energy expenditure accompanied by a significant decrease in body weight in CNO-responsive mice (CNO-induced energy expenditure) compared to CNO non-responders (no change in energy expenditure). Histological analysis revealed that CNO-responders showed DREADD expression in the DMH, while non-responders did not. Altogether, our data demonstrate that induction of neuronal activity in DMH LepRb-expressing neurons translates into increased energy expenditure leading to decreased body weight.

Title: Ablation of Glutamate Dehydrogenase expression in cultured mouse astrocytes alters both oxidative glutamate and glucose metabolism

Authors: *M. H. STRIDH[1], D. M. SKYTT[1], K. PAJECKA[1], M. KARACA[2], F. FRIGERIO[2], P. MAECHLER[2], A. SCHOUSBOE[1], H. S. WAAGEPETERSEN[1]

[1]Dept. Of Drug Design and Pharmacol., Univ. of Copenhagen, Copenhagen, Denmark; [2]Dept. of Cell Physiol. and Metabolism, Geneva Univ. Med. Ctr., Geneva, Switzerland

Abstract: As an integral part of the tri-partite synapse, the astrocytes provide optimal conditions for neuronal function and signalling. Astrocytes are equipped with high affinity transporters to ensure an efficient clearance of glutamate from the synapses and they ensure transmitter recycling via the glutamate/glutamine cycle. However, glutamate is also a valuable energy substrate and astrocytes are capable of fully oxidizing glutamate in the TCA-cycle. The mitochondrial enzyme glutamate dehydrogenase (GDH) catalyzes the oxidative deamination of glutamate to α-ketoglutarate and may therefore play an interesting role in linking glutamate homeostasis to energy metabolism. To evaluate the role of GDH in astrocyte energy metabolism, cultured astrocytes were prepared from CNS-*Glud1*$^{-/-}$ mice. Energy and glutamate metabolism were investigated in cultured astrocytes using [U-^{14}C]glutamate or [U-^{14}C]glucose and monitoring of $^{14}CO_2$ production. The metabolism was further mapped by incubating astrocytes with [U-^{13}C]glucose or [U-^{13}C]glutamate followed by analysis of labeling in amino acids and TCA-cycle metabolites using mass spectrometry.
Incubation with [U-^{13}C]glucose generated an significant increase in uniformly labeled alanine in *Glud1*$^{-/-}$ astrocytes compared to wt. Since alanine is in equilibrium with pyruvate, this indicates increased glycolysis in *Glud1*$^{-/-}$ astrocytes. In contrast to the augmentation in glycolytic activity, the CO_2 production from [U-^{14}C]glucose was decreased in astrocytes from *Glud1*$^{-/-}$ mice indicating an impaired TCA-cycle activity. The ability to use glutamate as an alternative energy substrate is clearly compromised in *Glud1*$^{-/-}$ astrocytes. Upon glucose deprivation, wt astrocytes are able to increase the $^{14}CO_2$ production from [U-^{14}C]glutamate, whereas this increase is absent in *Glud1*$^{-/-}$ astrocytes. Online monitoring of ATP production revealed that *Glud1*$^{-/-}$ astrocytes were unable to respond with increased ATP production upon stimulation with 1mM glutamate, in contrast to WT cells. It was also evident from these results that the *Glud1*$^{-/-}$ astrocytes had a lower baseline level of ATP indicating that they might be energetically challenged by the short period of glucose deprivation preceeding the ATP measurements. This finding further supports the notion that lack of GDH function alters glucose metabolism.
In conclusion, ablation of GDH expression in astrocytes causes the astrocytes to shift toward a more glycolytic metabolism

and there is evidence of an impaired TCA cycle function. The capability of astrocytes to use glutamate oxidation as an alternative energy source during glucose deprivation is dependent on GDH function.

Title: Synphilin-1 regulates ampk and atp

Authors: *D. YANG[1], T. LI[2], J. LIU[2], X. LI[3], G. ZHU[4], T. MORAN[5], W. SMITH[2]
[1]Dept. of Pharmaceut. Sci. Univ. of Maryland Sch. of Pharm., Baltimore, MD; [2]Pharmaceut. Sci., [3]Univ. of Maryland Sch. of Pharm., Baltimore, MD; [4]Johns Hopkins Univ. Sch. of Med., Psychiatry, MD; [5]Psychiatry, Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: We recently generated a human synphilin-1 transgenic mouse model that displays some key features of obesity including increased food intake, body weight and body fat. Synphilin-1 is a cytoplasmic protein enriched in brain with unclear function. To further study the roles of synphilin-1 in energy balance control, we generated a stable pool of GT1-7 cells expressing human synphilin-1. We found that synphilin-1 increased AMP-activated kinase (AMPK, a cellular energy sensor) phosphorylation. Moreover, synphilin-1 interacted with AMPK in cultured cells and in homogenates of human brain tissues. Treatment of compound C, an AMPK inhibitor reduced synphilin-1 interacted with AMPK. Synphilin-1 also bound with the major energy currency, adenosine triphosphate (ATP) and increased cellular ATP levels. The two ATP binding regions and five motifs in synphilin-1 were mapped with truncated constructs and site mutagenesis. Genetic alterations abolishing ATP binding sites significantly reduced synphilin-1-induced AMPK activation and normalized cellular ATP levels. These data suggest that synphlin-1 is an ATP binding protein and regulates AMPK activity via ATP binding. These studies may provide novel insights into synphilin-1's biological functions and potential mechanism for affecting energy balance.

Title: An energy budget for the recovery of spreading depolarisation - Multimodal measurement and kinetic modelling.

Authors: D. FEUERSTEIN[1], H. BACKES[1], M. GRAMER[1], M. TAKAGAKI[1], *A. J. STRONG[2,1], R. GRAF[1]
[1]Max Planck Inst. for neurological research, Cologne, Germany; [2]Clin. Neurosci., Kings Col. London, London, United Kingdom

Abstract: Spreading depolarisation (SD) is a slowly propagating wave of tissue depolarisation that could be closely linked to secondary deterioration of brain injury patients. It is hypothesised that progressive worsening of the lesion would be due to the hemodynamic and metabolic disturbances caused by the SDs. We have here investigated these events by simultaneously measuring:
• cerebral blood flow with laser speckle flowmetry (LSF)
• oxygen consumption with multispectral reflectometry (RGBR)
• glucose utilization with FDG-PET
• glucose and lactate concentrations in the extracellular space with online microdialysis (rsMD)
These data were then integrated into a kinetic model of brain metabolism that accounted for the rates of glucose transport, glycolysis, mitochondrial oxidative metabolism, lactate production and use, glycogen breakdown and synthesis.
Methods: LSF and RGBR were continuously acquired in male Wistar rats through thinned skull. A microdialysis probe was implanted via a small craniotomy and the dialysate was analysed for glucose and lactate concentrations every minute by rsMD. After recovery from implantation and baseline measurement, FDG was injected. At 20 minutes post-injection, SDs were elicited either by needle prick (single SD) or KCl infusion (multiple SDs). The hemodynamic and metabolic responses to SDs were observed for 70 minutes.
Results: SD waves were detected by LSF as propagating hyperemic waves. The response to one

single SD wave was biphasic: 1) within 5 minutes, glucose dropped by 20%, lactate increased by 60%, oxygen consumption increased by 20% and FDG uptake rose above control, 2) during the next 65 minutes, glucose and oxygen consumption remained below baseline, lactate fully recovered and FDG uptake gradually declined to normal values. This response could be modelled by a transient surge for ATP followed by a prolonged reduced energy demand. During phase 1, glycogen is rapidly broken down and glucose is fully catabolised via glycolysis and mitochondrial oxidative metabolism. During phase 2, cells are repolarised and glycogen stores are re-filled.
Following multiple SD waves, we observed a sustained increase in energy demand, with an ever-decreasing extracellular glucose, a prolonged elevated lactate level, and an up to 40% increase in FDG uptake. This indicates a prolonged period of high energy demand that might lead to irreversible damage.
Conclusion: We suggest that the energy requirements to recover from a single SD wave are largely fulfilled in physiological conditions. However frequent SDs could lead to an energy crisis that endangers tissue viability even in a well-perfused brain.

Title: Variation in cerebral glucose transporter expression across the estrous cycle

Authors: *C. S. HARRELL[1], S. MALVIYA[1], S. D. KELLY[1], G. N. NEIGH[2]
[2]Physiol. and Psychiatry, [1]Emory Univ., Atlanta, GA

Abstract: Glucose is the primary fuel of the brain and alterations in glucose availability directly impact neuronal function. Cerebral glucose metabolism is disrupted in several neuropsychiatric and neurodegenerative disorders, and can further be affected by peripheral disturbances of glucose metabolism such as diabetes. Variation in glucose transport is influenced by hormonal state, yet models of cerebral glucose transport focus on the male and ovariectomized female and fail to explore how physiological fluctuations in sex steroids influence glucose transporters and insulin signaling. Female sex steroids impact glucose metabolism in contrasting ways; estradiol enhances glucose uptake and insulin sensitivity, while progesterone decreases glucose uptake

and promotes insulin resistance. Cerebral glucose uptake varies during the estrous cycle, with uptake highest during proestrus in the rat, when estradiol levels peak. Cerebral glucose uptake is mediated by a family of facilitative glucose transporters (GLUTs) that show isoform-specific distribution and regulation. We examined four members of this family: GLUT1, GLUT3, GLUT4, and GLUT8. GLUT1 primarily regulates blood-brain barrier glucose transport while GLUT3 is responsible for the majority of glucose uptake into neurons. GLUT4 and GLUT8 are both insulin-sensitive transporters; insulin receptor activation results in GLUT4 translocation to the plasma membrane and GLUT8 translocation to the endoplasmic reticulum. Our studies demonstrate that natural variation in sex steroids across the estrous cycle co-occur with changes in glucose transporter expression. Estrous cycles in adult female rats were monitored daily, and tissue was collected based on cycle stage. Uterine weights and serum estradiol and progesterone were used to further confirm cytologic staging. The hippocampus, hypothalamus, and prefrontal cortex were dissected for examination of glucose transporter expression. Our experiments demonstrated that each GLUT examined peaked in proestrus and with lowest expression in diestrus 1 (D1). Further, GLUT1 also showed significant elevations between D1 and diestrus 2 (D2), suggesting that this transporter may be most responsive to the rise in estradiol beginning in D2. These studies confirm the importance of hormonal state in regulating cerebral glucose transport, and provide an important baseline for further work on cerebral glucose metabolism in the female.

Title: Activation of TRPV1 in the paraventricular nucleus of hypothalamus regulates systemic blood glucose levels

Authors: *K. MIYATA, J. O'HARE, T. FOURRIER, A. KRANTZ, A. DERBENEV, A. ZSOMBOK
Tulane Univ., New Orleans, LA

Abstract: The autonomic nervous system plays a pivotal role in the regulation of glucose homeostasis. Transient receptor potential vanilloid type 1 (TRPV1) receptors colocalize with liver-related neurons in the paraventricular nucleus (PVN) of hypothalamus. Furthermore, our previous study demonstrated TRPV1-dependent excitation of liver-related PVN neurons. However, the effect of TRPV1 activation on whole body glucose homeostasis remains to be elucidated. The aim of this study was to demonstrate whether TRPV1 activation in the PVN mediates whole body glucose homeostasis. We examined systemic blood glucose levels, serum insulin levels, expression of hepatic gluconeogenic enzymes and Akt phosphorylation in male CD1 mice. Activation of TRPV1 by injecting capsaicin (0.5 nmol) bilaterally into the PVN significantly decreased systemic blood glucose levels. The reduction was detectable up to 30 min, with a maximum approximately at 15 min. The glucose lowering effect of TRPV1 was suppressed in the presence of the glutamate receptor antagonist, kynurenic acid. Serum insulin levels detected with ELISA did not show significant difference between groups. Moreover, activation of TRPV1 in the PVN decreased hepatic PEPCK levels, while there was no difference in G6Pase, and Akt phosphorylation levels. Our results demonstrate that systemic blood glucose levels are controlled by activation of TRPV1 in the PVN. Supported by AHA 10GRNT4540000, Tulane BIRCWH 2K12HD043451.

Title: Treadmill exercise rapidly induces the expression of hif-1α in the hippocampus of the adult rat

Authors: *K. L. BERGGREN, B. S. AHUJA, J. J. M. KAY, B. POCHINSKI, R. A. SWAIN
Psychology, Univ. of Wisconsin - Milwaukee, Milwaukee, WI

Abstract: Exercise induces a myriad of effects on the brain from the growth of new blood vessels (angiogenesis) and neurons (neurogenesis), to improvements in cognitive performance. A very recent study has found that in addition to angiogenesis and neurogenesis, commencement of an exercise regimen also causes cell death. This apoptosis also occurs shortly after the start of exercise, with levels of caspase-3 increasing at 12 hours and peaking within 24 hours of

voluntarily exercising. It is possible that exercise-induced increases in oxygen demand cause the brain to transiently experience a mild state of hypoxia causing cells to die. To investigate this hypothesis, we exposed male Long Evans rats to a six-day handling and pre-exposure procedure followed by a single bout of moderately intense treadmill exercise (20 minutes at ~15 meters/minute). Following the exercise session, animals were sacrificed and transcardially perfused at one of four time points: immediately (EX0), two hours (EX2), four hours (EX4), or six hours (EX6) after exercise. Additional groups of animals (inactive controls – IC0, IC2, IC4, & IC6) that did not exercise followed the same handling and pre-exposure procedures and were sacrificed at the same time points as the exercising animals. To determine if exercise induces hypoxia in the hippocampus, we measured via immunohistochemistry, protein levels of the hypoxia-inducible factor 1-alpha (HIF-1α), a transcription factor known to be upregulated in the brain under conditions of low oxygenation such as during and after ischemia, or exposure to an hypoxic environment. Following immunohistochemistry, tissue slices were imaged and analyzed using Image J software to determine the area fraction of HIF-1α-positive cells in the whole hippocampus as well as in three distinct hippocampal regions: CA1, CA2/3, and the dentate gyrus (DG). Preliminary data show that animals that were sacrificed immediately following exercise had significantly greater HIF-1α expression in the whole hippocampus compared to inactive animals. Furthermore, results indicate that EX0 animals showed greater HIF-1α expression in area CA1 of the hippocampus. These findings indicate that a single bout of moderately strenuous exercise induces hypoxia in the hippocampus. Furthermore, because HIF-1α is a common molecule of interest in stroke and hypoxia research, exercise may be considered another method with which to study the molecular pathways involved in alterations of brain oxygenation, and the mechanisms activated in an attempt to return the brain to normal oxygen homeostasis.

Title: Neuroprotective effect of flavonoids in hypobaric hypoxia in murine model

Authors: *A. SARKAR, S. M. ANGELINE, K. ANAND, P. ASTHANA, P. CHATTERJEE, R. K. AMBASTA, P. KUMAR
VIT Univ., Vellore, India

Abstract: Exposure to high-altitude results in hypobaric hypoxia which is considered as an acute physiological stress. This condition often leads to high-altitude illnesses such as high-altitude cerebral edema (HACE), high altitude pulmonary edema (HAPE) and hypoxic muscle weakness. One way to prevent hypoxic injuries is preconditioning with cobalt chloride, and another is treatment with effective drugs. Herein, we evaluated the effect of naringenin and quercetin against behavioral impairment and neuronal damage in hypoxia induced murine model. Hypoxia models were generated using *Swiss albino* mice. Oral dosage of quercetin and naringenin was administrated before every hypoxia treatment. Drug treated groups exhibited improved histopathological morphology validated by amino-cupric silver staining. We further checked the expression level of HIF1α, caspase-3 and ubiquitin. Drug treated brain showed decline in HIF1α level. Decreased expression of caspase 3 and ubiquitin in treated brain suggests the neuro protective effect of naringenin and quercetin in hypoxia induced damages.

Abstract: Large number of people (especially army or rock climber) travel to high altitudes, entering an environment of hypobaric hypoxia. It has been known that high-altitude exposure is an aggressive physiological stress that induces several cellular deleterious effects. Previous findings have shown that high-altitude hypoxia triggers increased oxidative stress which is a

favourable condition for the activation of apoptotic cellular death pathways. In response to this hypobaric hypoxia several systemic and peripheral physiological responses are acutely and chronically triggered out to counteract the body overall hypoxic status. Hypoxic injuries can be prevented by either preconditioning or treatment with drugs. In the present study, the effect of naringenin against behavioural impairment and muscle damage in the *in vivo* acute and chronic hypobaric hypoxic mice model has been investigated. Male mice were randomly divided into the five groups and drug was administrated orally. In contrast with a regular skeletal muscle pattern observed in normoxia group, acute and chronic hypoxic group revealed profound structural alterations in the skeletal muscle tissue organization. Whereas treatment with naringenin substantially improved hypoxia induced skeletal muscle dysfunction confirmed by hematoxylin and eosin staining and behavioral test. Further, the protective nature was corroborated with immunoblot and immunoflurescence results where we confirmed the modulation of HIF1α and apoptotic markers. To conclude, the results suggest that naringenin prevents the loss of skeletal muscle integrity and function, against acute and severe hypobaric hypoxia.

Title: Thyroid hormone increases astrocyte survival in response to oxidative stress

Authors: N. L. SAYRE, D. HOLSTEIN, *J. D. LECHLEITER
Cell. & Structural Biol., Univ. of Texas Hlth. Sci. Ctr. At San Antonio, SAN ANTONIO, TX

Abstract: In tissue surrounding ischemic stroke, disrupted energy metabolism leads to inability to maintain ionic gradients, in turn causing swelling and rupture of cells. Astrocyte metabolism represents a particularly attractive therapeutic target during stroke because astrocytes play numerous supportive roles and can significantly influence neuronal health. Indeed, our laboratory has previously demonstrated that enhancing astrocyte mitochondrial metabolism is neuroprotective in stroke[1] and in aging[2]. Similarly, our laboratory has shown that mitochondrial energy production can be increased via thyroid hormone receptor (TR) activation by treatment with the thyroid hormone 3,3'5 triiodo-L-thyronine (T3) [3].

The effect of thyroid hormones on energy metabolism is traditionally attributed to changes in gene expression, however we discovered a novel, non-genomic function of T3. Specifically, T3 treatment stabilizes the association of subunits within mitochondrial trifunctional protein in a TR dependent manner, which in turn increases fatty acid oxidation (FAO) and energy production. We previously showed that acute treatment with T3 increases FAO in fibroblasts[4]. Astrocytes are also capable of FAO. **We hypothesize that T3 increases astrocyte FAO and energy production, therefore increasing astrocyte survival after oxidative stress.**
Here we describe the effect of T3 treatment on astrocyte survival and fatty acid oxidation. Importantly, astrocyte survival after *tert*-butyl hydrogen peroxide treatment significantly increased with nanomolar concentrations of T3. Similarly, fatty axid oxidation of palmitate also increases. Future directions include determining whether the T3-mediated survival of astrocytes after oxidative damage is dependent on the increased fatty acid oxidation, and whether T3 mediates survival after stroke *in vivo.*

Title: Frequency of autonomous electrical activity is modulated by extracellular glucose concentration in a cultured neuronal network.

Authors: *W. MINOSHIMA, S. N. KUDOH, H. ITOH
Japan/Graduate Sch. of Sci. and Tech., Kwansei Gakuin Univ., Sanda/Hyogo, Japan

Abstract: Cultured rat hippocampal neurons on a multi electrode array (MEA) dish are useful system for analyzing network electrical dynamics and its developmental changes. Neurons autonomously form a complex network on a MEA dish and spontaneous electrical activity is often observed without any input from the external world. The spontaneous activity is generated by synaptic interactions between neurons and reflects internal biochemical state of neurons in a whole neuronal network. The origin of electrical activity is electrochemical potential generated by active transport of ions, which requires catabolism of ATP. We elucidated relationship between autonomous electrical activity and external glucose concentration. The spatiotemporal pattern of autonomous activity changed transiently, depending on glucose concentrations, and we analyzed the number of spikes in autonomous activity. Electrical spikes increases in frequency depending on the concentration of external glucose. Interestingly, this increase is not suppressed but turn to decrease. In the case of glucose concentration is 17.5 mM, the number of activity is the most, and then it decreases in the case of glucose concentration is more than 17.5 mM. In addition, the decrease of neuronal activity at high glucose concentration is not influenced by the blockade of inhibitory synaptic activity, suggesting the decrease is intrinsic in activity generating process. A cultured neuronal network may have an optimal glucose concentration, which corresponds to the concentration of glucose in a culture medium (17.5 mM).

Title: Molecular mechanisms of natural neuroprotection in a hibernating mammal.

Authors: *C. P. SCHWARTZ[1], M. HAMPTON[2], M. T. ANDREWS[1]
[1]Biol., [2]Mathematics, Univ. of Minnesota Duluth, Duluth, MN

Abstract: During hibernation, thirteen-lined ground squirrels undergo rapid and extreme changes in body temperature and brain perfusion as they cycle between lengthy torpor bouts (7-10 days) and brief periods of euthermia called interbout arousals (IBAs, <24 hours). Arousal from torpor to IBA, where body temperature increases from 5 to 37ºC and heart rate explodes from 3 to 300-400 beats/min, takes just 2-3 hours. Amazingly, the hibernator brain tolerates these rapid fluctuations with no residual damage, suggesting a sophisticated neuroprotective strategy, along with a robust central control system to coordinate the changes. Adding even more complexity, different areas of the brain show very different activity profiles during hibernation. The hypothalamus remains active throughout the season, even in deep torpor, and is thought to play an important role in the induction and maintenance of hibernation. In contrast, the cerebral cortex is the first area of the brain to lose activity upon entrance to torpor, and the last to regain activity upon arousal. Examining the molecular changes occurring in these two differentially regulated areas of the ground squirrel brain during hibernation could provide valuable insight into how hibernation is centrally controlled, and also reveal neuroprotective mechanisms that allow variable brain activity. To do this, we used the Illumina HiSeq 2000 system to sequence the transcriptome of the hypothalamus and cortex at four time points during the hibernation season: October, Torpor, IBA, and April. Over 10 million raw cDNA sequence reads per sample were identified and quantified using species-specific contigs and an analysis of deviance was performed for each gene to determine differential expression across time points. Of 15,318 genes identified in the hypothalamic transcriptome, 1,554 showed differential expression ($p<0.01$). In the cortex, 15,184 genes were identified and 977 were differentially expressed ($p<0.01$). An overrepresentation analysis revealed that transcripts associated with neuron morphogenesis, plasticity, and ion homeostasis were significantly upregulated during torpor in the cortex. In the hypothalamus, transcripts involved in basic cell functions (transcription, translation, cellular respiration), along with DNA repair and neurogenesis were significantly upregulated in both torpor and IBA. The data from this transcriptomic study has revealed many genes and pathways underlying the physiological changes associated with hibernation and mechanisms of protection promoting survival in the brain during these rapid and extreme physiological changes.

Title: Behavioral and physiological changes in naked mole-rats in environmental hypoxia/hypercapnia.

Authors: *D. P. MCCLOSKEY[1], X. GEOFFROY[2], S. ABRAHAM[3], R. ASSINI[3], I. RABINOVICH[4]

Abstract: The naked mole-rat (Heterocephalus Glaber) is a eusocial, exclusively subterranean, species of rodent that lives in extensive burrow systems in eastern Africa, with colonies as large as 300 animals. This ecological niche can present a hypoxic/hypercapnic environment which field studies suggest these animals can tolerate very well, and previous in vitro work shows the adaptation is present at the neuronal level. The purpose of this study was to measure the impact of a reduced O2 (18.5%), elevated CO2 (3.5%) environment on behavioral and physiological measures in laboratory housed naked mole-rats to further understand this adaptation. A colony of 22 animals was measured under normal conditions, followed by 96 hours of hypercapnic/hypoxia. Animal movements were tracked in a complex housing system using a custom radio frequency identification (RFID) equipment. Common tunnel paths between interconnected cages in the housing environment were periodically closed to measure learning effects in adapting to altered environments. Brain levels of growth factors (VEGF, BDNF) and hormones (cortisol) were measured in a subset of animals. Our results suggest that animals in the hypoxic/hypercapnic environment move slower, but are more social, more active, and less disrupted by closing of tunnels. Video recordings showed robust seizure-like behavior in multiple animals as normoxia was being restored to the environment. Follow up studies suggest that these animals are prone to seizure activity in normoxia, which we have confirmed in hippocampal slice electrophysiology recordings. Together, these data suggest that the naked mole rats are sensitive to gaseous changes in the local environment, but in different ways than other mammals.

Title: Hypoxia alters metabolic rate, core body temperature and c-fos expression in the naked mole rat

Authors: *T. I. NATHANIEL[1], E. OTUKONYONG[2], J. SOYINKA[3]
[1]Biomed. Sci., Univ. of South Carolina Sch. of Med. At Greenville, Greenville, SC; [2]Dept. of Hlth. Sci., East Tennessee State Univ., Johnson City, TN 37614., TN; [3]Dept. of Pharmaceut. Chemistry,, Obafemi Awolowo Univ., IleIfe, Nigeria

Abstract: Recent investigations of hypoxia physiology in the naked mole rat have opened up an interesting line of research into the basic physiological and genomic alterations that accompany hypoxia survival. The extent to which such findings connect the effect of hypoxia to metabolic rate (O2 consumption), core body temperature (Tb) and transcripts encoding the immediate early gene product (such as c-fos) under a constant ambient temperature (Ta) is not well known. We investigated this issue in the current study. Our first sets of experiments measured Tb and metabolic rates during exposure of naked mole rats to hypoxia over a constant Ta. Hypoxia significantly decreased metabolic rates in the naked mole rat. Although core Tb also decreased during hypoxia, the effect of hypoxia in suppressing core Tb was not significant. The second series of experiments revealed that c-fos protein expression in the hippocampus neurons (CA1) increased in naked mole rats that were repeatedly exposed to 3% O2 for 60 min each day for 5 days when compared to normoxia condition. Our findings provide evidence for the up-regulation of c-fos protein, suppression of Tb, and metabolic rate in hypoxia tolerating naked mole rats under constant ambient temperature.

Title: Spontaneity in the task-incidental segments of the pointing gesture emerges when visual guidance or movement imagination replace proprioception

Authors: *E. B. TORRES[1], J. COLE[2], H. POIZNER[3]
[1]Psychology Dept, Rutgers Univ., Piscataway, NJ; [2]Ctr. for Neurosci., Univ. of Southampton, Poole, United Kingdom; [3]Inst. for Neural Computation, UCSD, La Jolla, CA

Abstract: Patient IW lost his proprioception at the age of 19 due to a large fiber sensory neuropathy that led to the loss of the sensation of movement/position sense and light touch, below the neck (Cole, 1995). He eventually taught himself how to move using mental concentration and visual supervision; later he used mental rehearsal and imagery to prepare and launch movements. He developed fluid, spontaneous gestures that masked his lack of kinesthetic feedback rather well and made his motions look effortlessly natural. It seems puzzling that voluntary visual guidance resulted in such fluid spontaneous motions. However, both visual supervision and the mental processes involved in imagining and deciding over proper muscle configurations to attain a movement have two co-existing modes: slow-deliberate-conscious and fast-spontaneous-unconscious. Therefore, it would not be entirely surprising that his gestures eventually evolved in correspondence with other mental operations that came to replace his loss of kinesthetic sensation. Here we asked if the deliberate-spontaneous dichotomy would also manifest in the kinematics of the pointing movements of IW as it typically does in normal Controls (NC). To this end, participants made full pointing motions in a continuous forward and back loop with a deliberate, task-relevant segment intended to touch a target in space and a retracting task-incidental segment spontaneously transitioning to bring the hand back to rest. The target in some blocks was turned OFF and had to be memorized, while in others it remained ON and guided the motion throughout. In other blocks, we instructed subjects to move at different speeds to probe the effects of speed change on the hand trajectories -since the stochastic signatures of speed modulation and its effects on the hand trajectories can be used as an objective criterion to separate deliberate task-relevant from spontaneous task-incidental gestures (Torres, 2011). We found that the kinematics of his visually guided reaches in a fully lit room manifested the signatures of variability leading to the deliberate-incidental dichotomy that we also quantified in the NC. Remarkably, these features were quantified even in the dark (albeit more variable), suggesting that the fluidity of his retracting motions spontaneously emerged despite his voluntary control. Thus, both visual supervision and the imagination of movements integrated with his

efferent motor output can indeed lead to the two-movement class dichotomy, slow-deliberate and fast-spontaneous, a dichotomy that is also present in our cognitive mental processes.

Title: Motor cortical plasticity is enhanced by passive observation of mirror-matched limb movements.

Authors: *M. V. SALE[1], J. B. MATTINGLEY[2]
[1]Univ. of Queensland, St Lucia, Australia; [2]Queensland Brain Inst., Univ. of Queensland, Brisbane, Australia

Abstract: Watching others learn a motor task can enhance an observer's own later performance when learning the same motor task. This is thought to be due to activation of the action observation (or mirror neuron) network. Here we show that the effectiveness of plasticity induced in human motor cortex (M1) is significantly influenced by the nature of prior action observation. In separate sessions, 17 participants watched a video showing repeated goal-directed movements (action
observation) involving either the right hand (congruent condition) or the same video mirror-reversed to simulate the left hand (incongruent condition). Participants then repeatedly performed the movements observed in the congruent video, while receiving pulses of transcranial magnetic stimulation over the hand area of M1 paired with median nerve stimulation of the right hand (paired associative stimulation; PAS). The resting motor-evoked potential (MEP) in right abductor pollicis
brevis (APB) increased significantly 20 minutes after PAS, but only when participants had previously watched the congruent video. In this condition, all participants showed an increase in

MEP amplitude at 20 minutes post-PAS. There was no change in MEP amplitude following PAS when participants watched the incongruent video. We conclude that prior action observation is a potent modulator of subsequent PAS-induced neuroplasticity, which may have important therapeutic applications.

Title: Delayed visual feedback does not prevent updating of an internal model, but slows error reduction in PD patients

Authors: *L.-A. LEOW[1], A. M. LOFTUS[2], G. HAMMOND[1]
[1]Sch. of Psychology, Univ. of Western Australia, Perth, Australia; [2]Facultry of Hlth. Sci., Sch. of Psychology & Speech Pathology, Curtin Univ., Perth, Australia

Abstract: It has been argued that simultaneous presentation of visual feedback during visuomotor adaptation is necessary to update an internal model, as delaying presentation of visual feedback resulted in small aftereffects, lengthened reaction time and large trial-to-trial variability in directional error, which suggests error reduction through compensatory strategies (Shabbott and Sainburg 2010; Hinder et al. 2010; Hinder et al. 2008). Delayed visual feedback is a demanding adaptation condition: increasing delays systematically slows the rate of error reduction (Kitazawa et al. 1995). Previous findings may be due to a combination of multiple demanding adaptation conditions (delayed feedback, large perturbation and multiple targets) which provoke the use of compensatory strategies to reduce error. It is hypothesized that delayed visual feedback combined with less demanding adaptation conditions allows error reduction by updating an internal model, evident through large aftereffects which decay trial-by-trial. As Parkinson's Disease (PD) patients are more reliant on visual feedback for movement, it is hypothesized that adaptation performance in PD patients may be more sensitive to delayed visual feedback. Method: Less demanding adaptation conditions (30° rotation, a single target) were used throughout this study. Participants (PD patients and neurologically intact young and older adults) completed 50 adaptation trials with concurrent or delayed visual feedback, followed by 15 veridical feedback trials in which aftereffects were assessed. Subsequently, participants completed 50 adaptation trials with concurrent or delayed feedback, followed by another 15

veridical feedback trials. The testing order was counterbalanced. Results: In controls, delayed and concurrent feedback resulted in similar rate and extent of error reduction, and aftereffects of similar magnitude and persistence. In PD, error reduction with delayed feedback was slightly slower than with concurrent feedback, although both delayed and concurrent feedback resulted in aftereffects of similar magnitude and persistence. Conclusions: Delayed visual feedback combined with undemanding adaptation conditions (30° rotation, single target) resulted in large aftereffects that decayed trial-by-trial, suggesting the formation of an adapted internal model. Hence, the simultaneity of visual feedback during visuomotor adaptation may not be crucial to the updating of an internal model. The slower error reduction with delayed visual feedback in PD but not in controls suggests a greater sensitivity to delayed visual feedback in PD.

Title: Boosting implicit sequence learning by hypnosis

Authors: *D. NEMETH[1,2]
[1]Inst. of Psychology, Univ. of Szeged, Szeged, Hungary; [2]Imaging Res. Ctr., Univ. of Texas, Austin, Austin, TX

Abstract: Human learning and memory depend on multiple cognitive systems related to dissociable brain structures. These systems interact not only in cooperative but sometimes competitive ways in optimizing performance. It has been previously demonstrated that functional brain connectivity is reduced in hypnosis, and this is especially typical for frontal areas. The main question of our study was how the disruption of frontal lobe functions affects performance in basal-ganglia dependent sequence learning. Fourteen highly hypnotizable, healthy adults participated in the experiment. Sequence learning was measured by the Alternating Serial Reaction Time (ASRT) task. Participants performed the ASRT task in waking alert and hypnotic state. We found improved sequence learning in the hypnosis condition compared to the alert condition. Our result provides support for the idea that learning and memory processes may not only involve the engagement of specific neuroplastic mechanisms, but may also rely upon the disengagement of interacting brain systems. The improved sequence learning in hypnosis could

be attributed to the reduction of interconnectivity between brain areas, especially the connections of the frontal lobe, which results in the disruption of attentional control and executive system. This result sheds light not only on the competitive nature of brain systems in cognitive processes, but also could lead to further research on improving human skill learning.

Title: Task-specific effect of tDCS on motor learning

Authors: *C. M. SAUCEDO[1], X. ZHANG[1], N. WENDEROTH[1,2]
[1]Katholieke Univ. Leuven, Heverlee, Belgium; [2]Dept. Hlth. Sci. and Technol., Zurich, Switzerland

Abstract: Anodal transcranial Direct Current Stimulation (tDCS) enhances motor skill learning when applied to the human primary motor cortex (M1) of healthy controls and in patients [1-4]. However, it remains unclear whether tDCS improves motor learning in a general manner or whether there is a task-specific effect. In this study, we tested the effect of tDCS in two different motor tasks: (1) sequential finger sequence task (SFTT) and (2) Sequential Isometric Pinch Force Task (SIPFT).
Thirty-two healthy subjects participated in this double-blind, sham-controlled cross-over designed study. All subjects were randomly assigned to an anodal-tDCS group or sham-group. We applied tDCS over the primary motor cortex (M1) while subjects performed the motor task. Two different sessions (session interval>1 month) were performed, with the task-order randomized across participants. Motor training of each task consisted of 20 min training for 3 continuous days. Retention tests were performed on the final training day and one week after the training.
Learning scores were calculated and compared using a mixed model ANOVA analysis. The results showed that for both tDCS groups there was an overall improvement of scores across training ($p<0.001$). Anodal tDCS showed more improvement compared to sham, in both motor

tasks, but this effect did not reach significance. In the SFTT task, a significant interaction between the TIME of stimulation (pre, training, post, RT) and TYPE of stimulation (anodal/sham) was found (p=0.01), with the greatest improvement by anodal tDCS being at the 20 min retention test (p=0.01). On the other hand, the SIPFT task showed the greatest improvement in the 1 week retention test (p=0.03).
These findings suggest that anodal tDCS applied over M1 appears to improve motor skill acquisition but there might be task dependent aspects as well. However, it is important to note that group differences across Anodal vs. Sham stimulation cannot be excluded in this study design. Therefore, to further confirm these results a cross-over design across types of tDCS stimulation will be included as well as a screening for the brain derived neurotrophic factor (BDNF) genotype of our participants to investigate if BDNF mediates the beneficial effect of tDCS.

Title: The role of the primary motor cortex in implicit learning and the processing of reward.

Authors: *L. WILKINSON, E. MOOSHAGIAN, T. ZIMMERMANN, J. LEWIS, E. WASSERMANN
Natl. Inst. of Neurolog. Disorders and Stroke, NIH, Bethesda, MD

Abstract: The basal ganglia and its cortical connections, including the primary motor cortex (M1) play an important role in both implicit/unconscious motor sequence learning and processing of reward. Continuous burst transcranial magnetic stimulation (cTBS) reduces in motor cortex excitability. We examined the effect of cTBS over M1on implicit sequence learning with and without reward, using a probabilistic serial reaction time paradigm. We investigated

implicit sequence learning with and without reward in two healthy groups after cTBS to M1 or sham. There was no overall effect of reward on learning. However, cTBS produced more impairment of learning in the unrewarded than the rewarded condition. Reward appears to protect learning against the effect of cTBS to M1 and may be a way of overcoming learning impairments in clinical settings.

Title: Resting-state motor network coherence decreases with long-term motor learning

Authors: *C. SAMPAIO-BAPTISTA, N. FILIPPINI, J. SCHOLZ, H. JOHANSEN-BERG
Univ. of Oxford, Oxford, United Kingdom

Abstract: Introduction: Motor skill learning induces structural and functional plasticity in the brain (e.g. Scholz et al., 2009). While motor learning is known to involve several brain areas that work as a circuit (e.g. Doyon & Ungerleider, 2002), most fMRI studies have focused on discrete brain activation rather than interactive networks. The resting brain exhibits spontaneous activity that forms distinct temporally correlated networks. The functional meaning of these resting-state networks is unknown, although some have suggested a role in memory consolidation, rehearsal or future preparation (Buckner & Vincent, 2007) as well as in motor learning (Albert, et al., 2009; Ma et al., 2011). Here, we tested whether long-term motor learning alters resting state network coherence and whether this relates to performance.
Methods: Naïve participants (n=20) were scanned before and after 6 weeks of juggling practice (30 minutes/day, 5 days/week). A control group (n=20) was scanned twice 6 weeks apart. Whole-brain functional imaging was performed while participants lay at rest with eyes open. Preprocessed data was used to identify previously described resting-state networks with IndependentComponent Analysis (ICA) and thresholded group ICA outputs were used to define masks of the sensorimotor and default mode networks. A dual-regression approach was used to

extract subject-specific mean network values within these masks for each timepoint (Filippini et al., 2009). SPSS was used to test for differences between groups over time using a repeated measures ANOVA and to test for correlations with behaviour using Pearson's correlation.
Results:Long-term learning altered resting brain activity in a network specific manner.For the sensorimotor network only, learning decreased coherence (group x time interaction; $F(1,38) = 5.02$; $p < 0.05$) (Fig 1a). This decrease correlated with performance ($R = - 0.43$; $p < 0.05$) (Fig 1b).
Conclusion:Long-term motor learning decreases the resting-state motor network coherence in a behaviourally-relevant manner.

Title: Resting state connectivity predicts implicit sequence learning performance

Authors: *C. STILLMAN[1], E. M. GORDON[2], H. H. FELDMAN[1], J. R. SIMON[3], C. J. VAIDYA[1,4], J. H. HOWARD[5,1,6], D. V. HOWARD[1]

Abstract: Our ability to rapidly acquire and integrate complex probabilistic associations is essential for many everyday activities. The neural basis of this type of learning has been explored using both functional MRI (fMRI) and diffusion tensor imaging techniques. These studies indicate that implicit associative learning is supported by the activation of a neural system including the striatum, hippocampus, and prefrontal cortex, and is mediated by the structural integrity of white matter tracts connecting these regions (Bennett et al., 2011, Simon, Vaidya, et al., 2011). Recent research using resting state fMRI suggests that brain regions which are both structurally connected and coactivated during cognitive tasks also form functional networks during rest. The present goal was to explore if the degree of coherence in the spontaneous activity in these regions at rest relates to implicit learning performance.
Twenty-two subjects completed three sessions of the Triplets Learning Task (TLT), a probabilistic sequence-learning task in which participants respond to the location of a target event in sequences of three events, or "triplets". Unbeknownst to participants, some triplets of events occur with high probability (HP) and others with low probability (LP). Implicit sequence learning is measured by subtracting response times to HP triplets from LP triplets. There was significant learning in all three sessions (all *p*s < .001), with most participants attaining their highest learning score in the final session. Resting state fMRI data were also collected for these subjects. Using the time series extracted from a bilateral dorsal caudate (DC) seed, a region where individual differences in functioning have been associated with learning performance in the TLT (Simon, Stollstorff, et al. 2011), voxel-wise whole brain analyses were conducted in SPM8 to generate a connectivity map of the DC for each subject. These maps were then entered into a regression model in which learning scores from the final session were entered as the sole predictor.
Higher learning scores were associated with stronger resting state connectivity between the DC and right hippocampus, bilateral parahippocampal gyri, and left inferior frontal gyrus. This pattern of results suggests that the DC, hippocampal and specific frontal regions form a functional network at rest that supports implicit associative learning during the TLT.

Title: The N400 reflects response predictability in an implicit sequence learning task

Authors: *S. A. KISER[1], R. FULLER[2], A. B. FORMAN-ALBERTI[2], K. M. O'NEIL[2], D. V. HOWARD[3], J. H. HOWARD, Jr.[2,3]
[1]Psychology Dept., [2]Psychology, The Catholic Univ. of America, Washington, DC; [3]Georgetown Univ., Washington, DC

Abstract: The N400 component of the ERP has been demonstrated in semantic priming (Kutas & Federmeier, 2011), masked priming (Misra & Holcomb, 2003) and recognition familiarity tasks (Rugg & Curran, 2007). However, there is debate about whether the N400 reflects explicit or implicit processes. In the present study we demonstrate a link between the N400 and response predictability in implicit sequence learning using the triplets learning task (TLT; Howard et al., 2008).
Fifteen college-age students completed three, 500-trial sessions of the TLT. On each trial in the TLT three consecutive “lights” appear on a computer screen. Participants observe the first two “cue” lights and respond to the last, “target” light by pressing a corresponding key. Unbeknownst to them, the first light predicts the target location on 80% of the trials (high frequency triplets) and another location on 20% of the trials (low frequency triplets). Event-related potentials were recorded and time-locked to the target stimulus. After the TLT, participants responded to a post-experimental interview and performed a recognition task to assess explicit knowledge.
A repeated-measures ANOVA conducted on reaction times revealed main effects of session and triplet type (high vs. low frequency triplets), as well as a significant interaction between session and triplet-type indicating that both overall skill learning and sequence-specific learning occurred. Results from the rating task and post experimental interview confirmed that learning was implicit.
ERP data were collected using the 64 channel Bio-Semi ActiveView System and analyzed offline using EMSE 5.2. Peak detection analysis was performed on the N400 component (300-500ms after stimulus onset) at electrode FCz using the 10-20 system. Analyses of mean amplitude revealed a significantly smaller N400 for the high frequency compared to low frequency triplets. Thus, the N400 magnitude corresponds to the predictive relationship learned

implicitly.
The present study contributes to the on-going debate as to the nature of the N400 component. Previous studies using semantic and masked priming as well as familiarity recognition tasks have shown that late occurring negativities are modulated by standard and deviant stimuli. The present study revealed a similar pattern for high and low frequency triplets in the TLT. These findings are the first to demonstrate N400 in a purely implicit learning task. This suggests that a common form of implicit priming might underlie N400 effects. Future research should use neuroimaging techniques to determine the generator of the N400.

Title: Cortical networks underlying vocal and instrumental musical training in Adults

Authors: *N. C. SINGH, M. SHARDA
Natl. Brain Res. Ctr., Manesar, India

Abstract: INTRODUCTION: Long-term musical training involves development of skill-based learning and procedural memory and has a dynamic influence on the structure and function of the brain. It involves not only fine-tuning of sensorimotor processes but also an extensive refinement of the vocal apparatus in case of singers. The coincident presence of vocal and instrumental learning in the same individual gives us a unique opportunity to study the effect of this ‘dual-mode’ training on the brain.
METHODS: 29 participants performed a passive listening in an MRI scanner. The stimuli were presented in a sparse-sampled event related design with TR=10s and consisted of 3 conditions - spoken words, sung words and piano tones. Stimuli were bisyllabic verbs and nouns. 90 volumes were collected per participant along with a high-resolution T1 image. Processing was done using SPM5 and VBM8. The participants were adults with mean age 29.2 years and belonged to 3 groups - UNT(10): musically untrained, AMA(10): amateurs with childhood musical training and PRO(9):Professionals with atleast 10 years of training.
RESULTS: We used a 3 X 3 flexible factorial design to identify average and main effects of Condition (spoken word, sung word or piano tone) and Group (UNT, AMA, PRO). Average

effect of condition was seen extensively in bilateral temporal networks for both spoken and sung word perception. The activity was restricted to the right auditory cortex for perception of tones. The main effect of condition was localized to the bilateral temporal regions and right precentral gyrus. The average effect of group also differed across the three, with both the UNT and PRO recruiting bilateral temporal regions but the AMA only a small cluster in right STG. The main effect of group revealed peak activations in bilateral caudate. A subsequent structural analysis using voxel-based morphometry also revealed increased gray matter volume bilaterally in the caudate nucleus. A correlation between the parameter estimate values in the functional activation cluster from the main effect of group and the gray matter volume in the regions from the structural analysis revealed a significant relationship between the two.
CONCLUSIONS: Our main findings highlight the role of the caudate nucleus in extensive vocal and instrumental training in musicians. The caudate nucleus is a part of the basal ganglia and plays a role in many cognitive processes. However, this is the first report of a major role of the caudate in skill-based vocal and instrument learning in terms of both increased functional activation as well as increased gray matter volume. Future research will focus on understanding the role of the caudate in these processes.

Title: Muscle relaxation of the foot reduces the corticospinal excitability of the hand muscles

Authors: *K. KOUKI, ESQ[1], M. NOBUAKI[2], M. TETSURO[3], K. KAZUYUKI[4]
[1]Kouki Kato, Tokorozawa, Japan; [2]Advanced Telecommunications Res. Inst. Intl., Kyoto, Japan; [3]Col. of Economics, Nihon Univ., Tokyo, Japan; [4]Fac. of Sport Sciences, Waseda university, Saitama, Japan

Abstract: [Introduction]
Muscle relaxation is an important factor to make good performances in sports, but the mechanism has not been well understood. It has been suggested that muscle relaxation is accomplished by an active process in the brain, and not the mere end of contraction. Transcranial magnetic stimulation (TMS) study suggested that corticospinal excitability was reduced just prior to the voluntary muscle relaxation [1]. We have observed that EMG level of contraction in

one hand decreased during the relaxation of the ipsilateral foot. The purpose of the present study was to clarify the effects of relaxation of foot muscles on the corticospinal excitability of hand.
[Methods]
Nine subjects performed relaxation of the right foot dorsiflexor immediately in response to an audio cue. The completion of relaxation (offset-time) was defined by the offset of the EMG. TMS stimulation was delivered to the hand area of the left mortor cortex at -100, -50, 0, 50, and 100 ms (TMS stimuli-time) from the offset-time predetermined from 10 pre-trials without stimulation. Motor evoked potentials (MEPs) were recorded from the wrist extensor (ECR) and flexor muscles (FCR). Actual TMS timing was determined from the period between the offset-time of each trial to TMS stimuli-time. Corticospinal excitability was assessed by peak-to-peak amplitude of MEPs.
[Results]
The MEP amplitudes of ECR and FCR were higher in the periods of "~ -101 ms" than that in the resting condition. The MEP amplitude of ECR was smaller in the period of "100 ms~" than that in the resting condition. The MEP amplitude of FCR was smaller in the periods of "50~99 ms" and "100 ms~" than that in the resting condition.
[Discussion]
Corticospinal excitabilities of both ECR and FCR increased before ankle relaxation compared to resting condition. After ankle relaxation, on the other hand, corticospinal excitability decreased compared to resting condition. It is suggested that inhibitory commands were conveyed not only to the relaxing muscle (TA) but also to other resting muscles (ECR and FCR) during muscle relaxation. In conclusion, relaxation of foot dorsiflexor decreased in the excitabilities of hand muscle, both flexor and extensor.

Abstract: The frontal lobes play a critical role in temporal order memory for sequences of stimuli. Since Huntington's disease (HD) results in frontal-striatal circuit dysfunction, temporal order memory may be particularly sensitive to HD neuropathological degeneration. The current study examined temporal order memory in patients diagnosed with manifest HD and matched controls. Participants completed a visuospatial temporal order memory task involving manipulations of the temporal separation between two spatial locations in a random sequence of locations that varied on each trial. Studies suggest that there is more interference for temporally proximal stimuli relative to temporally distal stimuli. We found that the performance of HD patients and controls improved as a function of increased temporal separation. However, HD patients demonstrated significant impairments relative to controls, suggesting that temporal order memory is impaired in HD patients even when temporal interference is minimal. The findings identify a fundamental, yet relatively unexamined, processing deficit that may effect the execution of various daily living skills in individuals with HD.

Title: Psychophysiological investigation of attentional processes during motor skill learning

Authors: *J. C. RIETSCHEL[1,2], R. N. GOODMAN[1], C. G. MCDONALD[4], M. W. MILLER[2], L. JONES-LUSH[3], G. F. WITTENBERG[3,1], B. D. HATFIELD[2]
[1]VA, Baltimore, MD; [2]Univ. of Maryland, College Park, MD; [3]Univ. of Maryland, Baltimore, MD; [4]George Mason Univ., Fairfax, VA

Abstract: As one becomes proficient at a motor task the attentional demand required to perform that task is reduced. Behavioral evidence suggests that experienced individuals possess greater attentional reserve during task execution compared to novices, such that, they are better able to cope with additional, possibly unexpected, challenges. This advantage may be the result of streamlining the neural processes underlying motor planning and execution over the course of learning. Such psychomotor efficiency reduces the demand on cortical resources imposed by the primary task such that they are available for coping with challenge beyond that of the task. The aim of this study was to provide neurobiological evidence of the positive relationship between motor skill and attentional reserve.

Twenty-one participants were randomly assigned to one of two groups, a group that learned a novel visuomotor distortion task, learning group (LG), and a control group (CG) that performed the same task with no distortion (i.e., no learning). For the duration of the task, event-related brain potentials (ERPs) elicited by a set of novel stimuli were recorded. The dynamic modulation of ERP component amplitude was used as an index of attentional reserve. We predicted that component amplitudes would initially be diminished in the LG relative to the CG, but that there would be a progressive increase in amplitude as a function of learning; by contrast, we predicted that ERP component amplitudes would remain relatively stable in the CG.

Importantly, task performance, as measured by initial directional error, was initially worse in the LG relative to CG and significantly improved over the course of exposure, whereas the CG's performance was stable. This suggests the visuomotor distortion task employed was successful in serving as a model of motor skill acquisition. Analyses of the ERPs elicited by the auditory probes revealed that the exogenous components, N1 and P2, were not different between the two groups and did not change over the course of learning suggesting that early sensory processing was comparable between the two groups. Notably, the novelty P3 component_an index of the involuntary orienting of attention_was initially attenuated in the LG relative to the CG, but progressively increased in amplitude as a function of learning in the LG only. This suggests that attentional reserve increased as a function of motor skill acquisition, such that greater attentional resources were available to process the auditory probes.

The current study provides psychophysiological evidence that attentional reserve increases as a function of motor skill acquisition.

Title: Rehabilitation Engineering for limb impairment using robots: Notes about rhythmic reinforcement learning for locomotion

Authors: *J. F. GOMEZ[1], A. TORRES[2], A. L. GOMEZ_MOLINA[3], A. RESTREPO[4]
[1]Intnal Group of Neuro Cra 64c#48-94(603), Medellin, Colombia; [2]EIA-CES Escuela de Ingenieria de Antioquia-Universidad CES, Medellin, Colombia; [3]Intnal Group of Neuro (section), Kansas, MO; [4](neuro)Informatica y Sistemas, Univ. EAFIT, Universidad EAFIT, Colombia

Abstract: INTRODUCTION. 1. Rhythms are essential in the formation of connectivity during development (Yuste 1992). 2. Bilateral movements permit inter-hemispheric facilitation (Parlow and Dewey, 1991). 3. Movement plays an important role in recovery. Movement and function are coupled in a positive feedback. Using the ideas of machine learning, we might consider activity not just an "action" but also a "goal". We then hypothesize that:
A. An important early drive to repair dysfunctional networks of lower and also upper limbs is by stimulating the production of locomotion-related rhythms. Since the circuitry of the limbs is similar, patterns of locomotion and turning might facilitate inter-limb reinforcement and transfer of information.
B. Robot-activated movements, if they are synchronized with cortical drive (using EEG/EMG, see Cheron G et.al 2012), generate proprioceptive and somatosentory signals related to locomotion, therefore helping in the recovery process. Increasing the movement of the dysfunctional hand in locomotion can restore the reconnection of their networks and the associated manipulation skills.
METHODS. Using theoretical tools (control and reinforcement learning algorithms) we present a sketch of a robotic system for rehabilitation assuming that A and B are correct.
RESULTS. (1) Portable robots that block/unblock movements in synchrony with locomotion can improve constraint-induced-movement therapies. (2) A robotic or biomechanical system that only allows repetitive movements and synergies between affected and intact sides creates a reinforcement learning scenario with an optimal police and an optimal-state-value function. Fig.1.
CONCLUSIONS. (1) Spontaneous bilateral rhythmic patterns based on inter-hemispheric facilitation can be stimulated using reinforcement learning. (2) Reinforcement facilitate persistent movement of affected side post-training (spontaneous arm use) if dose of therapy is above a threshold (see Han CE 2008). (3) Bilateral errors might increase transfer of training and interhemispheric reinforcement of activity.

Title: The contribution of exploration to learning in young infants

Authors: *B. A. SARGENT, S. S. KIM, N. SCHWEIGHOFER, L. FETTERS
Div. of Biokinesiology and Physical Therapy, USC, Los Angeles, CA

Abstract: A critical issue in the study of infant development is to identify the processes by which task-specific action emerges. It has been previously
suggested that spontaneous movements allow infants to learn task-specific action via reward-based learning. In theoretical models of reward-based learning, maximizing future rewards requires goal-directed exploration: exploration of task-unspecific actions should rapidly decrease and exploration of task-specific action should be modulated as a function of the change in rate of return. To test whether young infants exhibit such a behavior, we designed a two-day experiment in which 3 month old infants were placed supine under a musical mobile. For the 6 minutes immediately following a 2 minute baseline, kicking over a threshold activated music and movement from the mobile. The threshold was calibrated for each infant from baseline data along the dimension perpendicular to the support surface (z). All infants learned to activate the mobile with increasing frequency over the two days. There was a significant increase in the variance in the z dimension (task-specific) accompanied by a decrease in the variance in the x dimension (non-task-specific, parallel to the support surface). To further dissociate the changes in variance in the z direction due to learning to changes in variance due to exploration, we modeled the leg as a rod with 2 degrees of freedom at the hip, and developed and compared a number of reward-based learning models (such as policy-gradient models and value-based models). The difference between the best fitting model output and movement trajectory data from each infant at each time step was then taken as a combination of exploration and motor noise-related variance. Our findings provide the first quantification of the contribution of exploration to the early learning of task-specific leg action of 3 month old infants.

Title: Emotion is dissociable from error during motor learning

Authors: S. FESTINI, S. PRESTON, P. REUTER-LORENZ, *R. D. SEIDLER
Univ. Michigan, ANN ARBOR, MI

Abstract: Two prominent theories of motor learning include error-based learning and use-dependent learning. With error-based learning, the magnitude of the error that an individual produces while performing a movement tends to influence similar subsequent movements because the individual tries to correct the error on future attempts. Use-dependent learning posits that the current movement is influenced by the most recently executed movement, and it is shown to be distinct from error-based learning. Neither theory takes into account the affective state of the learner, however, even though emotion is known to influence cognitive and motor performance. For instance, positive affect can reduce the size of the error-related negativity (ERN), an electrophysiological measure of error-processing. Thus, in addition to error-based learning and use-dependent learning, the learner's affective state may also influence subsequent motor behavior. The current study aimed to determine if emotion is dissociable from error during motor learning, and whether emotion uniquely contributes to motor learning.

Using prism adaptation, we assessed the influence of emotion on motor learning in a trial-by-trial fashion. Participants performed a dart-throwing task, in which they earned points for accurate throws. The target location was assigned the highest number of points, and two nearby, but non-adjacent, locations were assigned smaller point values. Individuals were instructed to try to maximize their score. Error and affect were measured on each trial. Specifically, participants rated how ecstatic, disappointed, and frustrated they felt after each throw. After performing a set of baseline trials, participants donned prism lenses that shifted their visual field 30 degrees to the left. Participants had to learn to adjust their dart-throwing to the visual perturbation and had to readjust after the prism lenses were removed.

Results suggest that the subjective emotional response to motor performance is dissociable from the size of the error made. Affective ratings were not strongly correlated with error magnitude. Instead, emotional ratings were more closely associated with the points earned on a given trial. Error-based learning was also evident, as the size of the error on a given trial was correlated with the change in error on the next trial. The influence of the learner's affective state on prism adaptation and aftereffects will also be discussed.

Title: Mirror neurons and P3 while observing and executing a visual oddball task.

Authors: L. E. PEÑA[1], *O. A. DIEZ-MARTINEZ[2]
[1]Psychology, Univ. de las Américas, P, Cholula, Puebla, Mexico; [2]Psychology, Univ. de las Américas, P, Cholula, Mexico

Abstract: Mirror neurons (MNs) transform specific sensory information into motor formats (Fabbri-Destro & Rizzolatti, 2008). They discharge both when an individual executes a specific motor act and when he observes a similar act being executed by others (Fabbri-Destro & Rizzolatti, 2008; Gallese & Goldman, 1998; Oberman et al., 2007; Rizzolatti, 2005). MNs allow recognition of actions performed by others (Buccino et al., 2001) and comprehension of action and intention, imitation, speech and appreciation of emotions (Calvo-Merino et al., 2005; Fabbri-Destro & Rizzolatti, 2008). We studied the influence of MNs upon event related potentials (ERPs). Our aim was to determine if MNs contribute to generate the P3 component in individuals that observe others performing a visual oddball task (VOT). We analyzed if the ERPs during observation were similar to those generated while executing the task. The sample consisted of 17 students (5 women, 12 men). We recorded their ERPs in three different conditions (observation: participants observed another individual executing a VOT; execution: the subject performed the VOT; and control: participants observed animation videos). We analyzed the data using a dependent samples t-test and an ANOVA for repeated measures. We studied P3 potentials obtained from the posterior middle frontal (PMF), middle central (MC) and middle parietal (MP) regions. Spectral analysis of the μ rhythm was also done. Subjects were able to understand the VOT and execute it correctly without receiving instructions. We recorded P3s in PMF and MC regions in subjects observing others executing the task. P3s were not found in MP region. We infer that, when the subject was an observer, he was trying to figure out what the performer was doing in order to imitate him. Thus, he was more focused on correctly representing motor acts of actions to be imitated, than in maintenance of working memory. No P3s were observed during the control condition ($F_{2,15}$=70.332, $p<0.05$). Except for its increased latency, the P3 recorded during observation in PMF and MC regions was not significantly different from that obtained during execution. Furthermore, suppression of μ rhythm during task observation and execution suggests that our findings are a result of the activation of MNs.

Title: Sleep restores the potential to undergo learning induced increases of corticomotor excitability: New evidence in line with the synaptic downscaling hypothesis

Authors: *T. T. DE BEUKELAAR[1], J. VAN SOOM[2], N. WENDEROTH[3,1]
[1]Biomed. Kinesiology, [2]Catholic Univ. of Leuven, Heverlee, Belgium; [3]Dept. Hlth. Sci. and Technol., Neural Control of Movement Lab, ETH, Zurich, Switzerland

Abstract: "Synaptic downscaling" is hypothesized to be an important function of sleep such that previously potentiated synapses are reset. This is necessary for the acquisition of new memories during subsequent wakefulness. Currently, however, there is little experimental evidence available supporting this hypothesis. Here we used Transcranial Magnetic Stimulation (TMS) to quantify learning induced increases of corticomotor excitability, i.e. a marker of neuroplasticity. We asked whether (i) neuroplasticity would be large when acquiring a new motor task in the morning and reduced when doing so in the evening, and whether (ii) the potential to undergo learning related changes would be restored again after one night of sleep.
19 right-handed subjects were randomly assigned to one of two groups: the *WAKE-group* acquired a 5-element sequence at 8 a.m. and a different 5-element sequence at 8 p.m. The *SLEEP*-group followed the identical protocol but acquired the first sequence at 8 p.m. and the second sequence at 8 a.m. after one night of sleep. The sequences had to be performed as quickly and accurately as possible. Neuroplasticity was quantified by measuring Input-Output (I/O) curves before and after the learning task. Therefore, TMS was applied over the hotspot of First Dorsal Interosseus (FDI) with intensities ranging from 90% to 190% of Rest Motor Threshold (RMT) in steps of 25%. In the *WAKE-group*, repeated measures ANOVA revealed a significantly larger increase from pre- to post-learning in the morning than in the evening. Moreover, pre-learning excitability was higher in the evening than in the morning ($p<.05$). These findings are in line with the hypothesis that synapses become potentiated during the day; such that the potential for synaptic plasticity becomes smaller the longer subjects are awake.
In the *SLEEP-group*, the opposite pattern of neuroplasticity was observed ($p<.05$) such that changes of corticomotor excitability from pre- to post-learning were smaller in the evening than in the morning when tested after a sufficient amount of sleep. This indicates that the potential for synaptic plasticity was restored during a night of sleep.
At the behavioral level, both groups improved significantly during training with no differences between groups or between learning sessions. In conclusion, in line with the synaptic downscaling hypothesis, our neural data provide new evidence on the interaction between sleep and neuroplasticity. Even though quantifiable at the neural level, these mechanisms do not appear to induce significant effects at the behavioral level, at least not when probed with a relatively simple task as in the present study.

Title: Learning a spatial sequence activates a fronto-parietal network and leaves local traces in the resting state EEG

Authors: *C. MOISELLO[1], H. B. MEZIANE[1], B. PERFETTI[2], N. VOUTSINAS[1], S. KVINT[1], G. TONONI[3], M. GHILARDI[1]
[1]Physiol. and Pharmacol., CCNY, NEW YORK, NY; [2]Univ. "G. d'Annunzio", Chieti, Italy; [3]Univ. of Wisconsin, Madison, WI

Abstract: There is strong evidence from imaging studies that activity in frontal and parietal regions plays a fundamental role in the attentional and memory processes involved in the acquisition of spatial sequences. However, little is known about the fine dynamics of neural activations and interactions underlying such complex process. Here, we used high-density EEG and determined: first, the temporal evolution of spectral changes during different stages of sequence acquisition; second, whether learning induces changes in the resting state oscillatory activity in the areas that participated in the learning process, i.e. a local trace in the resting state EEG.
High density-EEG was recorded in 21 normal subjects before, during and after the acquisition of the order of a fixed spatial target sequence in five blocks (VSEQ) and during the presentation of targets in random order (VRAN). The comparison of the average spectral power of the VSEQ blocks to VRAN blocks revealed significant differences in two main regions, a right parieto-occipital and a centro-frontal region, for the alpha and theta bands. Specifically, in the right

parieto-occipital area, VSEQ compared to VRAN showed: 1. theta power decrease before the stimulus; 2. alpha power decrease, 750 to 1000 ms after the stimulus. Over the centro-frontal regions, theta power significantly increased in VSEQ compared to VRAN from 250 to 500 ms post-stimulus. In general, such differences were strongest in the first VSEQ block and decreased in the last VSEQ block. The changes in frontal theta power during the five blocks of VSEQ were positively correlated with the speed of learning, measured from verbal reports collected at the end of each VSEQ block. After the task, resting-state eyes-open recordings showed an increase of alpha activity in the right parieto-occipital region and a decrease of theta activity in the centro-frontal region.
We conclude that the alpha and theta changes during learning, in central frontal region and right parieto-occipital regions, are related to the attentional and control processes that are higher in the early stages of sequence acquisition and decrease when the sequence has been fully acquired. On the other hand, the changes in those same regions in the resting state after the task may represent an EEG trace of learning and a hallmark of use-dependent plasticity.

Title: Implicit visuomotor sequence learning in a target-directed postural control task

Authors: S. R. CALJOUW[1], S. WOLDHEK[1], H. G. VAN KEEKEN[1], *R. M. BONGERS[2], C. J. C. LAMOTH[1]
[1]Ctr. for Human Movement Sci., Univ. of Groningen, Univ. Med. Ctr. Groningen, Groningen, Netherlands; [2]Human Movement Sci., Univ. of Groningen, Groningen, Netherlands

Abstract: In the serial reaction time (SRT) task participants press repeatedly keys that spatially correspond with the location of sequential targets. Practice will improve anticipation of the target location, thus improving motor preparation and hence faster reaction times for the next response in the sequence. This learning can occur implicitly and is therefore, in contrast to explicit learning, thought to be preserved with aging and when performing cognitively demanding dual tasks. Nevertheless, the SRT tasks involve only simple key presses making the merits of implicit sequence learning for motor tasks that involve more complex movement dynamics in elderly

unknown. A motor version, involving postural control, of the SRT task was conducted in a Virtual Reality lab (CAREN) with both young (age 23.9 ± 4.3) and older subjects (age 67.9 ± 2.5 years). A dot representing centre of pressure displacements on a screen in front of the person had to be moved by redistributing weight while standing on a force platform, from a central position on the screen to a target in one of five locations and back. In the explicit and implicit learning phase targets were presented in a 45 times repeating five-target fixed sequence. Different sequence learning conditions were performed, an implicit condition with a concurrent spatial dual task and two explicit conditions, one with and one without a dual-task. The participants improved their performance over sequence blocks, also in the implicit condition where the included participants were all completely unaware of the presented sequence. When a random block was introduced all movement parameters returned to baseline, indicating that the performance improvement was related to the sequence and not a general practice effect. Interestingly, target location anticipation (initiation time and accuracy of initial direction) was positively influenced only when people were aware of the target sequence and weren't distracted by a dual task. When progressing towards the target the speed and accuracy of the movement increased over time in all three learning conditions. So, movement execution, which is considered a more automatic process, was improved by implicit sequence learning whereas target anticipation was only improved by explicit sequence learning. Although the older participants moved generally slower and less accurate, learning effects were similar compared to the younger participants in all sequence learning conditions. So, we could not confirm more age-related impairments in explicit than in implicit motor sequence learning on this postural control task.

Title: Prospective optimization by reallocation of computational resources.

Authors: D. LEE[1], *J. SNIDER[1], H. POIZNER[1], S. GEPSHTEIN[2]
[1]Inst. for Neural Computation, UCSD, La Jolla, CA; [2]Systems Neurobio. Labs., The Salk Inst. for Biol. Studies, La Jolla, CA

Abstract: We investigated the human ability to optimize action over multiple future steps in rapidly changing risky environments. Subjects sat in front of a touch screen on which a grid of disks of different sizes (the "stimulus") scrolled down at a variable speed. The task was to maximize the score by touching one disk at a time in a rapid sequence. The positive score from touching a disk was proportional to disk size, while missing a disk incurred a negative score. Auditory and visual feedback conveyed outcomes of every action. Subjects were allowed to touch one disk per row, moving up on the screen. Only one of two disks could be touched in row n+1, adjacent to the disk just touched in row n, such that every choice constrained the part of the stimulus that could be touched in the future. This way, the ability to take into account multiple upcoming rows would yield a better total score. To infer the number of upcoming rows (“depth of computation” D) used in action selection, we counted how often human choices overlapped with choices of ideal planners characterized by different values of D and by different rate of recomputation (R) of action sequences. We found that evidence for D was a decreasing function of distance from the present row to upcoming rows: subjects relied on the immediately upcoming rows more than the remote rows. But as the time pressure decreased (at a lower speed of the stimulus), subjects were able to increase D and thus obtain larger winnings. Notably, the increased evidence for large D was associated with decreased evidence for small D, as if subjects reallocated their computational resources across D. We measured the utility of different disk sizes by comparing evidence for D in actual stimuli with the evidence computed for stimuli where only the largest disk sizes were present, or only the two largest sizes were present, etc. This analysis showed that subjects did not exclusively rely on the larger disks. Indeed, subjects used almost all disk sizes, although large disks had a greater weight in decision making than small disks. The results demonstrate that the ability for rapid decision making is flexible in two respects. First, humans can rapidly recompute the course of action over multiple future steps as new information enters the scope of computation. Second, humans can expand their depth of computation as task difficulty decreases, but the expansion has a cost: a decreased ability to use immediate information, revealing a limit to computational resources that are selectively allocated to different aspects of future actions.

Title: Learning joint actions: Behavioral correlates

Authors: *D. A. GUFFREY, S. HELMS TILLERY, C. A. BUNEO
Sch. of Biol. and Hlth. Systems Engin., Arizona State Univ., Tempe, AZ

Abstract: Joint actions involve two or more agents coordinating their behavior in space and time to perform a particular task. Despite the fact that these types of actions are very commonly performed in everyday life, surprisingly little is known about how joint actions are learned and represented in the brain. Here we addressed the following question: How are joint motor actions learned in the absence of direct visual, auditory and haptic cues provided by another agent? Two pairs of human subjects were examined during the learning of a virtual reality based joint action task. The task involved moving a cursor from the center of a visual display outward to one of four peripheral targets, and returning to center within a two second time period. Importantly, motion of the cursor depended on the arm movements of both subjects, i.e. the mean of their simultaneous (but not necessarily synchronous) individual actions. Subjects were provided with cursor feedback but biomotion cues, i.e. visual cues of the moving arms and other body parts, were withheld. Subjects were also instructed not to provide auditory cues to one another. However, auditory cues indicating trial success/failure were provided. In this task, the mapping between subject motion and cursor motion was not veridical but involved a visuomotor rotation of 30 degrees that was applied to either one or both subjects in separate blocks. Subjects also performed an initial control block and three intervening deadaptation blocks where no rotation was applied. Each block required the successful completion of 15 trials per target. Directional error on each trial was calculated as the angle between the ideal outward trajectory (vector connecting center of display to target), and the actual cursor trajectory (center to point of peak outward velocity). Learning was assessed by comparing the mean directional errors during the first and last 15 trials of each block. No differences in directional error were observed in the control block or the deadaptation blocks for either pair of subjects. In contrast, for 3/6 rotated blocks, directional errors were smaller in the last 15 trials than in the first 15 trials (t-test, $p<0.05$). The results suggest that pairs of subjects are able to adapt their coordinated movements under visuomotor rotation, even when the relationship between cursor movement and each subject's individual movements are ambiguous. Effects of rotation angle magnitude and direction, as well as temporal lag will be pursued in future experiments.

Title: Neural correlates of the retrieval of temporal order memory

Authors: *M. SUZUKI[1], J. OKUDA[1], A. UENO[2], Y. MATSUE[3], T. FUJII[2,3]
[1]Fac. of Computer Sci. and Engin., Kyoto Sangyo Univ., Kyoto, Japan; [2]Dept. of Behavioral Neurol. and Cognitive Neurosci., Tohoku Univ. Grad. Sch. of Med., Sendai, Japan; [3]Kansei Fukushi Res. Inst., Tohoku Fukushi Univ., Sendai, Japan

Abstract: Everyday episodes typically consist of a series of mini-events that unfold over time. Thus, accurate memory of an episode requires retrieval not only of its content and context, but also of the temporal relations between its constituent components. The hippocampus has been proposed to play a role in forming associations between temporally discontiguous events. The basal forebrain, along with the lateral prefrontal and orbitofrontal cortices, is also known to be important for the memory of temporal order between events. It remains unclear, however, how these regions contribute to neurocognitive processes involved in the retrieval of temporal order memory. To investigate this issue, we conducted an fMRI study with a temporal order judgment task, in which two test items with varying numbers of intervening trials at study were presented. On each study trial, subjects were presented with two words in succession (SOA = 3 seconds) and were asked to judge which item fits better with a picture of unfamiliar scene. They were then given a surprise memory test with fMRI. Test stimuli consisted of intact pairs (words identical to those in each study trial), rearranged pairs (words from different study trials), or new pairs. The temporal lags between words in the rearranged pairs varied from 36 to 144 study trials. Subjects were asked to determine which word in the test pair was presented more recently. We found that activities in different hippocampal regions were associated with the retrieval of temporal order information between items within the same study pair (intact) and across the different study pair (rearranged). In addition, correlation analyses revealed that the activity in the right MTL region decreased with the number of temporal lag, and that the activity in the right hippocampus and the left basal forebrain increased with the number of temporal lag. The present findings indicate that

the retrieval of temporal order memory is supported by dissociable neurocognitive processes depending on the difference in temporal lag between events.

Abstract: Memory is improved when effective strategies are employed during encoding. Recent psychological studies have reported that stimuli encoded with the strategy of survival judgments, in which participants judge whether the stimuli are necessary in the survival situation, are better remembered than stimuli encoded with other strategies. However, little is known about the neural mechanisms underlying the effects of survival judgments on memory. The current fMRI study investigated retrieval-related activations of memories encoded with the strategy of survival judgments. During encoding, 23 participants (10 females, mean age=20.6) were presented with Japanese words in four conditions, in each of which participants rated how the words were needed in the survival (S) or moving (M) situations, how the words were pleasant (P), or how many numbers of letters the words had (L). During retrieval, participants were presented with old and new words, and performed an old/new recognition test with confidence ratings. The fMRI analyses focused on data from the retrieval. Successful retrieval activity (SRA) for words encoded in each condition was identified by comparing activities between hits with high confidence and all misses. Behavioral data demonstrated that words encoded in S were

remembered more accurately than those in other conditions of encoding. fMRI data yielded three main findings. First, SRAs in the right middle frontal gyrus and bilateral precuneus were identified selectively in the retrieval of words encoded in S. Second, the left amygdala showed significant SRAs for words encoded in both S and P. Third, in the hippocampus, we found significant SRAs for words encoded in all conditions. These results suggest that possible network including the middle frontal gyrus, precuneus, amygdala and hippocampus could contribute to the memory enhancement by the encoding strategy of survival judgments.

Title: Neural populations in human posteromedial cortex display opposing responses during memory and numerical processing

Authors: *B. L. FOSTER, M. DASTJERDI, J. PARVIZI
Neurol. and Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Studies of the human default mode network (DMN) using functional brain imaging have revealed overlapping activation patterns within this network across various conditions of 'internal' self-referential processing. Conversely, overlapping deactivation is also observed for this network during tasks most simply classified as requiring 'externally' directed attention. Despite this progress in the functional imaging of the DMN, similar advances have not been made in the electrophysiological domain.
We addressed this limitation by obtaining interhemispheric intracranial recordings from the human posteromedial cortex (PMC), the central node of the DMN. Eight subjects, balanced for gender and hemisphere, performed a simple task that required true/false judgments of either internally directed memory statements (3 subtypes: i) self-episodic; ii) self-semantic; iii) self-judgment) or arithmetic equations. These stimuli were self-paced and randomly interleaved with five-second periods of rest fixation.
We observed late onset (>400 ms) increases in broad high-gamma (HG; 70-180 Hz) power within PMC subregions during episodic memory retrieval. These response features were not

significantly different between episodic events judged to be true or false. However, HG power was significantly reduced or absent when subjects retrieved self-referential semantic memories or responded to self-judgment statements, respectively. Conversely, a significant deactivation of HG power was observed during arithmetic calculation, the duration of which correlated with reaction time at the signal trial level. Strikingly, at each recording site, the magnitude of activation during episodic memory retrieval predicted the degree of suppression during arithmetic calculation.
These findings provide important anatomical and temporal details, at the neural population level, of PMC engagement during episodic memory retrieval and how the same populations show a significant reduction of activity for other conditions of self-referential content. Our findings are consistent with the view that those DMN regions suppressed during external attentional are indeed the same neural populations activated during more internally focused processes.

Title: The sensory cortical basis of true and false memory for motion

Authors: *J. M. KARANIAN, S. D. SLOTNICK
Psychology, Boston Col., Chestnut Hill, MA

Abstract: Previous evidence has suggested that true memories can activate early sensory cortical processing regions to a greater degree than false memories, while both true memories and false memories can activate later sensory cortical processing regions. However, such evidence is very limited and, to our knowledge, this pattern of sensory cortical activation has only been reported at the modality-specific (visual/non-detailed) level of processing. The present functional magnetic resonance imaging (fMRI) study was conducted to assess whether similar results would also be observed during memory for feature-specific (motion) information. During the encoding phase, moving or stationary abstract shapes were presented to the left or right of fixation. During the retrieval phase, shapes from encoding were presented at fixation and participants classified each item as previously "moving" or "stationary" within the "left" or "right" visual field. A random effect general linear model analysis was conducted, collapsed over spatial location (as it

has been shown that memory for motion in either hemifield activates MT+ bilaterally). Motion processing region MT+, within the ascending limb of the inferior temporal sulcus, was localized by contrasting moving versus stationary items at encoding (encoding-moving > encoding-stationary). True memory for motion was isolated by contrasting accurate memory for moving items versus inaccurate memory for moving items (moving-hits > moving-misses). False memory for motion was isolated by contrasting inaccurate memory for stationary items versus accurate memory for stationary items (stationary-misses > stationary-hits). Critically, both of the retrieval contrasts corresponded to the subjective experience of "moving" versus "stationary". Furthermore, item type was constant for each retrieval contrast, which avoided stimulus confounds. Similar to previous findings, true memory for motion activated MT+ but false memory for motion did not activate this region (even at a lenient statistical threshold), and both true memory for motion and false memory for motion activated more anterior temporal regions. These results bolster previous findings that have suggested true memory can activate early sensory cortical processing regions to a greater degree than false memory, while both true memory and false memory can activate later sensory cortical processing regions. Moreover, the present results extend previous work as sensory cortical activation associated with true memory reflected feature-specific (detailed) processing.

Title: Age-related differences in the prefronto-parietal and hippocampal network during correct rejections of new items

Authors: *T. TSUKIURA[1], Y. SHIGEMUNE[1], R. NOUCHI[2,3], T. KAMBARA[3,4], R. KAWASHIMA[2]
[1]Cognitive and Behavioral Sci., Grad. Sch. of Human and Envrn. Studies, Kyoto Univ., Kyoto, Japan; [2]Smart Ageing Intl. Res. Ctr., IDAC, Tohoku Univ., Sendai, Japan; [3]Japan Society for the Promotion of Sci., Tokyo, Japan; [4]Fac. of Envrn. and Information Studies, Keio Univ., Fujisawa, Japan

Abstract: Older adults are more likely than young adults to show age-related declines in correctly rejecting events that never occurred (correct rejections) as well as in remembering events that were experienced (hits). Although previous functional neuroimaging studies have often demonstrated the aging effects on neural activations during the successful retrieval of events that happened in the past, little is known how the neural mechanisms related to the correct rejections are affected by healthy aging. The current fMRI study investigated age-related differences in activations during correctly rejecting new items. During encoding, young (23 females; mean age=21.8) and older adults (23 females; mean age=66.1) were presented with unfamiliar faces one by one, and rated the trustworthiness of impression for each face. No reference was made to a subsequent memory test, and therefore encoding was incidental. During retrieval, the participants were presented with old and new faces, and performed a surprising old/new recognition test with confidence ratings (high or low). The fMRI analyses in this study focused only on data during the retrieval of new faces. Activity associated with the correct rejection (CRA) was identified by comparing activities between high- and low-confidence correct rejections for new faces, and the CRAs were compared between young and older adults. Three main findings emerged from this study. First, in behavioral data, older adults than young adults showed higher false alarm rates, but the elevated false alarms in older adults were observed only in high-confidence responses. Second, CRAs in the inferior frontal gyrus (IFG), supramarginal gyrus (SMG), and hippocampus (HIP) was greater in young adults than in older adults. Third, correlations, which were computed by data of individual trials in each subgroup, between IFG, SMG and HIP were significantly higher in young adults than in older adults. These findings suggest that the age-related increase of false alarms could be caused by a lower interaction between the prefonto-parietal region and hippocampal region.

Inst. of Disaster Science, Tohoku Univ., Sendai, Japan; [7]Dept. of Functional Brain Imaging, I.D.A.C., Tohoku Univ., Sendai, Japan

Abstract: Emotion is known to enhance human memory functions. Experiences which are undergone in an emotional situation are remembered more distinctly than those in neutral situations. Although the beneficial effects of emotion on remembering memories have often been identified in the explicit retrieval, little is known about memory enhancement during implicit retrieval. In addition, evidence of the neural mechanisms during implicit retrieval of memories encoded in the emotional context is still unavailable. The current fMRI study investigated the neural mechanisms underlying the implicit retrieval of memory items encoded in an emotional context. In this study, we employed the masked priming method during encoding and the implicit retrieval method during retrieval. These methods are often used to create an implicit memory situation. For the encoding procedures outside the scanner, line-drawn pictures were presented as targets on emotional or neutral backgrounds which were chosen from IAPS. The presentation time of the targets was 12 ms. Presentation was preceded and followed by 40 ms masks so that, participants could not explicitly recognize the target pictures (the masked priming method). During retrieval in the fMRI scanner, previously learned and new line-drawn pictures were encoded one by one in a fragmented form. Participants were required to judge the semantic categories (animal, tool, and other) of the pictures (the implicit retrieval). Behavioral data showed that response times for judging categories of pictures encoded on emotional backgrounds were longer than those of pictures encoded on emotionally neutral backgrounds. fMRI data yielded two main findings. First, the right dorsolateral prefrontal cortex (DLPFC) showed greater activity during judging the category judgment of pictures encoded on negative backgrounds than of those on positive or neutral backgrounds. Based on our behavioral data, which showed the suppression of pictures encoded on negative backgrounds, the activation of the DLPFC would be related to the emotional regulation. Second, activity in the left anterior parahippocampal gyrus (APHG) was greater during the category judgment of old pictures than during that of new pictures. Taken together with previous findings, activity in the DLPFC could be associated with emotional regulation and activity in the APHG could be involved in the automatic processing of oldness for memory items.

(Neurology), Univ. of Toronto, Toronto, ON, Canada

Abstract: Remembering autobiographical events can be associated with detailed visual imagery. The hippocampus, precuneus and prefrontal cortex are held to jointly enable such vivid retrieval, but how these regions are orchestrated with each other remains unclear. An influential prediction from animal physiology is that neural oscillations in the theta range may be important. In this experiment, participants prospectively collected audio recordings of personal events over 2 to 7 months. These were later replayed as autobiographical memory cues while recording brain activity with magnetoencephalography (MEG). General knowledge retrieval served as a control condition. We observed increased theta power in the left hippocampus during autobiographic retrieval. This hippocampal region was selectively phase-synchronized with theta oscillations in precuneus and ventro-medial prefrontal cortex. The strength of hippocampal-precuneus synchrony predicted the amount of visual imagery during retrieval. Thus, theta phase-synchrony orchestrates the hippocampus with the neocortical components of a distributed memory network when remembering autobiographic experiences.

Title: Expectation and evidence as two components of the frontoparietal recognition memory response.

Authors: *A. R. O'CONNOR
Sch. of Psychology, Univ. of St Andrews, St Andrews, United Kingdom

Abstract: A frontoparietal network of regions is recruited when we detect a stimulus whose mnemonic status contradicts its anticipated status (e.g. the presence of an ‘old’ item when a ‘new’ item was expected). Computer-generated ‘hints’ (e.g. “likely old”) can be used to generate mnemonic expectations on a trial-by-trial basis and allow the effects of different hints on the expectation violation response to be characterised. In an fMRI experiment with 18 cognitively healthy participants, I show that the strength of this frontoparietal expectancy violation response is influenced by two components of the hint-stimulus pairing: (1) the salience of the hint; and (2) the degree to which the mnemonic status of the stimulus contradicts its hinted status. More specifically, varying the wording of the hint alters the salience and behavioural consequences of the same hint e.g. “likely old” (high-salience ‘old’ expectation) vs. “unlikely new” (low-salience ‘old’ expectation). The magnitude of neural response to expectation violation reflects the salience of the initial hint, with high salience hints leading to a greater frontoparietal response when they are opposed by recovered memory evidence. High confidence in memory evidence (or lack thereof) is also associated with a comparable expectation violation response in both ‘old’ and ‘new’ items. This suggests the potential for dissociable contributors to the expectation violation response driven by an interaction between the hint and the participant’s confidence in their memory judgement. This interaction does not appear to be dependent on the status of the stimulus itself - ‘old’ items do not lead to a larger frontoparietal recognition response when expectation and confidence are accounted for. These findings suggest that the ‘oldness’ of a stimulus may be less influential on activation in the neural correlates of recognition memory than was previously thought.

Title: Two-population model for medial temporal lobe neurons

Authors: A. MAGYAR, *J. COLLINS
Penn State Univ., UNIVERSITY PK, PA

Abstract: Recordings in the human MTL (Quian Quiroga et al. Nature 435, 1102 (2005) and many subsequent papers) have found many neurons that within the limits of the measurements respond to pictures of just one particular person out of around 100. How selective are these neurons in reality? Direct measurements would require too many stimuli. We present the results of a new method, which gives a more sensitive measure of the selectivity of the responses. The method exploits the large number of sampled neurons, and can determine the response sparsity even when it is much less than one response for the number of presented stimuli.
A previous analysis (e.g., Waydo et al., J. Neurosci. 26, 10232 (2008)) assumed a single neural population with a single response sparsity. We find that such a model gives an extremely poor fit to the data. Instead we propose to use two (or more) populations; one motivation is data from the HVC area of zebra finches, where three populations are distinguished anatomically and have dramatically different firing characteristics during song production.
We analyze the data of Mormann et al. J. Neurosci. 28, 8865 (2008), which give the numbers of neurons responding to different numbers of distinct pictures. We find that two populations give an excellent fit to data from the hippocampus and entorhinal cortex; a more complicated situation occurs for the functionally different amygdala and parahippocampal cortex. The two populations are dramatically different: In the hippocampus, one population has 7% of the cells with a 2.5% sparsity. But a much larger fraction 93% respond ultra sparsely to only 0.1% of the stimuli. This results in an extreme bias in analysis of neural responsiveness.

Title: Patterns of cortical theta during autobiographical and semantic memory probed with magnetoencephalography.

Authors: *E. KAESTNER[1], B. Q. ROSEN[1], S. STEINVORTH[2], S. KOVACEVIC[1], K. MARINKOVIC[1], H. POIZNER[1], E. HALGREN[1]
[1]UCSD, San Diego, CA; [2]Boston Univ., Boston, MA

Abstract: Autobiographical memory (AM) and semantic memory (SM) are both supported by widely distributed brain networks. Studies have implicated theta activity in organizing these networks during encoding and retrieval, but studies of theta in humans during autobiographical memory are lacking. This study estimated the time-course of theta activity across the cortical surface during the retrieval and reminiscence of AM and SM. Since education is taking an episodic instance of learning and turning it into semantic memory, study of the episodic/semantic intersection has implications for learning.
Task stimuli were sentences displayed one word at a time, terminating in a cue to respond with a remember/not button press. The initial words of each sentence allowed the participant to identify the question as autobiographical or semantic. After the button press, participants reminisced on the memory for 6s. To ensure that the participants did not re-encode their memories before the test, AMs were obtained by interviewing their family/friends. Semantic memories were well known objects that are not often currently displayed in the media. Whole-head MEG signals were decomposed for each trial with Morlet wavelets in the theta (4-7 Hz) range. For theta source localization, each subject's cortical surface was reconstructed from their structural MRI which was used to constrain noise-normalized minimum norm estimates.
Reaction times were consistent between AM and SM. The distribution of cortical theta observed was broadly consistent with previous findings from fMRI of AM and SM (NeuroImage, 2006). Further, AM and SM evoked significantly different patterns of theta power. During presentation of the initial words, SM evoked significantly more theta than AM in the precuneus. In contrast, in the 1000ms before the remember/don't button press, successful AMs had greater response locked theta power relative to successfully recalled SMs in the left medial temporal lobe and left orbitofrontal cortex.
fMRI studies suggest that the precuneus is involved in tasks when participants visualize what they remember. The early theta activity suggests that from information in the initial words the brain begins retrieving semantic but not autobiographical memories. Fronto-temporal activation during AM is consistent with lesion and neuroimaging studies. Overall, the current study adds to emerging data supporting a central role of theta activity in the large-scale organization of cortical activity during memory retrieval, and further suggests that theta may contribute to both AM and SM but in different cortical locations and time-periods.

Title: Separating signals in medial prefrontal cortex during episodic simulation using a catch-trial design

Authors: A. W. GILMORE[1], S. M. NELSON[2], *K. MCDERMOTT[1]
[1]Psychology, Washington Univ. In St Louis, St Louis, MO; [2]Psychology, Washington Univ. in St Louis, St Louis, MO

Abstract: A robust observation in cognitive neuroscience is the finding that a distributed set of brain regions tends to be more active during periods of rest than during task performance. This default mode network (DMN) was originally discovered using PET (Shulman et al., 1997) and has since been verified in task-evoked fMRI studies and in resting-state functional connectivity analyses. Despite the initial characterization through task-induced deactivation, recent work has shown many default regions can demonstrate task-related increases in BOLD activity when one's attention is focused internally. In addition, while previous work has often treated the DMN as a generally homogeneous system, studies have now shown dissociations in activity across these regions. For example, Sestieri and colleagues (2011) recently demonstrated task-related deactivations in medial prefrontal cortex (mPFC) during a memory search task, while simultaneously showing task-related increases in posterior DMN regions. Such task-induced dissociation might allow for a deeper understanding of the role of discrete regions within the DMN. The present study sought to further investigate the activity of regions in mPFC during episodic simulation tasks using fMRI. Subjects were asked to recall events from their own personal pasts, envision events that might occur in their own futures, or imagine President Barack Obama participating in various events. By incorporating a catch-trial design (Ollinger et al., 2001), we were able to separately model BOLD activity associated with orienting toward one of these tasks (e.g., preparing to remember) and activity associated with event generation per se (e.g., remembering oneself at a barbecue). We hypothesized that separating the orientation component would provide a clearer picture of mPFC activity when engaging in the simulation task. We found that orientation cues led to significant task-induced deactivation in ventral mPFC regions, whereas the episodic simulation component showed significant positive activation in these same regions. Multiple, temporally overlapping processes may be supported in mPFC; by

separating different components of trials, one can better characterize the contributions of these regions to task performance.

Title: The dynamics of frontoparietal and medial temporal lobe networks during self-initiated memory search

Authors: *J. KRAGEL, S. M. POLYN
Vanderbilt Univ., Nashville, TN

Abstract: In studies of source memory and recognition memory, a probe is presented to the participant, which facilitates time-locked statistical analyses of the brain networks involved in memory retrieval. Such studies have implicated lateral prefrontal cortex, hippocampus, and posterior parahippocampal gyrus in the recovery of contextual details associated with a previously studied probe. However, much less is known about the brain networks engaged during self-initiated memory search tasks such as free recall, where the timing and order of recall responses are variable and determined by the participant. This unconstrained nature of free recall complicates construction of an a-priori model of the cognitive processes underlying any given period of memory search. We collected functional magnetic resonance imaging (fMRI) data while 20 healthy, right-handed subjects (12 female) performed an immediate free-recall task. Independent component analysis was used to identify spatially distinct, temporally coherent networks within the collected data. To determine which networks contribute to recall, two regressors were constructed. A transient regressor was constructed to model activity to individual recall onsets, and a sustained regressor modeled activity maintained throughout the recall period. After rejecting artifactual components based on correlation to grey matter as well as spatial entropy, multiple regression provided a means to relate each component time series to the predicted response. Four transient components were detected, including a frontoparietal network, a cerebellar network, a premotor network, and an insula/temporal lobe network. One sustained component was found, a medial temporal lobe (MTL) network. Chronometric analysis of component time series revealed a cascade of activity, relative to the onset of individual recalls,

with both the frontoparietal and cerebellar components leading MTL and premotor activity. Testing the relationship between activity in these networks and task performance, the amplitude of the MTL component correlated with overall recall performance, while activity in frontoparietal cortex during recall was negatively correlated with recall performance, across subjects. Activity in the MTL network may reflect the retrieval of contextual information that is used to guide memory search in the absence of an external cue. Increased activity in the frontoparietal network may reflect increased control processes that are engaged to compensate for unsuccessful retrieval. These findings demonstrate how ICA can be used to gain leverage on the dynamics of distributed brain networks during self-initiated memory search.

Title: Strategic influences on memory expression: Effects of countermeasures and memory strength on the neural decoding of past experience

Authors: *M. R. UNCAPHER[1], T. CHOW[1], J. RISSMAN[3], J. EBERHARDT[1], A. D. WAGNER[1,2]
[1]Dept Psychol, Stanford Univ., STANFORD, CA; [2]Neurosciences Program, Stanford Univ., Stanford, CA; [3]Dept Psychol, Dept of Psychiatry and Biobehavioral Sci., Univ. of California Los Angeles, Los Angeles, CA

Abstract: Using fMRI and multivoxel pattern analyses (MVPA), we recently demonstrated that individual memories can be detected from distributed patterns of brain activity (Rissman et al., 2010). At the same time, a rich literature indicates that strategic processes at retrieval can impact the neural responses elicited by cues, raising the possibility that people might be able to willfully manipulate their brain responses when motivated to conceal or feign recognition of a given stimulus. To examine how retrieval strategies alter memory-related neural patterns, we investigated (a) whether MVPA decoding of memory states is affected by strategic efforts to conceal memory (i.e., countermeasures), and (b) how the effects of countermeasure strategies interact with memory strength. Following the study of a large set of photographs of faces (Day 1), participants underwent two fMRI retrieval phases (Day 2). During the first retrieval phase,

participants made ‘old/new’ recognition decisions about studied and novel faces. During the second retrieval phase, participants were instructed on how to employ countermeasures that might mask their true memory states. Specifically, for a recognized face, they were instructed to immediately disengage from attending to their memory for that face, instead attending to the surface qualities of the photograph. For an unrecognized face, they were instructed to think of a person that face reminded them of and recollect past experiences with that person. From the ‘old/new’ retrieval data, MVPA classification of correctly recognized old faces vs. correctly rejected new faces was well above chance. By contrast, classifier performance dropped to chance levels when tested on the data from the countermeasures retrieval phase. Moreover, the ability to strategically regulate one’s memory patterns (as assessed by classification performance on the countermeasure data) interacted with memory performance, as evidenced by a significant positive correlation between d’ during the old/new retrieval test and classifier performance during the countermeasures phase. Collectively, these findings demonstrate that relatively simple countermeasure retrieval strategies can significantly alter distributed neural signatures of memory retrieval and/or novelty detection. Although these data highlight the possibility that individuals may be capable of effectively concealing their memory states, participants’ ability to do so was diminished when they had stronger memories for the probed stimulus materials. Thus, the ability to strategically regulate memory-related neural patterns partly depends on the strength of to-be-regulated memories.

Title: Temporal profiles of episodic reactivation: An MEG study

Authors: *S. M. TUBRIDY[1,2], A. C. HEUSSER[2], L. DAVACHI[2,3]
[1]New York Univ., NEW YORK, NY; [2]Psychology, [3]Ctr. for Neural Sci., New York Univ., New York, NY

Abstract: The ability to bind, store, and retrieve complex multi-modal associations is a critical feature of human memory. This ability requires mechanisms by which the brain can link information processed in distinct, non-overlapping cortical. A common element of many theories of hippocampal function is the bidirectional flow of information between distributed cortical regions and the hippocampus. Although details of the theories differ, the basic framework adopted by much of the cognitive neuroscientific community holds that during an experience, distributed patterns of cortical activity are projected into the hippocampus via the medial temporal lobe (MTL) resulting in the formation of a hippocampal representation of elements of an episode. Recurrent connections between hippocampal neurons enable the reinstatement of the hippocampal ensemble given a partial input leading in turn, via backprojections through the MTL, to reactivation of cortical regions in which the contents of the memory are processed. Although empirical work provides support for pieces of the framework, there is currently no direct systems-level evidence demonstrating a temporal profile of hippocampus/MTL memory responses preceding content-specific cortical responses. Here, we leverage the millisecond resolution of Magnetoencephalography (MEG), coupled with emerging techniques for source localization, to assess the temporal relationship between medial temporal lobe signals and reactivation of cortical regions during associative retrieval. During MEG recording participants learn and are tested on a series of word-picture and word-sound associations. During retrieval trials, participants are presented with a word and asked to report the modality of its' associate. Behavioral results indicate successful memory formation, with performance well above chance on retrieval trials. MEG data identifies expected differences during encoding of sound relative to picture associations. Differences in the signal topography are also observed during retrieval trials for which the presented stimuli (words) are matched but the retrieved association differs (sound or picture), indicative of content-specific activity during associative retrieval. The timing of these cortical signal differences are related to memory signals in the MTL to address predictions of standard models of the hippocampal memory system.

Title: Vividness and the retrieval of recent and remote autobiographical memories: An fMRI investigation.

Authors: *S. SHELDON[1,2], B. LEVINE, PhD[1,2,3]
[1]Rotman Res. Institute, Baycrest Ctr. For Geriatric Care, Toronto, ON, Canada; [2]Psychology, [3]Med. (Neurology), Univ. of Toronto, Toronto, ON, Canada

Abstract: It is well acknowledged that the hippocampus is critical for retrieving autobiographical memories, however there is debate concerning the nature of this hippocampal involvement. Neuroimaging studies have suggested that the hippocampus is involved in both recent and remote autobiographical memory retrieval. Other studies have established that hippocampal contributions to autobiographical recall vary as a function of the quality of retrieval, particularly with how vividly a memory is retrieved. In the present study, we explored the interaction of a memory's age and vividness. We used a prospective collection of recent and remote events via audio diary and selected from this audio recordings that served as retrieval cues in an MRI scanner. Based on in-scanner subjective ratings of re-experiencing, all recent memories were classified as vivid and remote events were classified as either vivid or non-vivid. Using Partial Least Square (PLS) to analyze our results, three key findings emerged. First, a common network of brain regions that included the hippocampus was active for memories from both recent and remote time periods. Second, distinct spatial and temporal patterns of neural activity were found for vivid and non-vivid memories. Vivid memories preferentially recruited right frontal, left insular and bilateral posterior and thalamic regions, with this activity peaking early after stimuli onset. Less vivid memories recruited the left cingulate gyrus, right middle frontal gyrus, right temporal gyrus and the thalamus, with peak activation much later in retrieval. These temporal effects were also seen in a hippocampal ROI. Finally, the hippocampus showed different patterns of connectivity for vivid and non-vivid memories. Altogether these findings suggest that quality of retrieval (i.e. vividness) influences the regions involved in autobiographical retrieval, irrespective of a memory's age. The later onset of activity for less vivid memories may reflect that more effort is needed to recover these memories.

Title: EEG effects in the cognitive control of memory using an auditory directed forgetting task.

Authors: *M. E. CANO[1,2], R. T. KNIGHT[2,1]
[1]Helen Wills Neurosci. Inst., [2]Dept. of Psychology, Univ. of California, Berkeley, Berkeley, CA

Abstract: The neural basis of directed forgetting is receiving increased attention, with a particular focus on the role of prefrontal cortex in memory suppression. Most research has focused on visual forgetting. To assess whether directed forgetting extends across sensory modalities we examined whether similar electrophysiological findings, as reported in visual electroencephalography (EEG) studies of directed forgetting, would be observed in the auditory domain. To address this issue, we recorded EEG in a modified auditory version of the Think/No-Think paradigm in young adults. Participants were instructed to first learn auditorily presented word pairs. Successful initial learning was followed by a recall test to confirm sufficient learning. In the next phase of the experiment, participants were again presented with the first word of each pair, accompanied by a visual instruction cue consisting of a red or green box indicating to either silently retrieve the second word of the pair (green box) or to inhibit recollection of the second word of the pair (red box). Subsequent memory was later tested with a same-probe and an independent-probe memory test to determine the effect of instruction and active control of memory on later memory. Here, we examine task-related EEG activity during covert intentional memory retrieval. Event-related potentials (ERP) revealed two main memory manipulation effects: No-think trials elicited an early frontal amplitude positivity decrease (200 to 300 ms) and a sustained late parietal amplitude increase (600 to 1000 ms) compared to Think trials. This ERP pattern is similar to that reported in visual studies and supports a modality non-specific mechanism for directed forgetting. The EEG data also provides evidence supporting differing roles and time courses of prefrontal and parietal cortices in the flexible control of auditory memory.

Title: ERP correlates of recognition without identification across real-world visual stimuli

Authors: *S. R. STALEY[1], A. J. RYALS[2], S. J. LEONARD[2], M. J. COWEN[2], W. J. MAHER[2], T. J. HAWKINS[2], A. M. CLEARY[2]
[2]Psychology, [1]Colorado State Univ., Fort Collins, CO

Abstract: Recognition without identification (RWI) is observed when one is able to recognize an object as familiar despite an inability to retrieve the identity of the object. Traditionally, RWI has been studied in the laboratory using list-learning paradigms, showing that participants can discriminate studied from unstudied items among those that fail to be identified. Work from our laboratory suggests that the RWI effect can be applied to real-world stimuli as well. Participants are able to discriminate through familiarity ratings between famous and non-famous faces, famous and non-famous scenes, and living threats vs. non-threats in color photographs filtered with a monochromatic noise filter even when they are unable to identify the stimuli. The literature points toward various potential ERP components correlating with this effect. The N170 shows face sensitivity and may involve structural coding specific to faces, and the N300 has been previously implicated in at least one type of list-learning RWI effect, displaying differences for items which participants are able to correctly identify as having been previously studied. The present study examined the electrophysiological correlates of the real-world-stimulus RWI effect with faces and scenes. In two experiments, participants judged photographs that had been filtered by a monochromatic noise filter while high-density EEG was being recorded. Experiment 1 consisted of filtered famous and non-famous faces, and Experiment 2 consisted of filtered famous and non-famous scenes. Participants rated familiarity and attempted to identify the face or scene for each filtered photograph. A final phase of each experiment consisted of presentation of the famous faces or scenes unfiltered in order to determine whether the subject would have known the famous face or scene had perception not been hindered through masking. A behavioral RWI effect was observed in both types of stimuli by which familiarity ratings were higher for filtered famous photographs that were later identified than for the filtered non-famous photographs. Electrophysiological recordings revealed higher negativity at 140-190 ms, consistent with the N170, for unidentified filtered non-famous faces than for unidentified filtered famous faces that were later identified when unfiltered. In addition, an N300 component was observed whereby filtered famous scenes that were later identified when unfiltered evoked a higher negativity at 250-350 ms than did non-famous scenes. These findings implicate early processing of familiarity even before conscious recognition of the stimuli.

Title: Low-frequency ECoG phase synchronization couples medial temporal lobe and neocortical activity during spatial and temporal human source memory retrieval

Authors: A. WATROUS[1], *N. TANDON[2], C. R. CONNER[3], T. A. PIETERS[3], T. ELLMORE[3], A. EKSTROM[1]
[1]UC Davis, Davis, CA; [2]Neurolog. Surgery, Univ. Texas Med. Sch., HOUSTON, TX; [3]UT Houston, Houston, TX

Abstract: Episodic memory, remembering the when and where of prior experience, is primarily dependent on the medial temporal lobes (MTL), with frontal and parietal networks playing additional roles in this process. The exact contribution of these regions and their inter-regional interactions during spatiotemporal retrieval, though, remains unclear. To address this issue, patients performed a task in which they retrieved spatial and temporal details associated with an episode while we recorded intracranial EEG simultaneously at multiple lobular sites in the frontal, parietal, and medial temporal lobes. Results showed significant increases in low-frequency phase synchronization in the MTL-Frontal, MTL-Parietal, and Frontal-Parietal networks during correct versus incorrect episodic retrieval. The MTL acted a convergence hub for all aspects of episodic memory processing, with prefrontal-MTL interactions playing additional roles in spatiotemporal representation and subregions of parietal cortex (precuneus and inferior parietal cortex, respectively) playing more selective roles in aspects of spatial and temporal processing. Further, the spatial and temporal retrieval networks were dissociable based upon the frequency and timing of their network interactions. The spatial network was characterized by interactions in the delta band that occurred earlier in time compared to the temporal retrieval network, which showed interactions primarily in the theta band. These results emphasize the importance of dynamic network interactions as central to episodic memory retrieval, and demonstrate dissociated networks for the retrieval of spatial and temporal aspects of an experience.

Title: Memory binding in hippocampus predicts successful associative memory in children

Authors: *K. WURMITZER[1], D. VON ALLMEN[2], E. MARTIN[2], P. KLAVER[2,3,4]
[1]Universitaets-Kinderkliniken Zurich / Mr-Zentrum, Zürich, Switzerland; [2]Universitaets-Kinderkliniken, Zurich, Switzerland; [3]Inst. of Psychology, Zurich, Switzerland; [4]Zurich Ctr. for Integrative Human Physiol., Zurich, Switzerland

Abstract: Behavioural evidence suggests that the ability to use strategies in episodic memory (EM) develops from childhood through adulthood [1, 2]. In opposite to the protracted development of strategic memory functions, associative memory is used efficiently in early development [3]. Children's ability in building associations is beneficial for memory performance and reflects the involvement of binding processes that may become less proficient in adults [4, 5]. However, it is currently unknown which neural mechanisms support children's superior associative memory performance. It is well accepted that MTL structures are involved in single item and associative item recognition [6, 7, 8] but their roles during development are less clear. Piecing these notions together we tested 16 healthy adults (19-26 years) and 5 children (7-12 years) using a subsequent associative memory paradigm. After the study phase in which participants incidentally learned pairs of objects, EM recognition was tested inside the MR-scanner. A subsequent associative memory task followed in which they indicated the correct pair item to a target item. First data on memory performance data showed that children retrieved more correct pairs than adults (children: M=.51, SD= .07; adults: M=.38, SD= .11; T_{19}= 2.53, p=.021). Preliminary fMRI data revealed a significant activation within the right hippocampus (hc; local maximum at [39, -28, -11], z= 3.36, p<.05, unc.) and left hc (local maximum at [-39, -31, -8], z=3.43, p<.05, unc.) for correctly identified associative hits in children compared to adults. Additionally the adult group showed increased activity within the left MTL (local maximum at [-33 -22 -20], z=3.77, p<.001, unc.) and left intraparietal sulcus (IPS; local maximum at [-33 -52 40], z=4.28, p<.001, unc.), whereas children showed lower activation in parietal areas. These data provide evidence that mainly the hc is related to successful associative memory in children and contributes to outperformance in associative memory compared with adults. In addition we suggest that adults rely more on the use of attention driven memory retrieval associated with activity in the posterior parietal cortex. In the future we will examine

more children to get robust effects of memory processing in children.

Title: Is recollection-related activity in left lateral parietal cortex sensitive to the salience of the retrieved information?

Authors: *R. ELWARD[1,2], K. L. VILBERG[1,2], M. D. RUGG[1,2]
[1]Ctr. For Vital Longevity, Dallas, TX; [2]Behavioral and Brain Sci., Univ. of Texas, Dallas, Dallas, TX

Abstract: Recollection of episodic information is associated with enhanced neural activity in the ventral aspect of left parietal cortex, in the vicinity of the angular gyrus. The functional significance of this finding is a subject of debate. According to one proposal, recollection effects in the angular gyrus reflect the role of this region in supporting the representation or maintenance of recollected information. Alternatively, it has been proposed that the effects reflect the region's role in mediating the 'bottom-up' re-orienting of attention away from the retrieval cue and towards the products of recollection. The present study attempted to adjudicate between these proposals by manipulating the salience of recollected information. According to the representational account of left parietal recollection effects, the salience of the recollected content should not impact the magnitude of the effects. By contrast, the attentional re-orienting account predicts that the effects should co-vary with salience. Subjects studied a series of pictures of objects, each of which was co-presented with a picture of a coin, either a

Deutschmark or a Lira. Crucially, subjects were unaware during study that the coins would be assigned different reward-values prior to the test phase. Test items comprised studied (old) and unstudied (new) objects. The requirement was to discriminate between old and new items and, for any item judged old, to judge whether it had been studied along with a Deutschmark or a Lira. Two dollars were awarded for each correct 'Deutschmark' judgment, whereas only a 2 cent reward was associated with correct Lira judgments. Incorrect judgments were penalized at the same rate as the reward, and no feedback was given during the test. Consistent with numerous prior findings, successful source judgments were associated with enhanced activity in left angular gyrus. These source recollection effects were however unaffected by the reward value of the recollected information. Importantly, effects of reward were evident in other brain regions, including those - such as the nucleus acumbens - classically associated with reward processing. The findings are difficult to reconcile with the proposal that recollection-related activity in the angular gyrus is a reflection of attentional re-orienting, at least as this process is usually conceived.

Title: Dissociating the neural correlates of recollection and maintenance of recollected content using fMRI

Authors: *K. L. VILBERG, M. D. RUGG
Ctr. for Vital Longevity, Sch. of Brain & Behavioral Sci., Univ. of Texas, Dallas, Dallas, TX

Abstract: Prior studies have identified a network of brain regions involved in successful episodic retrieval (recollection). In the present study, we investigated whether these regions could be distinguished according to whether recollection-related activity was transient or sustained across the time that recollected information had to be maintained prior to a behavioral judgment. In experiment 1, subjects studied a series of word-image pairs under the requirement to judge which of the paired objects was smaller. Following each of 4 study sessions, a scanned test phase occurred in which a series of studied and unstudied words was presented. The requirement at test was to decide whether each test item was old or new and, if judged old, to

retrieve the associated study picture and hold it in mind until a question cue appeared. The item-cue interval varied between two and eight seconds. The cue instructed subjects which of three different judgments should be applied to the retrieved picture (bigger than a shoebox? household object? living?). Separate responses were required when test items were either deemed new or the associated picture could not be retrieved. fMRI data were modeled to separately estimate activity elicited by the test items (transient effects) as opposed to activity sustained over the item-cue interval ('delay activity'). Regions demonstrating transient recollection effects were identified in the retrosplenial cortex and left parahippocampal/fusiform cortex extending into the hippocampus. Sustained effects were identified in left posterior parietal cortex extending into the angular gyrus, the left inferior temporal cortex, and lateral and medial prefrontal cortex, among other regions. Experiment 2 was identical to the prior experiment except that pictures instead of words were employed as test items, and the cues presented at the end of the item-cue interval queried different properties of the retrieved word (number of 'E's, number of syllables, whether the first and last letters were in alphabetic order). Similarly to experiment 1, sustained recollection effects were identified in a fronto-parietal network that included the left angular gyrus, intraparietal sulcus, and inferior temporal cortex, while transient effects were identified in the posterior cingulate/retrosplenial cortex and left medial temporal cortex. Thus, independently of its content, maintenance of recollected information engages a characteristic network of brain regions. It is hypothesized that some of these regions, including the angular gyrus, contribute to the 'episodic buffer' proposed to mediate between episodic memory and executive processes.

Title: Electrocorticography-constrained evaluation of the arcuate fasciculus

Authors: *E. C. BROWN, J.-W. JEONG, O. MUZIK, R. ROTHERMEL, N. MATSUZAKI, C. JUHASZ, A. K. SHAH, S. MITTAL, S. SOOD, E. ASANO

Abstract: Over a century after the Wernicke-Lichtheim model, language connectivity has focused on a link between Wernicke's region and Broca's area via the arcuate fasciculus (AF). However, no detailed anatomical study has yielded solid evidence that AF terminates within Broca's area. The inferior lateral precentral gyrus (ILPreC) has been proposed as an alternative AF termination. Using diffusion tensor imaging (DTI) tractography, we determined the anterior termination of AF in healthy individuals. We subsequently determined whether temporal language sites defined by electrocorticography (ECoG) in epilepsy patients show white matter connectivity favoring Broca's area or ILPreC as a termination.

We studied five focal epilepsy patients who underwent ECoG prior to resective surgery and eight healthy control subjects (age 9-26). All subjects received imaging including 55-direction DTI. Patients received an auditory naming task during ECoG to determine language sites. Landmark-based conformal cortical mapping of individuals to an MNI152 atlas brain was performed. Atlas-based seed (S) and target (T) regions were defined: S1 - posterior half of superior temporal gyrus (STG), S2 - posterior half of middle and inferior temporal gyri (MTG/ITG), T1 - posterior two thirds of inferior frontal gyrus (Broca), T2 - ILPreC, and T3 - inferior lateral postcentral gyrus (ILPostC). Probabilistic tractography used atlas-defined seeds in controls. In patients, seeds were defined as superficial white matter within 8mm of a temporal lobe ECoG electrode showing significant language-related gamma activity. Percentage of total fibers tracking to each target was determined.

Across controls, tracking from STG revealed ILPreC to be a more likely termination than ILPostC but not Broca ($p = 0.030$ by Friedman's ANOVA - median of ILPreC vs. ILPostC: 0.0065% to 0%, $p = 0.028$ by Wilcoxon Signed Ranks). ILPreC was the primary termination from MTG/ITG ($p = 0.017$ by Friedman - ILPreC vs. Broca: 0.3389% to 0.0023%, $p = 0.017$; ILPreC vs. ILPostC: 0.3389% to 0.0025%, $p = 0.018$). Across 41 language-related temporal ECoG electrodes, 14 associated with tractography fibers to the targets. Across these 14 sites, the ILPreC was the primary termination ($p < 0.001$ by Friedman - ILPreC vs. Broca: 0.097% to 0.0079%, $p = 0.001$; ILPreC vs. ILPostC: 0.097% to 0%, $p = 0.001$). In no case was connectivity to Broca different from that to ILPostC.

This is the first study to constrain tractography with language-related ECoG. We found the primary termination of AF to be the inferior lateral precentral gyrus. We failed to show preferential connectivity between canonical language sites of temporal and frontal areas in our small cohort.

Sch. of Med., Kyoto, Japan; [5]Dept. of Cognitive Psychol. in Edu., Kyoto Univ. Grad. Sch. of Edu., Kyoto, Japan

Abstract: **Introduction**: The role of the ventrolateral part of the anterior temporal lobe (vATL) varies across disciplines, ranging from language function (known as basal temporal language area) to higher-order visual cognition. These mixed ideas can be accommodated by an idea of the ATL as being crucial for pan-modal semantic processing. Recent neuropsychological (semantic dementia patients), neuroimaging, rTMS studies are consistent with this idea. However, the patients' lesion is not confined to this specific area; the fMRI does not demonstrate the necessity of this area; non-invasive rTMS cannot target this specific basal area due to its buried anatomical location. We had a rare opportunity to probe the functioning of this area directly in late-onset partial epileptic patients, whose semantic performance appeared to be normal.
Methods: Subjects are three intractable partial epilepsy patients who underwent invasive presurgical evaluation with subdural electrodes (IRB #C533). High frequency electrical cortical stimulation and recording of local field potential (LFP) during semantic tasks were performed in the left language-dominant temporal lobe. In two patients, additionally, we undertook a systematic assessment of the vATL in comprehension and naming. Electrical cortical stimulation with four levels of intensity [sham, 3, 6, and 9mA] was delivered to the electrodes at the vATL whilst picture naming and written word to picture matching were tested.
Results: The robust LFP was observed maximally in the left anterior fusiform gyrus. Electrical cortical stimulation indicated that this region was involved in pan-modality, semantic processing. The core region identified with these two methods converged at and around the anterior fusiform gyrus across the patients, and was in good concordance with the semantic activation foci in previous neuroimaging studies. In two patients, additional graded electrical stimulation was delivered to the core region. The reaction time became more prolonged in the naming task than in the matching task as the stimulus intensity increased. Severe anomia with semantic/omission errors were also observed. All of these mimicked the typical behavior of semantic dementia patients.

Conclusions: The vATL is crucial for pan-modal semantic cognition both in expressive and receptive tasks and thus could be referred to as the basal temporal "semantic" area.

Title: Link between the dorsal and ventral language pathways in the temporal lobe: A cortico-cortical evoked potential study

Authors: *R. MATSUMOTO[1], T. KUNIEDA[2], A. SHIMOTAKE[1], K. USAMI[1], K. KOBAYASHI[1], H. IMAMURA[1], N. MIKUNI[4], S. MIYAMOTO[2], H. FUKUYAMA[3], R. TAKAHASHI[1], A. IKEDA[1]
[1]Dept. of Neurology, Kyoto Univ. Grad. Sch. of Med., Kyoto, Japan; [2]Dept. of Neurosurg., [3]HBRC, Kyoto Univ. Grad. Sch. of Medicince, Kyoto, Japan; [4]Dept. of Neurosurg., Sapporo Med. Univ., Sapporo, Japan

Abstract: Introduction: Contemporary neuroscience indicates a dual-stream model of speech processing: the anterior, ventral stream from the primary auditory cortex to the anterior temporal lobe for speech comprehension, and the posterior, dorsal stream to the posterior temporal and then to the frontal lobe for auditory-motor integration (Scott & Johnsrude, 2003; Hickok & Poeppel, 2007; Ueno et al., 2011). The link, however, between these two pathways remains elusive. Although limited to invasive presurgical evaluation, cortico-cortical evoked potentials (CCEPs) can trace the connections *in vivo* by directly stimulating a part of the cortices and by recording CCEPs from the adjacent and remote cortices with excellent time and spatial resolution (Matsumoto et al., 2004). We aimed to trace cortico-cortical connections between the dual streams in the temporal lobe, with emphasis on the connections among the anterior temporal language area (ATLA) in the ventral stream, the posterior temporal language area (PTLA) in the dorsal stream, and the basal temporal language area (BTLA) in the ventral anterior temporal

region.
Methods: 9 epilepsy patients who underwent invasive presurgical evaluation with subdural electrodes participated in this study (IRB No.443). After cortical language mapping with 50 Hz electrical stimulation, repetitive electrical pulses (1 Hz) were applied to ATLA, PTLA and BTLA, and CCEPs time locked to the stimuli were recorded from the lateral and basal parts of the language-dominant, left temporal lobe. Stimulus and CCEP response sites were anatomically identified by MRI-electrode coregistration.
Results: Stimulation of PTLA (pSTG & pMTG, 7 patients) elicited remote CCEPs in the ventral stream [aSTG (ATLA, n=2) and aMTG (n=4)] and BTLA (aITG, n=6). Stimulation of ATLA (aSTG, n=4) showed CCEPs in the dorsal stream [pMTG (PTLA, n=2; no function, n=1)], and BTLA (aITG, n=3). BTLA stimulation (aITG or anterior fusiform, n=7) elicited CCEPs in the ventral stream [aSTG (ATLA, n=3; no function, n=1), aMTG (n=5)], and the dorsal stream [pMTG & pSTG (PTLA), n=6].
Conclusion: The present electrical tract-tracing study demonstrated bidirectional connections between ATLA and PTLA that link the dual streams. Both pathways also had access to BTLA in the ventral anterior temporal region presumably for semantic processing.

Title: Single-trial decoding of open class and closed class words using EEG

Authors: *M. S. MELLEM, R. B. FRIEDMAN, A. V. MEDVEDEV
Georgetown Univ., Washington, DC

Abstract: The ability to classify single words based on brain signals has potential applications for neurofeedback and brain-computer interfacing. One classification of importance is that of open class vs. closed class. Open class words (content words) contain semantic content, while closed class words (function words), provide grammatical structure to the sentence. Whether a word is an open or closed class word is particularly important as it signifies the word's role in a sentence. While univariate analysis has provided evidence that the neural correlates of these classes are dissociated (e.g., Neville et al., 1992), it has not yet been determined whether these neural signals can be used for single-trial classification of word class. In this study, we demonstrate single-trial decoding of word class (open v. closed) using multivariate analysis. Nine subjects read sentences while their EEG was recorded. We performed multivariate classification on the ERPs between 200-800ms after the appearance of a word stimulus. After standard preprocessing including artifact removal, we used a binary Support Vector Machine (SVM) classification algorithm and a 5-fold cross-validation method implemented in the Fieldtrip and Donders Machine Learning toolboxes to train the classifiers on the two word classes and to test them on single trials. At chance, classification is 50%, but after training on the SVM classifier, classification averaged 58% correct (and ranged from 55% to 67%) across subjects. When testing individual classification accuracy, we found that it was significantly greater than chance classification (binomial test, $\alpha<0.05$) for 8 of the 9 subjects. Importantly, the features pivotal for classifying the words were concentrated in left frontal channels. This left anterior location is in line with previous univariate results showing a dissociation of word class across these channels. These results not only lend further evidence to the dissociation of words by class but do so with some success on a trial-by-trial level. Additionally, they demonstrate the capability of an EEG classifier to decode building blocks of sentences which may one day lead to real-time decoding of sentences from electrical potentials of the brain.

Title: A cross-modality fMRI investigation of sentence context effects on speech perception

Authors: *S. A. GUEDICHE[1], Y. ZHU[2], D. MINICUCCI[1], S. E. BLUMSTEIN[1]
[1]Cognitive, Linguistic, and Psychological Sci., [2]Neurosci., Brown Univ., Providence, RI

Abstract: Until recently, neuroanatomical models of reading and speech processing have evolved independently despite evidence for interactions between the two systems. Most theoretical models of speech perception are hierarchically organized with increasing levels of abstraction when mapping from acoustic and phonetic processes to higher levels of lexical and semantic processes. While models of reading have suggested several different routes by which orthographic information can access meaning, the details regarding interactions between perceptual and semantic processes across different modalities remain unclear.
Current neuroanatomical models of speech postulate feedforward and feedback interactions along a ventral processing stream between perceptual and semantic processes. In an fMRI study, we examine the neural areas underlying potential interactions between an orthographically presented sentence context and the perception of an acoustically ambiguous target word. To this end, we presented orthographical sentence contexts where we manipulated the Sentence Type (biased, neutral), and then investigated the effects of Sentence Type on an acoustically presented word target where we manipulated the Target Type (ambiguous, unambiguous) (e.g. coat vs. goat).
Behavioral results show a significant effect of sentence context on the categorization of the acoustically ambiguous word target. Preliminary functional neuroimaging results indicate that interactions between Sentence Context and Target Type emerge in anterior superior temporal gyrus bilaterally, and in a right mid superior temporal gyrus area that extended into the parahippocampal gyrus. A correlation analysis on these functionally defined regions revealed connectivity between the mSTG region of interest and parietal and fusiform areas, and between the aSTG region of interest and parahippocampal and occipital areas.
These findings provide support for interactions between neural networks involved in reading and speech perception by showing that the integration of higher-level semantic information presented in the visual modality can influence acoustic speech perception of a subsequent target word. Interactions between Sentence Context and Target Type have also been observed in a previous fMRI study that used acoustically presented sentence contexts in temporal cortex, although the interaction emerged in a more posterior MTG/STG area. These sets of results suggest that while access to meaning and its influence on acoustic speech perception occurs through interactions along a ventral pathway, presentation modality may affect where this interaction takes place.

Title: Anodal transcranial direct current stimulation (tDCS) of primary motor cortex improves word-retrieval

Authors: *M. MEINZER, R. LINDENBERG, M. SIEG, K. AVIRAME, A. FLÖEL
Charite Univ. Med., Berlin, Germany

Abstract: A tight link between linguistic functions and activation of motor areas has been consistently reported in numerous studies indicating that the two systems share functional neural resources (Pulvermüller, 2005, Nat Rev Neurosci). Mutual interactions of these two systems have been demonstrated in healthy subjects (Liuzzi et al., 2011, Curr Biol) and in patients with post-stroke language impairments (aphasia; e.g., Meinzer et al., 2011, Neurorehabil Neural Repair). However, neural correlates of beneficial effects of motor-cortex pre-activation on language functions have not been studied systematically. This issue was addressed in the present study by using functional magnetic resonance imaging (fMRI) and simultaneous non-invasive brain stimulation. In particular, 18 healthy right-handed healthy young subjects performed an overt semantic (category-based) word-generation task during fMRI at 3T. Behavioral and neural effects were assessed in the scanner in a cross-over design during simultaneous excitatory ("anodal") transcranial direct current stimulation (atDCS) or a placebo stimulation condition ("sham") that were both administered over the primary hand motor cortex. Similar to a previous study that found beneficial effects of atDCS administered over a core language region (inferior frontal gyrus, Meinzer et al., 2012, J Neurosci), motor cortex stimulation improved word-retrieval (expressed as a significantly smaller number of errors during the semantic word-generation task). Preliminary analysis of fMRI data suggests that behavioral effects may be mediated by activity modulations in primary motor and language areas (prefrontal and superior/middle temporal cortices). Thus, the positive findings in this proof-of-principle study provide a rationale for exploring the effectiveness of motor cortex stimulation in patients with acquired language disorders (aphasia).

Title: Disentangling speech, spectrum and melody - An fMRI investigation of spectral complexity, intelligibility and intonation profile in the perception of degraded sentences.

Authors: *S. K. SCOTT[1], C. MCGETTIGAN[2], J. KYONG[5], T. HOWE[3], S. ROSEN[4]
[1]Univ. Col. London, London, United Kingdom; [2]ICN, [4]SHAPS, [3]UCL, London, United Kingdom; [5]Dept. of Radiology and Med. Res. Inst., Ewha Womans Univ., Seoul, Korea, Republic of

Abstract: A influential early PET study of speech perception identified a response to intelligible speech in left anterior superior temporal sulcus (STS), while a right-hemisphere homolog was preferentially responsive to sounds conveying a clear sense of pitch (Scott et al., 2000). The present fMRI study expanded the previous design to allow a factorial investigation of the neural correlates of speech intelligibility (vocoded vs. vocoded+spectrally-rotated speech), speech melody (normal vs. flattened) and spectral complexity (2, 4 or 6 vocoded channels). Nineteen healthy adult speakers of English were familiarised with example sentences from all the conditions before entering the scanner, where they listened passively to further examples and attempted to understand as much as possible from the sentences during two functional runs of data acquisition. Replicating the main findings of Scott et al. (2000), the analyses revealed left-dominant responses to increased intelligibility extending from posterior to anterior STS, for both intelligibility resultant from increased spectral complexity (2 < 4 < 6 channels) or a comparison of vocoded vs. rotated conditions. Also similar to the previous work, a right-dominant preference for dynamic pitch profiles was found in the right superior temporal gyrus (STG; all results at voxel height threshold p < .001, cluster correction p < .05). There was no evidence for an interaction between intelligibility and intonation processing, presumably reflecting the fact that intonation is not a dominant cue to lexical identity in English (compared with, for example, tonal languages such as Mandarin). However, nor did any voxels at the chosen threshold show an interaction between speech intelligibility and spectral complexity - that is, a significantly greater effect of increasing complexity for the vocoded conditions (where increased complexity yields greater intelligibility), than for the vocoded+rotated items (where items remain unintelligible regardless of complexity). There was a trend toward this pattern, where the vocoded items showed a more extensive response to increased complexity in left STS than that shown by the rotated items, but the prevailing effect was an overall profile of greater signal for the vocoded than the rotated conditions along the whole STS. We discuss these

findings in the context of hierarchical models of auditory processing and the potential role of top-down / feedback connections in speech comprehension.

Abstract: In human language, learning is a continuous process that require a constant upgrade of our vocabulary even into adult life. Moreover, most individuals aim to learn a new language that also requires the learning of new words. A common observation is that there are large individual differences in language learning, and the neurobiological bases of this variability are unknown. In the present study, we combined Diffusion Tensor Imaging (DTI)-Tractography and functional MRI (fMRI) to study the correlation between anatomical and functional variability of language pathways and their association with interindividual differences in language learning. Twenty-seven right-handed subjects (12 females) were recruited for this study. Language learning consisted in a speech segmentation task (i. e. to segment the speech stream in order to isolate possible words for later memorization) that subjects performed in a 3T scanner while during the fMRI acquisition. Functional connectivity analyses between frontal, temporal and parietal language regions were estimated from functional MRI time series during the learning task. DTI was also acquired and virtual dissections of the three segments of the arcuate

fasciculus performed. Number of streamlines, fractional anisotropy and perpendicular diffusivity were measured for each tract.
Our results showed that microstructural properties of the left direct connections between classical Broca's and Wernicke's areas, as measured by radial diffusivity (RD) and number streamlines (Ns), predicted performances in word learning (RD: Pearson = -0.6; $p < 0.005$) and the strength of the functional connectivity between the activated language areas (Ns: Pearson = 0.45; $p < 0.037$). In addition, the strength of functional connectivity also predicted the word learning performances ($p < 0.036$). In conclusion, this study is the first to demonstrate that our ability to learn new words rely on a efficient and fast cross talk between temporal and frontal areas in the left hemisphere that is related also to their structural connectivity.

Title: Brain basis of chinese character and english word reading in children

Authors: *A. J. KRAFNICK[1,2], L.-H. TAN[3], M. M. LUETJE[1], E. M. NAPOLIELLO[1], G. F. EDEN[1]
[1]Pediatrics, Georgetown Univ., WASHINGTON, DC; [2]Interdisciplinary Program in Neurosci., Washington, DC; [3]Univ. of Hong Kong, Hong Kong, Hong Kong

Abstract: Functional brain imaging studies of reading in adults have shown that the left occipito-temporal cortex, termed the visual word form area (VWFA; Cohen et al., 2002; see also Price and Delvin, 2003) is engaged during reading, independent of whether reading occurs in alphabetic or logographic writing systems (Bolger et al., 2005). The early developmental process that leads to this universal use of the VWFA has not yet been investigated. Here we examine processing of words, characters and objects in monolingual English reading children attending 1st grade in the U.S. and Chinese reading children in Beijing, to establish if the VWFA is observed in both groups of beginning readers.
17 American and 16 Chinese 6 and 7 year olds (matched for reading and non-verbal IQ) underwent three types of runs: English Words, Chinese Characters and Objects and viewed

alternating blocks of these stimuli and Scrambled versions thereof as a visual control. These were interspersed with a resting Fixation baseline condition. Stimuli appeared either just to the right or left of fixation and subjects responded with a button press to indicate which side of fixation cross the stimulus appeared. Scans were obtained on identical 3Tesla Siemens Trio whole-body MRI systems in both locations. Analyses were restricted to bilateral fusiform/inferior temporal gyri (AAL Atlas).
Within-group analyses revealed that relative to Fixation, native learners of English showed bilateral activation for Objects, left hemisphere activation for Words and right hemisphere activation for Characters (p Scrambled Objects, neither group showed activation for their native writing system > Scrambled condition, suggesting specificity to the native writing system has not yet developed. A conjunction analysis between the groups for each group's native writing system ($p<0.001$ uncorrected height threshold) resulted in a significant cluster centered at -42, -56, -12, suggesting that both group were learning to read using the VWFA (relative to Fixation), consistent with the neuronal recycling hypothesis (Dehaene and Cohen, 2007). However, while percent signal change (PSC) within this cluster was similar for all stimuli in the U.S. group, PSC for Chinese Characters was significantly higher than English Words in the Chinese students, indicative of early differentiation for native versus unknown writing systems in this group.

Title: Effects of sensory and signed language experience on the neural basis of visual motion processing

Authors: *T. M. EVANS[1], O. A. OLULADE[1], D. S. KOO[1,2], G. F. EDEN[1]
[1]Georgetown Univ., Washington, DC; [2]Gallaudet Univ., Washington, DC

Abstract: Previous investigations have shown that the neural substrates mediating visual motion processing are altered by sensory experience (i.e. deafness) and/or American Sign Language

(ASL) experience. Specifically, Bavelier *et al*. (2001) found higher percent signal change in posterior parietal cortex and greater extent of activation in posterior superior temporal sulcus in deaf signers compared to both hearing signers and hearing non-signers. Subsequent studies of native signers (Fine *et al*., 2005; Sadato *et al*., 2005) replicated findings in superior temporal cortex, affirming that plasticity can occur with altered sensory experience. However, participants in this research have been native users of sign language and the question arises whether the sensory-induced plasticity would be the same for deaf people who are not native users of sign, which is the case for most deaf individuals (as 90% of deaf people are born to hearing parents). During the acquisition of fMRI data, deaf and hearing subjects performed a visual motion task, indicating the direction (right/left) of motion of coherent dots via button press in a dynamic condition. In a static (control) condition, subjects indicated which side of the screen (right/left) contained a greater density of dots. Single subject maps were generated for the dynamic > static condition, then two-sample t-tests were performed to assess between-group differences ($p < 0.005$ height threshold, FWE corrected $p < 0.05$).

We found significantly greater activation in right superior temporal gyrus (STG) extending into primary auditory cortex in deaf native signers (n=14) compared to hearing native signers (n=16) in accordance with previous findings. However, in deaf adults who were raised with oral or cued English and were not native users of ASL (n=14), we did not replicate this right STG difference and instead found greater left superior parietal lobe activity when compared to a group of hearing participants (n=15).

In the light of previous work demonstrating differences attributed to ASL experience (Bavelier *et al*., 2001) we also directly contrasted our hearing participants with and without signing experience, but revealed no differences. The parallel comparison in our deaf participants (deaf native signers vs. deaf oral/cued English group) however revealed significantly greater activation in right precuneus, precentral gyrus and bilateral cingulate/medial frontal gyri in deaf native signers.

These results indicate that sensory and language-dependent plasticity will differ for deaf individuals depending on their language background and that studies in native users of ASL cannot be generalized to the entire deaf population.

Title: The role of theta oscillations in parsing speech into syllables for speech decoding

Authors: K. B. DOELLING[1], L. H. ARNAL[1], O. GHITZA[2], *D. POEPPEL[1]
[1]Psychology, New York Univ., New York, NY; [2]Biomed. Engin., Boston Univ., Boston, MA

Abstract: We investigate how the human brain parses speech signals into chunks of the appropriate temporal granularity to facilitate decoding of spoken language (Ghitza, 2011; Giraud and Poeppel, 2012). One hypothesis suggests delta-theta (3-8 Hz) oscillations in auditory cortex extract low frequency temporal cues in the auditory input, aiding in the process of parsing speech into roughly syllable-size representations.
To test this hypothesis, Ghitza (2012) measured intelligibility of speech signals with manipulated modulation spectra. Three manipulations are relevant to our study. In a "Stop" condition, the envelopes of each critical band of the stimuli (7-digit strings) were filtered with a stop band from 2-9 Hz, removing spectro-temporal information in the theta band range and removing low frequency temporal cues in the speech waveform. To assess the importance of such cues, in a "Peak Position Coding" (PPC) condition, each critical band signal was replaced by short (50 ms) band-limited noise bursts of uniform shape and amplitude which were placed at the peaks in each critical band's envelope, creating an artificial input rhythm derived from these temporal cues. In the "Stop&PPC" condition, the Stop and corresponding PPC stimuli were linearly summed. Thus, we deprive the theta oscillation of an input rhythm to track (Stop), artificially create one (PPC) and then sum these together (Stop&PPC) to aid theta oscillations in tracking the envelope of this extremely degraded stimulus. Our participants listened to these altered speech sounds and rated their intelligibility while undergoing MEG recording.
Consistent with Ghitza's (2012) findings, intelligibility of the Stop&PPC condition was significantly higher than both the Stop and PPC cases. Intertrial phase coherence analyses of the neural recordings (Luo & Poeppel, 2007) suggest that the ability of the auditory theta oscillation to track low-frequency transients in speech is impeded in the Stop condition, but is regained in the Stop&PPC condition. Remarkably, this ability correlates with intelligibility ratings for individual stimuli.
The noise bursts of the PPC condition, rather than masking the stimulus, reintroduce a relevant input rhythm allowing theta oscillations to correctly parse the degraded speech. When presented with the PPC condition alone, theta oscillations show strong coherence despite low intelligibility ratings. This suggests that the auditory cortex employs theta oscillations to track the speech stimulus, using low frequency rhythmic transients to parse the speech envelope into chunks of the temporal granularity optimized to license decoding.

Title: Language, lesion-behavior correlations in aphasia and resting functional connectivity networks

Authors: *A. U. TURKEN[1], N. F. DRONKERS[1,2]
[1]Res. Service, Dept of Veterans Affairs NCHCS, MARTINEZ, CA; [2]Neurol. Dept., Univ. of California, Davis, Davis, CA

Abstract: The resting-state fMRI (RS-fMRI) technique provides detailed maps of functionally connected networks of brain regions. However, the interpretation of these findings in terms of domains of cognition is not always straightforward. Further evidence from other techniques, such as task-based fMRI, metaanalysis of neuroimaging literature, and lesion studies can provide important information for the validation and interpretation of RS-fMRI-defined networks. Here, we assessed the behavioral impairments resulting from neurological damage to resting functional connectivity networks and language-related brain regions with distinct connectivity profiles. Our goals were two-fold: to improve the understanding of the lesion anatomy of aphasia; and to identify the functionally connected networks associated with different language abilities. In order to address these goals, we used brain lesion and neuropsychological data from a large group of aphasic patients, as well as RS-fMRI data from healthy individuals. Neurobehavioral and structural neuroimaging (MRI and CT) data were acquired from 154 left-hemisphere chronic stroke patients (right-handed native speakers of English, no prior neurological or psychiatric history, single event, majority involving the MCA, at least one year post-injury). The Western Aphasia Battery was administered for a comprehensive assessment of speech and language abilities. Digitally reconstructed brain lesions were transformed to MNI space for subject and group-level analyses. The RS-fMRI datasets from 25 healthy subjects were used to delineate the functionally connected networks involving the lateral surface of the left hemisphere, to derive a connectivity-based parcellation of the left lateral cortex, and to compute graph theoretical connectivity metrics of key frontal, temporal and parietal regions implicated in language. The lesion loads for each node of each rs-fMRI-based network, as well as the functional connectivity metrics characterizing each lesioned area, were correlated with behavioral deficits in different language domains and with aphasia syndrome types. Consistent with the notion that language is subserved by a broadly distributed set of interacting brain regions that extends outside the areas traditionally associated with language, aphasic syndromes and domain-specific deficits were associated with lesion patterns that are best characterized at the network-level, with the severest

deficits involving damage to multiple networks and the nodes playing central nodes in their respective networks.

Title: The distinct performance of human brain for voice identification

Authors: *Y. S. LEE[1,2], M. HANKE[3], D. KRAEMER[2,4], S. LLOYD[3], R. GRANGER[3]
[1]Ctr. For Cognitive Neurosci., [2]Psychology, Univ. of Pennsylvania, Philadelphia, PA;
[3]Psychological and Brain Sci., [4]Educ., Dartmouth Col., Hanover, NH

Abstract: How good is the human brain at distinguishing voices from other sounds? We performed machine-learning analyses of the categorization performance of twelve subjects who listened to several sound categories including human voices, animals, and man-made objects. Each sound was presented both intact, and in a spectrally rotated version in which low-level attributes were matched though the sounds overall were unrecognizable in behavioral tests.
A searchlight analysis (Kriegeskorte et al., 2006) tested for every voxel's "precision index," i.e., (true positive) / (true positive + false positive) for the category of the sound. With this stringent test, no voxels were found that were able to distinguish between the intact and rotated versions of any of the sounds except those of human voices. (Less inflexible tests did identify areas distinguishing between intact and spectrally rotated sounds at several brain loci.)
Locations in multiple brain regions were found that significantly distinguished intact from rotated human voice sounds, suggesting that (i) the ability to distinguish human voices outperforms any other auditory distinction in human brains; (ii) the distinctions were being made independent of low-level acoustic components, since these were identical in the intact and rotated sounds; (iii) many areas of the brain may participate in making these distinctions, and (iv) these findings may suggest reconsideration of the hypothesis that only very-restricted brain loci process human voices.

Title: Tone 3 sandhi and tone sequencing in Mandarin Chinese: An fMRI study

Authors: *H.-C. CHANG, O. TZENG, W.-J. KUO
Inst. of Neuroscience, Natl. Yang-Ming Univ., TAIPEI, Taiwan

Abstract: This study seeks to identify the neural correlates of Chinese tone production using functional magnetic resonance imaging (fMRI). It specifically addresses two questions: what are the neural mechanisms underlying (i) Tone 3 sandhi, a
language specific context variation acquired rather than driven on-line by ease of articulation, and (ii) lexical tone sequencing. We collected reaction time sound recording, and imaging data during the production of twelve different tone sequences. To address (i), neural responses during production of tone sequence that elicits Tone 3 sandhi, namely sequence 3333, were compared to those that do not. To address (ii), repeated and mixed tone sequences were compared, e.g. 2413 vs. 1111. To remove the effect of context dependent variation driven by ease of articulation, a context factor was derived based on the acoustic data and served as a covariate in the statistical model of the fMRI data.
The results showed that the processing of the Tone 3 sandhi involved right IFG (Brodmann area 45 & 46), right inula, right superior temporal gyru, right thalamus, and left postcentral gyrus. We believe that the right inferior frontal gyrus and insula were responsible for the core processing of Tone 3 sandhi in the preparation stage of speech production, which resulted in longer RT, while top-down modulation of the right superior temporal gyrus and the left postcentral gyrus benefited feedback monitoring. On the other hand, similar to previous study in syllable sequencing (Bohland & Guenther, 2006), mixed sequence revealed a broad left dominant network, implying that mixed sequence increased loading on both speech preparation and execution, which was reflected in longer RT and duration. Left SMA and pre-SMA, which are known to be involved in speech and motoric sequencing (Bohland & Guenther, 2006; Shima & Tanji, 1998, 2000) were included in this network. Our finding of the right lateralized network for Tone 3 sandhi supports that the advantage of right hemisphere in pitch processing extends beyond auditory analysis. We propose that right hemisphere is

specialized in processing suprasegmental signal, but once tone is combined to segments, their composite are processed in the left hemisphere. Following this proposal, the left dominant activation for mixed sequence indicates that,
unlike Tone 3 sandhi, sequencing of tonal sequence operates on the composites of tone and segment.

Title: Verbal fluency affects performance on Montreal Cognitive Assessment (MoCA) subtests

Authors: V. MATHUR KUMARASWAMY[1], M. NAIR[2], S. CHANDRASHEKAR[1], *A. K. NAIR[2]
[1]Alzheimer's Dis. Center, Quincy Med. Ctr., Quincy, MA; [2]Alzheimer Dis. Ctr., Kottayam, India

Abstract: Background: Fluency of speech is an important cognitive function. Fluency may affect components of the Montreal Cognitive Assessment (MoCA) that need verbal ability.
Methods: Using de-identified data from a memory clinic www.thealzcenter.org, we obtained baseline MoCA scores. We analyzed if fluency affected performance on verbal components of MoCA by univariate analysis and multivariate linear models including factors such as diagnosis (Alzheimer, MCI or Other), education, age, race and gender.
Results: 163 baseline MoCAs were analyzed. Fluency was related significantly to verbal subtests measuring abstraction, naming, digit span forwards and backwards, and serial subtractions (Table 1). Repetition was not significantly affected by fluency. These associations persisted in multivariate models even after adjusting for education, diagnosis, age, race, and gender as co-factors.
Conclusion: Fluency correlated with performance on abstraction, naming, digit span and serial subtraction, independent of factors such as educational status, diagnosis, age, race and gender.

Baseline Characteristics and Relationship of Verbal Fluency to Subtests of MoCA

Title: Hippocampal activity predicts successful object-location binding during short-term memory maintenance

Authors: *D. VON ALLMEN[1], K. WURMITZER[1], E. MARTIN[1], P. KLAVER[2,1,3]
[1]Universitaets-Kinderkliniken Zurich / MR-Zentrum, Zurich, Switzerland; [2]Inst. of Psychology / Univ. of Zurich, Zurich, Switzerland; [3]Zurich Ctr. for Integrative Human Physiol., Zurich, Switzerland

Abstract: In cognitive neuroscience, several studies have raised doubt on the traditional view that the hippocampus is exclusively involved in long-term memory processes [1, 2, 3]. Recent imaging studies have shown that this region might play a role in short-term maintenance of object-location associations [4, 5]. This claim has been supported by lesion studies [6, 7]. Jeneson and colleagues [8], however, proposed in another lesion study that performance in a change detection task could in fact rely on both short-term and long-term memory. According to their view the hippocampus supports long-term memory and is only used when memory load exceeds individual short-term memory capacity. These findings led us to the question whether neural activity in the hippocampus depends on object-location binding performance. In order to investigate this question, we measured maintenance-related BOLD activity in 16 healthy adults (age range 19-26 years, eight females) while they performed a visual short-term memory task probing object-location associations (set sizes 1, 2, 4 and 6; delay period = 900 ms). Two performance groups were formed (high- and low-performers; each group N=8), based on individual short-term memory capacity (Cowan's k formula [9]). We found a significant 'performance group' by 'set size' interaction within the left hippocampus (local maximum at [39, -10, -14], z=4.33, p<.001, unc.) and right hippocampus (local maximum at [36, -10, -23], z=3.54, p<.001, unc.). High-performers (mean capacity = 5.3) showed neural activity in the hippocampus at set size four and six, whereas low-performers (mean capacity = 3.8) showed activity only at set size two. At set size six, low-performers showed deactivation. These data demonstrate that neural activity within the hippocampus was related to object-location binding during successful visual short-term memory maintenance.

Title: Cognitive processing during a spatial working memory task in humans: A multivariate analysis of fMRI time series

Authors: *C. DEMANUELE[1,2], F. BÄHNER[1,2], M. M. PLICHTA[1], H. TOST[1], A. MEYER-LINDENBERG[1,2], D. DURSTEWITZ[1,2]
[1]Dept. of Psychiatry and Psychotherapy, Central Inst. of Mental Health, ZI, Mannheim, Germany; [2]Bernstein Ctr. for Computat. Neurosci. Heidelberg-Mannheim, Heidelberg University, Germany

Abstract: The radial arm maze (RAM) task has been intensely studied in rodents to elucidate neural correlates of spatial memory, decision making and reward processes. Here we employ a diverse set of multivariate statistical approaches on fMRI data recorded from a group of healthy adults during a virtual reality version of the RAM task, where subjects moved through a virtual park surrounded by various landmarks to find gold coins hidden at the end of 12 alleys.
First, various multivariate test statistics (such as Wilk's lambda) were computed separately for several regions of interest (ROIs) as a measure of the overall discriminability of different task stages (namely *encoding*, *decision*, *reward expectation*, *reward consumption*, and *delay*) within the blood oxygenation level dependent (BOLD) signal pattern. Mahalanobis distances were also calculated to identify pairwise differences between cognitively defined task epochs. Significance levels were determined non-parametrically through time series (block-permutation & time-shifting) bootstraps. Results demonstrate that those anatomical regions postulated to be involved in task execution, such as the DLPFC and ACC, and the visual areas (V1) contain significant information on the task stages which distinguishes them from non-task related (control) areas, such as the Heschl gyrus and insula. Furthermore, we found that the decoding capability of some ROIs varies with different classification schemes; e.g. the DLPFC yields the highest

discrimination between low/high memory load decisions. Neural trajectories were reconstructed from the BOLD signal using a penalized version of Fisher's linear discriminant analysis applied to delay coordinate maps constructed for each ROI. We found that within ROIs associated with cognitive load (DLPFC) or sensory (precuneus) processing, different task epochs occupied disparate regions of the state space.
Multivariate Hidden Markov Models were also employed on this self-paced task as a complementary unsupervised approach for identifying the neuronal processing stages and their sequential timing. The goodness of fit was highest for models derived from the DLPFC and visual areas. The models' output state sequences were significantly correlated with experimenter-defined behavioral labels as used in the supervised classification analysis, and this correlation was highest for those ROIs that also yield strongest separation of task epochs in the supervised approach. Thus, we conclude that different cognitive stages during performance of the RAM task can be identified and separated from BOLD time series using both supervised and, partly, unsupervised methods.

Title: Recruitment of hippocampo-neocortical networks during a spatial working memory task in humans

Authors: *F. BAEHNER[1,2], C. DEMANUELE[1,2], M. M. PLICHTA[1], H. TOST[1], D. DURSTEWITZ[1,2], A. MEYER-LINDENBERG[1,2]
[1]Dept. of Psychiatry and Psychotherapy, Central Inst. of Mental Hlth., Mannheim, Germany; [2]Bernstein Ctr. for Computat. Neurosci. Heidelberg-Mannheim, Heidelberg University, Germany

Abstract: Hippocampal-prefrontal interactions are essential for spatial navigation and memory, and disturbed in patients with schizophrenia and subjects at genetic risk. In an effort to develop translational tasks that aid in investigating this system, we have established a virtual reality version of the radial arm maze, a reward-based spatial working memory task that is widely used in rodents. During the acquisition of fMRI blood oxygenation level dependent (BOLD) data

subjects navigated through a virtual park surrounded by various landmarks to find hidden gold coins at the end of 12 alleys. The paradigm was completely self-paced and consisted of three task (training/encoding, delay, test/retrieval) and matched control phases, respectively, in each trial. The task design enforced the use of a spatial, landmark-based strategy.
Analysis of the pilot data recorded from a group of healthy subjects showed a strong recruitment of a network associated with spatial working memory and navigation. In the blocked design, we observed activations of the dorsolateral prefrontal cortex, parietal and midbrain areas (Adcock RA Neuron 2006) during both training and test phases. While activation of (para-)hippocampal areas was specific to the training phase, activation of the ventral striatum was only observed during the test period. Behavioral data was analyzed to determine when subjects encoded and retrieved information about the location of hidden rewards during the training and test phase respectively. Event-related analysis revealed that hippocampal areas are selectively recruited during encoding, while activation of parietal areas was weak. During retrieval, strong activations were found in parietal and prefrontal areas as well as the ventral striatum. Furthermore, we employed a set of multivariate statistical methods to characterize task stage-specific activation patterns (see poster by Demanuele C et al.).
Our analyses suggest a contribution of neural signals for salience related to dopamine function to the navigation task we employed, further strengthening the usefulness of this approach as a translational method to examine disorders such as schizophrenia.

Title: Working memory demand and the modulation of dorsal anterior cingulate efferent pathways revealed by fMRI and dynamic causal modeling

Authors: *H. MARUSAK, R. WHITE, S. WADEHRA, V. DIWADKAR
Dept. of Psychiatry and Behavioral Neurosciences, Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: Background: Parametric variations in working memory demand increase regional cortical-striatal responses in children and adolescents. Yet the impact on network function has

not been systematically addressed. Here we employed dynamic causal modeling (Friston et al., 2003) to investigate working memory demand-related modulation of cortical-striatal pathways with an emphasis on efferent pathways from the dorsal anterior cingulate (dACC), a primary control region in the brain.

Methods: Subjects participated in a parametric n-back (1-back + 2-back; Diwadkar et al., 2011). 64 competing model architectures were constructed with an emphasis on contextual modulation (by 1-back, 2-back or both) of pathways originating in the dACC. An *a priori* cortical-striatal network was assessed (Wager & Smith, 2003) including the dorsal prefrontal cortex (dPFC), superior parietal cortex (SPC), and basal ganglia.

Results: See Figure 1.

Discussion: Four equi-probable architectures suggest a complex implementation of a simple paradigm within cortical-striatal networks. Notably, the largest effects of contextual modulation were observed in the dACC à dPFC pathway regardless of demand (1-back & 2-back). This pattern suggests that efferent pathways originating in the dACC and to the executive core of the frontal lobe are preferentially excited regardless of demand. This pattern may reflect core mechanisms of working memory implementation, and when extended to adolescent clinical populations, these studies can provide novel characterizations of the network bases of psychiatric disorders in adolescence.

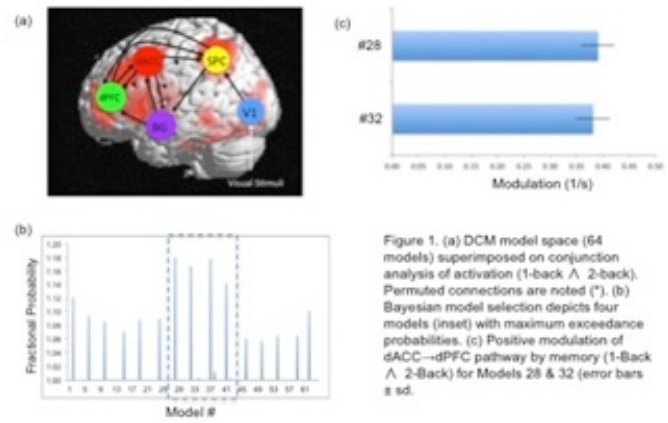

Figure 1. (a) DCM model space (64 models) superimposed on conjunction analysis of activation (1-back ∧ 2-back). Permuted connections are noted (*). (b) Bayesian model selection depicts four models (inset) with maximum exceedance probabilities. (c) Positive modulation of dACC→dPFC pathway by memory (1-Back ∧ 2-Back) for Models 28 & 32 (error bars ± sd.

Title: Activity of fronto-parietal network is reduced when subtle auditory regularities are detected.

Authors: *L. DAIKHIN, M. AHISSAR
Hebrew Univ., Jerusalem, Israel

Abstract: Previously we found that when repetition or regularity is introduced to a simple discrimination task, participants' strategy quickly changed and their performance substantially improved. Rather than actually manipulating the presented stimuli, which requires working memory, they categorized them with respect to an internal reference. We now asked whether this quick implicit switch is accompanied by modifications in the neural networks underlying performance.
We used 2 tasks, each with 2 protocols: 1) 2-tone frequency discrimination, where participants heard sequentially presented pairs of tones and had to decide for each pair which tone was higher. We tested Reference 1st protocol - the first tone was always 1000Hz and the second was higher or lower, and No Reference - there was no repeated tone. 2) Phonological awareness task, spoonerism, where in each trial participants heard word pairs and had to switch between their first phonemes. We tested a With Repetition protocol, where a small set of word pairs was repeatedly used, and No Repetition protocol, where every word pair occurred only once. Each experiment was performed during 1 fMRI run using a block design. The protocols of each experiment were measured in an interleaved manner. Within each experiment we contrasted the 2 protocols to reveal repetition-related changes in activation. We then compared the 2 resulting contrasts for possible overlaps.
Beyond the bilateral activation of the auditory cortex, activity in both the tonal and verbal tasks was left lateralized. The [no-repeat - repeat] contrast in the tone discrimination task showed a reduction of activation in explicit working memory (WM) regions (lateral-inferior prefrontal; intra-parietal) and in regions associated with syntactic processing (posterior-superior temporal sulcus) and with audio-motor integration in speech (dorsal-premotor). In the equivalent verbal contrast we found a partial overlap with the tonal contrast in WM networks in addition to areas associated with processing of verbal information (superior and middle temporal gyri), and regions associated with word processing (posterior-inferior temporal).
To conclude, we found that partially overlapping WM networks, which are left lateralized in both tasks, reduce their activity when regularity is detected. This reduction does not reflect a general decrease in task difficulty, which was equated for the frequency discrimination task by making the Reference 1st protocol more difficult. Rather, utilization of cross-trial temporal

patterns leads to a strategic switch from the laborious on-line calculations to a more automatic categorical retrieval processing.

Title: ERP marker for automatic auditory regularity detection predicts behavioral success

Authors: *S. JAFFE-DAX, M. AHISSAR
Hebrew Univ. of Jerusalem, Jerusalem, Israel

Abstract: Detection of repeated stimulation patterns (stimulus regularities) is an important learning mechanism, which is largely automatic. In the auditory system it is often tapped by ERP components as mismatch negativity (MMN) peaking ~150ms from regularity violation, and early left and right anterior negativities (ELAN and ERAN) peaking ~200ms from linguistic and musical structural violations, respectively. We now asked whether structural regularities introduced into a simple paradigm of 2-tone frequency discrimination can also be detected automatically, and whether the ability to automatically detect such a structural regularity predicts the individual's aptitude for regularity detection in other contexts.
We administered two protocols of 2-tone frequency discrimination to 35 participants, which were previously used for active discrimination. However now, participants watched a silent movie. Each protocol had a simple structural regularity - in each trail (separated by 1400ms) one of its two tones (separated by 600ms) was fixed across trials (1000Hz-reference) and the other was higher or lower. In protocol1 it was the 1st tone whereas in protocol 2 it was the 2nd. Our previous behavioral data (Nahum et al., J Neurosci 2010) indicated that protocol 1 was performed significantly better even though its objective complexity is equal to that of protocol 2. Participants' automatic ERP response at ~200ms from the onset of the 1st stimulus (P2) was larger in protocol 1, where the 1st tone is the repeated reference, than in protocol 2. This difference indicates that participants detected the structure of protocol 1, and produced a larger response to the repeated reference, even though it was locally surrounded by non reference

stimuli. No such difference was found in response to the 2nd tone, indicating that participants did not detect the structure of the "less favorable" protocol 2. Our participants were also tested with few cognitive tasks. Their automatic sensitivity to the auditory structure was correlated with their sensitivity to visual regularities in word spelling, i.e. their rate of discriminating correct versus incorrectly spelled frequent words. These findings reveal that automatic regularity detection can be tapped even without structural violation. Moreover, automatic sensitivity predicts behavioral success in a range of tasks, both at the group (protocol asymmetry) and at the individual level.

Title: Tapping working memory with sensorimotor synchronization

Authors: *N. JACOBY[1,2], H. JAKOBY[1], I. LIEDER[1], N. TISHBY[1], M. AHISSAR[1]
[1]Hebrew University,, Jerusalem, Israel; [2]Music Dept., Bar Ilan Univ., Givaat-Shmuel, Israel

Abstract: Traditionally, sensory
and motor tasks were considered related to low-level processing. Reverse
Hierarchy Theory, suggested by Ahissar and Hochstein (Nature 1997), challenges
this view by emphasizing the importance of top-down processes in sensory tasks
that were traditionally considered as low level. In this study, we give
evidences that a motor task -sensorimotor synchronization- is also linked with
high-level processes, mainly ones that involve working memory.
Sensorimotor
synchronization, the temporal coordination of a rhythmic movement with an
external rhythm, is studied experimentally by tapping experiments (Repp 2005)
in which subjects are required to finger tap in synchrony with an auditory
stimuli. One type of tapping experiments is the step-changes experiment,
where subjects are required to adapt their taps to a metronome alternating
between two tempi. Repp and Keller 2004 showed that this type of
experiment is modulated by cognitive load, and depends on explicit processing.
They conjectured that this could be explained by the importance of period

correction, a theoretical concept that models the adaptation of the internal time-keeper tempo in the sensorimotor control loop. Our motivation for this study was to trace cognitive processes that are linked to period correction. Subjects (N=30) performed
a battery of cognitive and sensory tasks, and two-step tapping experiments. We found high positive inter-subject correlations between successful performance in the tapping experiment (decreased tapping variance) and working memory related tasks, the highest correlation to an n-back auditory task, in which subjects are required to report whether the current tone matches a tone n-steps earlier (n is changed adaptively). We also found significant correlations to other tasks that pound on verbal or tonal memory. However, the Block Design task, a standard spatial-reasoning visual task, usually considered to measure general cognitive abilities and not directly related to working memory, did not show a significant correlation.
We propose that these
correlations can reflect the involvement of high-level working memory mechanisms for the representation of tempo in the sensory motor control loop, and therefore in line with the Reverse Hierarchy Theory's predictions.

Title: Short-term memory for visual features: inferior frontal junction initiates maintenance processes in the frontal eye fields

Authors: *M. H. SNEVE[1], S. MAGNUSSEN[1], D. ALNÆS[1], T. ENDESTAD[1], M. D'ESPOSITO[2]
[1]Dept. of Psychology, Ctr. For the Study of Human Cognition, Univ. of Oslo, Oslo, Norway; [2]Helen Wills Neurosci. Institute, Univ. of California Berkeley, Berkeley, CA

Abstract: Short-term memory (STM) encoding and maintenance of simple visual features involve interactions between retinotopic visual cortex (VC) and a set of regions in frontal cortex. Specifically, the Inferior Frontal Junction (IFJ) has been associated with memory encoding, while the Frontal Eye Fields (FEF) show sustained activity during memory intervals, indicative of a role in maintenance of the memory trace. The patterns of influence between these areas during the different stages of a STM task are however poorly understood. In the present study, we adapted the delayed orientation discrimination task to enable separation of responses associated with memory encoding, maintenance, and retrieval in a fMRI experiment. The study also included measures of responses to identical stimuli either passively viewed, or actively encoded but not associated with a memory task. The aim was two-fold: (i) to investigate with univariate analyses how individual areas contribute to the different STM stages; (ii) to examine effective connectivity (Granger Causality (GC)) between regions of interest (ROI) to get further insight into the function of the different nodes.
The BOLD-response was significantly stronger during encoding than during retrieval and control conditions in a set of higher-tier visual areas and in IFJ, but not in FEF. Furthermore, FEF, but not IFJ or VC, showed significant sustained activity during the retention interval. No differences were found between retrieval and encoding of non-STM-related stimuli in any of the areas. These results suggest that the VC-FEF-IFJ network plays a central role in STM encoding and maintenance. To elucidate the temporal dynamics of the network, we extracted ROI time-series from task periods representing memory encoding and retrieval, and for periods following control stimuli. Bivariate GC analysis between ROI-pairs showed that IFJ and VC influenced FEF during the memory encoding stage. The pattern was significantly different from the influences during retrieval and control conditions, and could thus not be due to vascular properties of the ROIs. To investigate whether VC's influence on FEF during encoding was contingent on IFJ, we ran a second GC analysis, conditioning on IFJ. No significant GC was observed from VC to FEF when the variance explained by IFJ was removed from the calculations, indicating that the influence of VC on FEF is mediated by IFJ.
Our results suggest that IFJ together with VC is particularly involved during STM encoding. The observation that FEF shows maintenance-related activity, and is preceded by IFJ, fits well with the developing understanding of IFJ as a control region with an initiating role in STM operations.

Title: A high-resolution fMRI study of hippocampal subfield and medial temporal lobe structures during the maintenance of overlapping and non-overlapping stimuli

Authors: *R. E. NEWMARK, K. SCHON, R. S. ROSS, B. JUN, C. E. STERN
Ctr. For Memory and Brain, Psychology Dept., Boston Univ., Boston, MA

Abstract: Computational models and experimental studies suggest a critical role for medial temporal lobe (MTL) regions in working memory (WM) tasks. Experimental work also suggests a critical role for the hippocampus in disambiguation, an episodic memory process. However, whether delay period activity in the hippocampus and MTL cortex is related to WM processes or to episodic memory processes is unclear. Here, we probed WM with a load manipulation, and episodic memory with a manipulation of disambiguation during encoding. We used high-resolution fMRI (Siemens 3T; voxel size, 1.5mm3; TR, 2 s) to explore the recruitment of hippocampal subfields (CA1, CA3/DG, subiculum) and surrounding MTL subregions (amygdala, perirhinal, entorhinal, parahippocampal cortices) when participants maintained overlapping (OL) and non-overlapping (NOL) stimuli at two different WM loads. We predicted that MTL cortex, but not the hippocampus would show a load effect during the Sternberg task delay, while the hippocampus and MTL cortex would show greater delay activity for the OL than for the NOL condition. Nineteen participants (12 men; age, 23.0 ± 4.19) performed a modified Sternberg task (Schon et al., 2009). Participants encoded either 2 or 4 OL or NOL stimuli which they then maintained across a 10-s delay. After the delay, they indicated whether a test stimulus was a match or non-match to one of the stimuli seen before the delay. OL stimuli were pictures of unfamiliar, morphed composite faces sharing 30% of their features. NOL stimuli were distinct, unmorphed, unfamiliar faces. Analysis of accuracy and reaction time showed that participants performed better on load 2 than load 4 trials and on NOL than OL trials. During the delay period, a two-way ANOVA on the fMRI data (WM load - load 4 vs. load 2 by condition - OL vs. NOL) showed a main effect of condition (OL > NOL) in CA1 and MTL cortex, while a main effect of load (Load 4 > Load 2) showed extensive activation in the CA3/DG, CA1, and subiculum and in the surrounding MTL cortex. A significant interaction between load and condition was localized to CA1, the amygdala, and the parahippocampal cortex. An examination of parameter estimates showed that for NOL stimuli, CA1, and amygdala were engaged to maintain a greater WM load. In the parahippocampal cortex, increased activity was shown for maintaining OL information at a greater load. Our data shows that CA1 is bilaterally recruited to maintain larger WM loads of distinct, NOL representations. Our results provide evidence for a

role for hippocampal subfields and MTL subregions to support both WM and episodic memory processes during the WM task delay.

Title: Involvement of the cerebellar cortex and nuclei in verbal and visuospatial working memory: A 7T fMRI study

Authors: *M. THÜRLING[1,2], H. HAUTZEL[3,4], M. KÜPER[1], M. R. STEFANESCU[1,2], S. MADERWALD[2], M. E. LADD[2,1], D. TIMMANN[1]
[1]Univ. Clin. Essen, Essen, Germany; [2]Erwin L. Hahn Inst., Essen, Germany; [3]Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; [4]Forschungszentrum Jülich, Jülich, Germany

Abstract: The aim of the study was to investigate whether different areas of the cerebellar cortex and nuclei contribute to different working memory tasks (n-back vs. Sternberg tasks). Young and healthy subjects participated in two functional magnetic resonance imaging (fMRI) studies using a whole-body 7T MR scanner (Magnetom 7T, Siemens, Erlangen, Germany). One group of subjects (n = 21) performed an abstract and a verbal version of an n-back task contrasting a 2-back and 0-back condition. Another group of subjects (n = 23) performed an abstract and a verbal version of a Sternberg task contrasting a high load and a low load condition. A block design was used. Normalization of the cerebellar cortical data was done based on the spatially unbiased atlas template (SUIT) of the human cerebellum (Diedrichsen, 2006). For image processing of the dentate nuclei, a recently developed region of interest (ROI) driven normalization method was applied (Diedrichsen et al., 2011). Whereas activated areas of the cerebellar cortex and dentate nuclei were not significantly different comparing the abstract and verbal versions of the n-back task, activation in the abstract and verbal Sternberg tasks was significantly different. In both n-back tasks activation was most prominent at the border of lobules VI and Crus I, within lobule VII, and within the more caudal parts of the dentate nucleus

bilaterally. In Sternberg tasks the most prominent activations were found in lobule VI extending into Crus I on the right. In the verbal Sternberg task activation was significantly larger within right lobule VI compared to the abstract Sternberg task and compared to the verbal n-back task. Activations of rostral parts of the dentate were most prominent in the verbal Sternberg task, whereas activation of caudal parts predominated in the abstract Sternberg task. The lack of difference between abstract and verbal n-back tasks and the lack of significant lateralization suggest a more general contribution of the cerebellum to working memory regardless of the modality. In contrast, the focus of activation in right lobule VI in the verbal Sternberg task suggests specific cerebellar contributions to verbal working memory. The verbal Sternberg task emphasizes maintenance of stimuli via phonological rehearsal, whereas central executive demands prevail in n-back tasks. Based on the model of working memory by Baddeley and Hitch (1974), the present results show that different regions of the cerebellum support functions of the central executive system and one of the subsidiary systems, the phonological loop. No evidence, however, was found that the cerebellum supports the second slave system, the visuospatial sketch pad.

Title: Regional brain activity during updating in working memory

Authors: *C. READ[1], T. D. WAGER[3], E. E. SMITH[2,4], J. X. VAN SNELLENBERG[2]
[2]Div. of Cognitive Neurosci., [1]New York State Psychiatric Inst., New York, NY; [3]Univ. of Colorado at Boulder, Boulder, CO; [4]Dept. of Psychology, Columbia Univ., New York, NY

Abstract: The network of brain regions supporting working memory (WM) has been well elucidated through neuroimaging research. However, the tasks commonly used in neuroimaging work on WM have limited the extent to which some component processes of WM can be isolated. Here we report preliminary results (N = 8) from a functional Magnetic Resonance Imaging study of a novel WM task that allows for separation of the process of updating the contents of WM from encoding and rehearsal of the target information. During the delay between target and probe stimuli in a letter item recognition task,

participants were instructed to either add or subtract an item from the target set or to simply rehearse the initially presented stimuli. Unlike a traditional item recognition task, this allows for analysis of brain regions involved when suppressing or adding a stimulus that is presented directly. Comparison of events in which participants added stimuli to the target set to simple rehearsal revealed activation in language processing and selection regions (left ventrolateral prefrontal cortex) as well as dorsal anterior cingulate and pre-supplementary motor area, supplementary motor areas, and bilateral insula. Comparison of subtracting items from the target set to simple rehearsal revealed no significant activation, suggesting a substantial difference in the neural demands of updating in WM between adding and dropping information. While other work has shown that dropping information results in additional activation, tasks used in those studies appear to place greater demand on cognitive control. Results of this preliminary investigation show that adding new items to working memory load induced activation in regions similar to those activated by simple WM maintenance, while subtracting items did not induce any significant activation, indicating that adding, but not dropping items engages brain regions understood to be involved in working memory.

Title: Influence of response modality on fMRI activity in a working memory task

Authors: *A. PILACINSKI, M. WALLSCHEID, A. LINDNER
Hertie Inst., Tuebingen, Germany

Abstract: Most fMRI experiments investigating short term memory require certain behavioral measures, such as manual or verbal responses, in order to control for the memorized content. It remains unknown, however, if the memory-related activity observed by such studies solely reflects the current memory content or, in addition, depends on the effector used to respond. In

the present study we addressed this issue by investigating the modulation of working memory related BOLD signals as a function of response modality.
We scanned a total of 10 subjects, performing a spatial memory task. At the beginning of each trial, subjects were instructed that they will have to respond either verbally or by pressing an appropriate button of a button box. Then, a set of objects was presented for a limited amount of time. After a memory maintenance phase, subjects had to report whether a second set of objects, which was presented in the response phase, was identical to or different from the initial set of objects presented. This condition was contrasted with a simple control task, where subjects were also instructed initially about which effector to use but, instead of memorizing any spatial information, they had to only determine whether a set of dots presented in the response phase was symmetrical or not. Importantly, in both tasks the required motor responses were not predicted by the initial cues and thus could not be pre-planned.
We performed a region of interest-based analysis in areas that were significantly activated during the memory maintenance phase, as compared to a corresponding period of the control task. We then analyzed BOLD signals extracted from these regions and compared them between verbal and manual response modality, as well as for different memory loads (2/6 objects). Our analyses revealed a significant interaction between response modality and memory load in the right dorsal premotor cortex. Specifically, activity in this area was higher for “manual” than for “verbal” conditions, however for low memory loads, only. This effect did not reach significance for high memory load conditions. Importantly, we did not observe a similar effect in the control task, which argues against the idea that the observed difference could be simply due to unspecific motor preparation.
Our results demonstrate that the response modality affects BOLD-activity related to memory maintenance processes. This finding implies that encoding and maintenance of information within working memory may be optimized not only with respect to the content of information, but also with respect to the behavioral context in which this information is to be used.

Title: Working memory revisited - are category and process specific models orthogonal or mututally exclusive?

Authors: J. P. WONG, A. M. OWEN, *A. HAMPSHIRE
The Brain and Mind Inst., London, ON, Canada

Abstract: Working memory maintenance (WM) refers to the process of actively holding information on-line in mind. It forms one of the core components of goal-directed behaviour, being necessary for reasoning, comprehension and fluid intelligence with impairments evident in many neurological diseases. While the frontal and parietal cortices (FPC) are known to play a key role in WM the exact cognitive and neural architecture remains in dispute. In particular, one long standing debate that has never been fully resolved is what role specific frontal-lobe regions contribute to stimulus-specific processing (e.g. locations versus objects) versus stimulus-independent (category insensitive) processing.
To examine whether FPC regions are differentially active based on stimulus category, 19 participants took part in a novel WM fMRI study. Stimuli of three distinct types were displayed - positions, numbers and objects - each at three levels of load (3, 5 or 7 items). Participants were required to encode and maintain this information over a delay period and subsequently identify the non-encoded item in a probe array. Regions of FPC cortex that had previously been implicated in a broad range of cognitive task contexts (Multiple demand cortex - MD) were first examined using predefined regions of interest (ROI), including the anterior insula/frontal operculum, inferior frontal sulcus and inferior parietal cortex. These MD regions were highly active at all task stages regardless of stimulus type, supporting a process specific (stimulus-independent) model. However, voxel-wise whole brain analysis revealed that other FPC regions, including the superior frontal sulcus, inferior frontal gyrus and frontal polar cortex, were responsive specifically to the location or object properties, supporting a category specific model. Furthermore, parametrically modulating the number of items affected MD regions during encoding for all categories of stimuli, whereas other FP regions outside of MD showed category specific load effects. There were no significant effects of number of items during the delay anywhere within FPC cortex.
These results suggest that models of frontal-lobe control of WM that include category- and process- specific functional axes may not, as was previously believed, be mutually exclusive. More specifically, there appears to be a central core of MD regions that are 1) category unresponsive, 2) involved in encoding and maintenance, but 3) only sensitive to load during encoding. Concurrently, there exists another set of category responsive FP regions outside of MD that do conform to the posited ventral-dorsal/object-location dissociation.

Title: Distinct neural correlates of visual working memory number and resolution: An fMRI investigation

Authors: *H. SCHWARB[1], S. D. KEILHOLZ[1], R. A. MCKINLEY[3], L. TRIPP[3], E. H. SCHUMACHER[2]
[1]Georgia Inst. Tech., ATLANTA, GA; [2]Georgia Inst. Tech., Atlanta, GA; [3]Air Force Res. Lab., Wright-Patterson Air Force Base, OH

Abstract: Since antiquity, philosophers and scientists have been interested in human memory; today, researchers are still working to understand its boundaries and architecture. One popular theory of working memory capacity (WMC) identifies a limit of approximately four items (Cowan, 2001). Consistent with this theory, neuroimaging research shows that activity in the intraparietal and intraoccipital (IPS/IOS) sulci reflects visual WMC and reliably tracks the number of items stored (Todd & Marois, 2004). This capacity limit is not, however, universally accepted and some researchers have proposed that visual WMC is strongly influenced by the complexity of the items stored (Alvarez & Cavanagh, 2004). Furthermore, storing items of varying complexity results in distinct patterns of neural activity (Xu & Chun, 2006). Awh, Barton, and Vogel (2007) have recently proposed a unifying account of visual WMC suggesting that visual working memory is mediated by two independent factors: number (number of it ems stored) and resolution (amount of detail stored). The current study investigates the unique neural correlates of number and resolution using the change detection task. Data suggest that number is mediated by regions previously associated successful memory formation including right hippocampus and right IPS/IOS. Conversely, resolution is independently mediated by regions previously associated with sustained attention and working memory such as left dorsolateral prefrontal cortex. These results suggest distinct neural activity independently supporting the general number and resolution processes responsible for identifying changes among complex stimuli.

Title: Distinct dorsal and ventral posterior cingulate responses to internally and externally directed memory processing

Authors: *R. LEECH, G. SCOTT, D. J. SHARP
Med., Imperial Col. London, London, United Kingdom

Abstract: Introduction
Attention can be directed internally or externally. During the retrieval of autobiographical memories attention is directed towards information from an individual's past. In contrast, when behavior is guided by external events, attention is focused on the environment. Mesulam argues that this distinction is reflected in neuroanatomy. Limbic structures process internally-directed information such as memories whereas sensory/motor cortices process external information. Paralimbic structures such as the posterior cingulate cortex (PCC) may form a link between regions involved in processing internally or externally derived information.
We use functional MRI to directly compare processing that is directed either internally or externally. Based on a hypothesis originating from our previous work (Leech et al. J Neurosci 2011) we test whether dorsal and ventral parts of the PCC show distinct responses when memory involves internally stored information (autobiographical and episodic memory) or external information (working memory).
Methods
Neural activity was studied in twenty subjects using functional magnetic resonance imaging. Four conditions with varying levels of internal and external attentional focus were performed: 1) autobiographical memory (AM) retrieval; 2) episodic memory retrieval (EM) of information presented around 1 hour prior to scanning; 3) a zero-back task, in which subjects responded to a specific word; 4) a two-back task, in which subjects responded when the word was the same as the one presented two previously.
Results
We have previously demonstrated distinct responses in dorsal and ventral PCC regions during performance of the externally-focused N-back (tasks 3 and 4). Our results extend this work by directly comparing PCC responses on the N-back with responses observed during internally-focused autobiographical and episodic memory retrieval. Relative to the undemanding zero-back

condition, activation in the whole of the PCC decreased during two-back performance. In contrast, activity in the ventral PCC and retrosplenial cortices increased during AM relative to zero-back, and was unchanged during EM.

Conclusions

The results support a functional distinction between dorsal and ventral parts of the PCC during different types of memory. Relative reduction in PCC activity is seen during working memory, where attention is directed externally. In contrast, activity increases in the ventral PCC for internally directed memory, in particular during autobiographical memory. This suggests the PCC is a heterogeneous region involved in regulating the balance between internally and externally directed attention.

Title: Responses, mappings, and dimensions distinguishing preparatory processes in the PFC.

Authors: *T. KRIETE[1], J. REYNOLDS[2], R. O'REILLY[3]
[1]Univ. of Colorado Boulder, Boulder, CO; [2]Univ. of Colorado Denver, Denver, CO; [3]Univ. of Colorado Boulder, Boulder, CO

Abstract: Recently, there has been substantial interest in identifying how different areas of the prefrontal cortex (PFC) may be involved in cognitive control processes. In particular, one popular hypothesis is that lateral PFC is organized such that posterior areas are sensitive to concrete pieces of information (such as information regarding a response), whereas more anterior areas are sensitive to abstract pieces of information (such as information regarding the dimension of a stimulus to attend to). However, recent data suggest that this type of gradient might interact with working memory demands; relatively anterior areas of PFC (e.g. mid-dorsolateral PFC) appear to be associated with high memory demand conditions, irrespective of how abstract the to-be-maintained information is. The goal of the current study was to directly investigate this issue using event-related functional magnetic resonance imaging (fMRI). Specifically, the current study used a cueing paradigm in which participants were presented with a four different types of preparatory cues prior to an imperative stimulus. They could be presented with: a) low-

abstraction information associated with the response (right vs. left hand), b) high-abstraction information associated with the relevant stimulus dimension (visual contrast vs. size), c) information associated with the relevant stimulus-response mapping ("large" values mapped onto index vs. middle finger), and d) a null cue that controls for visual stimulation and timing, but does not provide relevant information regarding the upcoming probe. Critically, the current paradigm used a catch-trial design in which cue-related and probe-related processes can be dissociated.
Results indicate that participants used each of the content cues to prepare for upcoming probes. Further, results indicated that, relative to the null cue, all of the content cues were associated with increased cue-related activity in various different areas of lateral PFC, including mid-dorsolateral PFC and areas of the inferior frontal junction (IFJ). The current data suggest that these areas are associated with preparatory working memory processes, irrespective of how abstract the information is.

Title: Limited attentional capacity for emotional information with negative valence: An fMRI study with cognitive load

Authors: *T. MINAMOTO[1], M. OSAKA[3], N. OSAKA[2]
[2]Psychology, [1]Kyoto Univ., Kyoto, Japan; [3]Human Sci., Osaka Univ., Suita, Japan

Abstract: The present study challenged a research question that attentional resource for emotional information is limited as is the case for perceptual information. In the field of visual selective attention, it is shown that visual working memory load attenuates interference effect by a visual distractor when the category of load and that of distractor overlaps. The less interference effect is attributed to depletion of attentional resource available for processing of distractors.

Based on the two-dimensional framework for emotional experiences (valence and arousal), the present study manipulated the emotional valence and tested if distractor interference decreases as a function of emotional valence. Participants performed the emotional Stroop task (positive or negative valence) while maintaining negative emotional information in working memory. Three types of memory load was given (high negative, low negative, none), and its effect on the emotional Stroop task was measured. Brain activation was also obtained while participants performed the task. Given that attentional resource for emotion is valence-based, the interference effect in the emotional Stroop task with negative valence should be weakened as memory load increased. Behavioral analysis on the Stroop task showed a main effect of the emotion, but not a main effect of the load and an interaction between the load and emotion. However, fMRI data showed that the activation of the anterior cingulate cortex and the orbitofrontal cortex showed less activation when participants performed a Stroop task with negative valence under high memory load than under no memory load. Considering the fact that activation of the anterior cingulate cortex reflects emotional conflict, less activation of the region under high memory load means smaller interference effect. Such load effect was not observed in the emotional Stroop task with positive valance. Interestingly, small volume correction analysis focusing on the bilateral amygdala showed that high negative emotional load produced greater activation than no emotional load during emotional Stroop task with negative valence. Those results indicate that higher emotional load depletes attentional resource for processing emotional distractor, possibly consuming the resource of amygdala. The present study provides the evidence that attentional resource for negative emotional information is valence-based.

Title: Neural evidence for the flexible use of working memory and episodic memory in prospective remembering

Authors: *J. D. COHEN[1,2], J. A. LEWIS-PEACOCK[1,2], K. A. NORMAN[1,2]
[1]Princeton Neurosci. Inst., [2]Dept. of Psychology, Princeton Univ., Princeton, NJ

Abstract: How do we remember to execute a specific goal at the appropriate time while busily pursing other plans? We can use an effortful strategy -- actively maintaining the goal information in working memory -- or a reflexive strategy -- relying on external cues to trigger retrieval of the goal information when it is needed (McDaniel & Einstein, 2000). The flexible choice of strategy involves a tradeoff between effort and performance, and depends on many factors including the availability of cognitive resources and the likelihood of goal retrieval. We designed an fMRI study to assess whether brain activations can track, on a trial-to-trial basis, the use of working memory versus episodic memory to achieve a delayed goal. Each trial began with a target picture, followed by a variable-length sequence of 2-sec memory probes each containing two pictures and a letter string. Participants were required to balance two orthogonal goals: 1) to make repeated lexical judgments (about the letter strings that appeared in the sequence of probes); and 2) to identify when the picture target reappeared (between 2 and 42 sec after its introduction). For half the trials, the lexical judgment was simple, while for the other half it was more difficult. We reasoned that when a trial involved a series of lexical judgments that was more demanding, participants would be less likely to maintain the picture target in working memory, relying instead on retrieval from episodic memory. We also varied the degree of proactive interference associated with the target. In half the trials, it was drawn from a large heterogenous set of trial-unique pictures (low interference), while in the other half it was drawn from a small homogenous set that repeated frequently across trials (high interference). We reasoned that high proactive interference would interfere with episodic memory retrieval, thereby biasing participants to use working memory to maintain the target. We used multivariate pattern analysis of the fMRI data in ventral temporal cortex to identify the target-related activity during each trial. We also identified brain regions (e.g., inferior parietal cortex) for which activity reflected successful episodic memory retrieval of the target. In all trials, prospective memory success was associated with elevated estimates of target activation at the moment that it reappeared. Critically, sustained target activation prior to its reappearance was predictive of success only on those trials with low evidence of episodic retrieval activity. Together, these findings provide initial neural evidence for the flexible use of working memory and episodic memory in prospective remembering.

Title: Second-order false belief task needs working memory in normal adults: An event-related fmri study based on theory of mind

Authors: *N. OSAKA[1], K. YAOI[1], T. MINAMOTO[1], M. OSAKA[2]
[1]Psychology, Kyoto Univ., Kyoto, Japan; [2]Psychology, Osaka Univ., Osaka, Japan

Abstract: Theory of Mind (ToM) allows us to attribute empathies, desires, and intentions to others to predict or explain their actions and to posit their intentions (mindreading). ToM testifies an ability to make inferences about others' mental state and allows us to understand what we believe to be true and what is true may be different (Perner, 1991). Children under the age of four, along with most autistic children of older ages are likely to fail to perform 1st order False Belief Task (FBT) like the Sally-Anne task. We assumed one of the causes of the failure would due to insufficient/immature executive function of working memory. Thus, we applied 2nd order FBT as more sophisticated mindreading task to normal adults to examine simultaneous DLPFC activation related to working memory using an event-related fMRI. We thought the higher-order meta-representations based on working memory are prerequisited to solve the task. Results showed brain activations in the dorsal working memory network involving bilateral DLPFC and posterior parietal cortex (PPC) as well as the cortical midline structures including bilateral MPFC and precuneus in under the 2nd-order FBT. Those results indicate that the dorsal working memory network plays a critical role in the higher-order mindreading.

Title: In and out of focus in working memory: Neural evidence of role of long-term memory

Authors: *C. BASAK[1], M. I. CUNHA[1], C. HAMILTON[2]
[1]The Ctr. for Vital Longevity, Univ. of Texas At Dallas, Dallas, TX; [2]Rice Univ., Houston, TX

Abstract: Working memory has been argued to constitute of 2-tiers in memory updating paradigms- a core focus of attention (FoA) of 1 item, with representations outside the focus are activated long-term memory (LTM; Verhaeghen & Basak, 2005). Accessing the representations outside the focus involves focus switching. If the representations outside the FoA are unpredictable, a controlled search process is indulged; else, the focus switch is constant (Basak & Verhaeghen, 2011a, 2011b). In short-term memory paradigms, enhanced MTL activation has been found for items presented before the last item, provided support for focus of 1 and activated LTM outside the FoA (Ozetkin et al., 2008, 2010).
The goals of the current study is to establish a) whether representations outside the FoA are indeed activated LTM, b) neural evidence for the search process outside the focus, and c) whether neural activations of representations outside the focus correlate with success in various short-term memory/WM tasks outside the focus. We designed a novel memory updating paradigm where WM set-size (N) varied from1 to 3, and we manipulated the stimulus predictability across blocks for N>2.
Behavioral results support our prior results - faster retrieval speed and higher accuracy were observed for N=1; for N>1, retrieval speed increased with N for unpredictable, but remained constant for predictable probe sequence.
N=1, compared to N>1, yielded enhanced activations in dorsolateral PFC, cingulate gyrus, cuneus, and precuneus. For N>1, versus FoA, enhanced activations are observed in insula and parahippocampus/hippocampus (PHCG); activations of both brain regions were greater for unpredictable than predictable probe sequences. Brain-activation-by-task-complexity functions indicate that increases in PHCG were linear, with no increase in the most complex condition (unpredictable N=3). Individuals with higher short-term or working memory capacity (e.g., forward and backward digit span) and faster retrieval rates outside the focus also displayed greater activations in in left and right PHCG for N>1. The results suggest that representations outside the focus are activated LTM indicated by activations in MTL; these activations increase with more effortful search for active representations, and are correlated with both capacity and retrieval speed of WM.

Title: Evidence for a different role for the ipsilateral Area MT in human Visual Working Memory in motion discrimination

Authors: *P. KÖRTVELYESSY
Cognitive Neurol., Hertie Inst. For Clin. Brain Res., Tübingen, Germany

Abstract: Recent psychophysical experiments analysing motion discrimination in non-human monkeys and humans revealed a critical spatial separation resulting in a decline of the discrimination threshold in visual working memory (VWM). This critical spatial separation was conform to a putative receptive field of area MT neurons in non-human monkeys and maybe in humans also. These results pointed to a spatiotopic component in the directly activated Area MT in visual working memory, which could not be verified in human fMRI and non-human monkeys with single-cell recordings. The human fMRI results rather showed a holoistic activation including the ipsilateral Area MT; especially together with feature-based attention.
We conducted two psychophysical experiments (both with 4 participants and 500 trials each) to glimpse at the role of the ipsilateral Area MT in human VWM. We used different random-dot-kinematograms (RDK) with different noise levels being presented in both visual hemifields during a match-to-sample task and determined the level of 75% correct matching/motion discrimination per position. The positions of the RDK had different spatial separations. Eye position was monitored and recorded via an eyetracker. This data was filtered and trials with eye movements bigger than 3 degrees were deleted.
If the ipsilateral Area MT played the same part in human VWM as the contralateral it would show the same critical spatial separation as the directly activated contralateral Area MT. We could not find a critical spatial separation for the ipsilateral side in our first experiment (one factor repeated measures ANOVA for position p=0,405). In our second experiment we added a RDK as a cue, which should have activated the ipsilateral Area MT via feature- based-attention. Again no critical spatial separation could be found (one factor repeated measures ANOVA for position p=0,2886). Also, there was no significant difference between these two experiments in terms of the motion discrimination thresholds (ttest=0,4605).
Therefore we conclude that the human ipsilateral Area MT does not seem to play the same role in human VWM as the directly activated Area MT. In our experiments the ipsilateral Area MT does not have the same spatial component as stated for the directly activated Area MT. The relevance of the activity measured in the fMRI in the human ipsilateral Area MT remains elusive.

Title: Representations of remembered objects depend on task

Authors: *S.-H. LEE, D. J. KRAVITZ, C. I. BAKER
NIH/NIMH, Bethesda, MD

Abstract: When we bring an object to mind, some aspects of the object are often emphasized whereas other aspects are ignored. For example, when remembering the same object, we can focus on its visual shape (i.e. physical property) or on its usage or category (i.e. semantic property). While prior studies have implicated prefrontal cortex in aspects of retrieval and working memory, it is unclear what role it and more caudal perceptual regions play in maintaining the retrieved information dependent on the emphasized properties. To address this issue, we used functional magnetic resonance imaging (fMRI) at 7 Tesla to investigate the representation of objects across whole brain regions during two delayed-match-to-sample tasks emphasizing either physical or semantic aspects of the objects. In the physical task, participants were asked to decide whether an object part presented after the delay period belonged to the remembered object. Whereas in the semantic task, they had to determine whether the test image was from the same category. We focused on two primary regions-of-interest identified using independent data: an object-selective region in ventral temporal cortex and a task-responsive region in lateral frontal cortex. In each region we measured whether the multi-voxel response pattern could be used to decode the remembered object during the delay period. In the physical task, the response of object-selective, but not prefrontal cortex, could be used to decode the identity of individual remembered objects. In contrast, during the semantic task, prefrontal, but not object-selective regions, showed significantly distinct representations for each remembered object. To examine what kind of information is actually maintained during the tasks, we performed a behavioral experiment using images or words as distracters during the delay period. The physical task was more impaired with image than word distracters, whereas the opposite was true in the semantic. This result suggests that participants mainly maintained the appropriate physical or semantic properties of the objects during the delay period. Altogether, the imaging and behavioral results suggest that the distribution of information about remembered objects is dependent on the nature of the information that the task demands. Object-selective areas are primarily involved in maintaining visual, but not semantic, information whereas prefrontal areas are primarily involved in maintaining semantic, but not visual, information.

Title: Associations between socioeconomic status and cortical thickness in prefrontal cortical subregions

Authors: *G. M. LAWSON, J. T. DUDA, J. WU, B. B. AVANTS, M. J. FARAH
Univ. of Pennsylvania, Philadelphia, PA

Abstract: Childhood socioeconomic status (SES) is associated with disparities in executive function performance, and SES differences have been observed in measures of prefrontal cortical function, but little is known about the structural correlates of childhood SES in prefrontal cortex. Structural MRI data from a sample of 283 healthy children from the first time point of data collection in the National Institute of Health (NIH) Magnetic Resonance Imaging (MRI) Study of Normal Brain Development were used to systematically investigate the association between childhood SES and cortical thickness in subregions of prefrontal cortex. T1-weighted MRI data were processed using Advanced Normalization Tools (ANTs) and the associated pipelining framework PipeDream. Cortical thickness, the shortest distance between the white matter surface and pial gray matter surface, was estimated within prefrontal regions of interest (ROIs) using the Diffeomorphic Registration Based Cortical Thickness (DiReCT) algorithm. Hierarchical linear regression was then used to assess the association between two principal measures of childhood SES, family income and parental education, on cortical thickness in ten prefrontal ROIs and three asymmetry measures. After correcting for multiple comparisons and controlling for age, sex, total brain volume, BMI, IQ, and race, higher parental education significantly predicted increased cortical thickness in the right anterior cingulate gyrus and left superior frontal gyrus. Scatterplots of parental education and cortical thickness in these regions, adjusted for covariates,

are shown in Figure 1. These results suggest that brain structure in frontal regions may provide a meaningful link between SES and cognitive function among healthy, typically developing children.

Title: Early childhood home environment predicts frontal and temporal cortical thickness in the young adult brain

Authors: *B. AVANTS[1], L. BETANCOURT[2], J. GIANNETTA[2], G. LAWSON[3], J. GEE[3], M. FARAH[3], H. HURT[2]
[1]Philadelphia, PA; [2]Children's hospital of Philadelphia, Philadelphia, PA; [3]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Introduction: Evidence from animal models suggests that the early environment has long-term consequences on later cognitive functioning and brain development. Little work has been performed in human subjects to test whether normal variation in early experience has measurable long term effects on the brain [1,2].
Methods: Our analysis leverages 64 participants from a low socioeconomic status background who were followed from birth and who underwent T1 and diffusion tensor (DT) MR imaging on a Siemens 3T Trio. Each subject underwent the HOME assessment at age 4. MRI was collected later in life in both 29 male (a.a. = 19.4 ± 1.17) and 35 female (a.a. = 19.1 ± 1.30) subjects. Differences in the age of the cohort distribution and in parental IQ between males and females

are not significantly different. Each subject also underwent the HOME assessment at age 4 which is a questionnaire that may be used to quantify a more cognitively stimulating and emotionally supportive home. In this work, we use neuroimaging and machine learning-based statistics to efficiently test the hypothesis that networks supporting cognition should be enhanced by increased stimulation and nurturance during childhood. Our statistical model, implemented in the R programming language, controls for age, gender and parental IQ.
Results and Discussion: Our results show, for the first time, that cortical thickness in early adulthood is reduced (independently from parental IQ) by increased quality of the home environment at age 4. These results, which identify a novel network of cortical regions that are directly influenced by parental behavior, appear in Figure 1. A further analysis revealed that early cognitive stimulation has a stronger effect on frontal lobe cortical thickness in female subjects ($p < 0.0069$) than in males ($p < 0.5000$) and that the temporal lobe regions are related to verbal comprehension as measured near the time of imaging. This is one of the few studies to confirm the effect of normal variability in the home on neuroanatomy.

Title: Neural correlates of socioeconomic status in the developing human brain

Authors: *S. HOUSTON[1,2,3], E. KAN[1,2], E. R. SOWELL[1,2], K. G. NOBLE[4,5,6]
[1]Dept. of Pediatrics, Children's Hosp. Los Angeles, Los Angeles, CA; [2]Keck Sch. of Med., [3]Dept. of Psychology, USC, Los Angeles, CA; [4]Dept. of Pediatrics, [5]GH Sergievsky Ctr., Columbia Univ., New York, NY; [6]New York Presbyterian Hospital/Columbia Univ. Med. Ctr., New York, NY

Abstract: Introduction: Socioeconomic disparities in childhood are associated with remarkable differences in cognitive and socio-emotional development during a time when dramatic changes are occurring in the brain. Yet, the neurobiological pathways through which socioeconomic status (SES) shapes development remain poorly understood. Behavioral evidence suggests that language, memory, social- emotional processing, and cognitive control exhibit relatively large differences across SES. Here we investigated whether volumetric differences could be observed across SES in neural regions that support these skills, including the hippocampus, the amygdala, the anterior cingulate cortex and several structures in a language-supporting network in the left temporal, temporo-occipital and frontal cortices.
Methods: Sixty typically developing, socioeconomically diverse children (31 female) were recruited, ranging in age from 5 to 17 years (Mean=11.4, SD=3.1). Participants had no history of neurological impairment, psychiatric disability, learning disability, language impairments, developmental delay, or significant exposure to prenatal teratogens such as alcohol. Two to four sagittal T1-weighted images were collected for each participant using the following parameters: TR= 1900 ms; TE= 4.38 ms; flip angle, 15; matrix size, 256x256; voxel size, 1 x 1 x 1 mm; acquisition time, 8 min 8s. Pre-processing and definition of cortical and subcortical gray matter regions on structural images were conducted using automated brain segmentation software (Freesurfer, 4.5). First, relationships between SES and regional cortical volume were explored. Next, we examined the degree to which the effects of SES factors on regional brain volume might change with age, by examining SES x age interactions in each ROI.
Results: Highly significant SES differences in regional brain volume were observed in the hippocampus and the amygdala. Specifically, higher parental education levels predicted larger amygdala volumes, whereas higher income-to-needs ratios predicted larger hippocampal volumes. In addition, SES x age interactions were observed in the left superior temporal gyrus and left inferior frontal gyrus, such that children from higher SES families showed relatively greater volumetric increases with age in these regions. These results were not explained by differences in gender, race or IQ. Likely mechanisms include differences in the home linguistic environment and exposure to stress, which may serve as targets for intervention at a time of high neural plasticity.

Title: Effects of childhood socioeconomic status on cognition and related neural systems in adulthood

Authors: *E. PAKULAK, Y. YAMADA, A. HAMPTON WRAY, E. ISBELL, H. NEVILLE
Psychology, Univ. of Oregon, EUGENE, OR

Abstract: A large and growing literature documents the profound impact of lower socioeconomic status (SES) on cognitive skills and brain structures and functions in children (Hackman, Farah, & Meaney, 2010). In previous event-related potential (ERP) studies we have reported that lower SES children display reduced neural modulation by selective attention compared to higher SES children (Stevens, Lauinger, & Neville, 2009) and that neural systems supporting attention are modifiable by training (Stevens et al., 2008; Neville et al., 2011, under review). We have also reported that the relationship between SES and cognition persists into adulthood, as childhood SES predicts both native language proficiency as well as the ERP response to syntactic processing in adult native speakers (Pakulak & Neville, 2010). Here we show that this relationship extends to other aspects of cognition and to a different, more ecologically valid ERP language processing paradigm. Finally, we present preliminary evidence suggesting that certain aspects of these systems may be malleable in adults from lower SES backgrounds. Typically developing adults from a wide range of SES backgrounds were administered a comprehensive battery including measures of working memory and language and three ERP paradigms assessing selective attention and different subsystems of language. Childhood SES was significantly predictive of working memory in adulthood. Employing the same ERP measures of attention previously employed (e.g., Stevens et al., 2009), we found that adults from higher SES backgrounds showed enhanced neural modulation by selective attention to linguistic probe stimuli compared to adults from lower SES backgrounds. Using an ERP language paradigm featuring a more ecologically valid context, we replicated and expanded our previous findings (Pakulak & Neville, 2010). Adults from higher SES backgrounds and who scored higher on standardized measures of language proficiency showed neural responses

consistent with greater maturity to both semantic and syntactic violations. Finally, we provide evidence that aspects of attention are trainable in adults. We measured attention/executive function abilities of parents of lower SES children randomly assigned to either an evidence-based parenting program or one of two control groups and observed improvements in specific aspects of attention after eight weeks in the parent training program only. These results suggest that the effects of lower childhood SES on the development of multiple cognitive systems extends into adulthood, but also that such effects may be ameliorated by training in adulthood.

Title: Effects of SES on neural mechanisms supporting multiple subsystems for language processing

Authors: *H. J. NEVILLE, E. PAKULAK, Y. YAMADA, A. HAMPTON WRAY
Univ. of Oregon, Eugene, OR

Abstract: A growing literature documents the profound impact of lower socioeconomic status (SES) on cognitive skills and brain structure and function in children (Hackman, Farah, & Meaney, 2010). Numerous studies have shown that children from lower SES families have reduced language abilities compared higher SES peers (Hart & Risely, 1995; Huttenlocher, 2002; Noble, McCandliss, & Farah, 2004). Previously we showed that early neural indices of selective attention, a key factor important for school readiness, are reduced in lower SES children (Stevens, Lauinger, & Neville, 2009). We have also demonstrated that attention systems in lower SES preschoolers are highly modifiable. Following an eight-week parenting training and attention training program for children, children's cognition and neural mechanisms of attention improved significantly compared to a passive or an active control group (Neville et al., 2011; under review).
Among the aspects of cognition to improve following training was receptive language, consistent with previous findings suggesting that brain functions for language are highly sensitive to differences in experience early in development. However, previous studies of neural systems

mediating language processing in young children are limited and few, if any, examine the relationships between neural indices of language and SES. We developed a novel, ecologically valid paradigm containing naturally spoken sentences accompanied by an animated video in a coherent narrative to assess language processing indexed by event-related potentials (ERPs). We examined the relationships between neural subsystems for language and SES in 3-5 year-old children. Our child-friendly paradigm contains semantic and phrase structure violations and canonical controls. Semantic violations elicited smaller N400 amplitudes in the higher compared to the lower SES group, consistent with a more mature pattern for semantic processing. Syntactic violations elicited a biphasic response. The late-onset precursor to the typical adult anterior negativity began earlier and was larger in amplitude in the higher compared to the lower SES children. This suggests SES-related differences in the maturation of systems hypothesized to underlie more automatic syntactic processing in adults. The later positive component resembling the P600 was comparable across groups. These results add to the literature by documenting that SES impacts neural mechanisms underlying multiple neurocognitive systems, including specific subsystems for language. There is an urgent need for evidence-based educational programs that can ameliorate the large and growing achievement gap in the US.

Title: Girls and boys with Autism Spectrum Disorders show different stochastic signatures of movement decision time and pointing kinematics

Authors: *J. V. JOSE[1,2], R. W. ISENHOWER[4], E. B. TORRES[5,3]
[1]Office of the Vice President for Res., Indiana Univ., Bloomington, IN; [2]Cell. and Integrative Physiol., [3]Neurol., Indiana Univ., Indianapolis, IN; [4]Psychology, [5]Psychology, Ctr. for Cognitive Science, Ctr. for Computat. Biomedicine Imaging and Modeling, Rutgers Univ., New Brunswick, NJ

Abstract: Current inventories used to diagnose Autism Spectrum Disorders (ASD) apply similar criteria to boys and girls despite well-established differences prevalent across the course of normal development between the genders. Recent work suggests that girls with ASD run the risk

of receiving a delayed diagnosis, potentially missing a critical window of opportunity for early intervention. Here we address this question in the context of natural behaviors. Children used variants of a simple computerized match-to-sample task using pointing gestures to communicate their choice. The forward, ***task-relevant*** component of the pointing gesture was contrasted with the retracting, ***task-incidental*** component. We assessed gestural kinematics in tandem with cognitive parameters of the decision making process over hundreds of repetitions in each of 30 children (12 girls, 18 boys, 4-16 years old). Sensory-motor gestural parameters included linear and angular speed timing (head, trunk, arm segments) towards and away from the target. Cognitive parameters included the speed and accuracy of the decision. The experiments took place in the naturalistic settings of the classroom. The random fluctuations of the gestures and cognitive parameters across hundreds of repetitions revealed highly skewed frequency distribution. Their stochastic signatures uniquely localized each child in the Gamma probability distribution parameter plane with 95% confidence level.. Across the broad ASD spectrum, from low-functioning to TD, the Gamma distribution captured the range of stochastic variability signatures from exponential to normal. Dramatic gender-specific and cognitive performance-specific effects separated the variability of each gender group and that of each individual. Specifically, the signatures of the boys with ASD were in the exponential range of the Gamma phase space. The TD fell intermediate in the skewed range and those of the girls with ASD were in the Gaussian range. Plotting the girl's parameter data in a log-log plot revealed a scaling effect with a well characterized by a power-law relation (linear regression R-square 0.99, rmse 10^-4, slope 1.002, intercept 0.005) whereby early in development girls with ASD fall closer to TD girls but as they age their signatures dramatically shift along the line. We discuss these results in terms of a marked gender-dependent sensory-motor difference. Our results invite reconsidering gender specificity in ASD relative to the broader spectrum of human performance: from autistic to typical, in particular, early subtle differences in girls' performance towards typicality should not mislead clinicians and delaying diagnosis.

Title: Statistical classification tools for autism spectrum disorders: motor variability across the autism spectrum and beyond

Authors: *R. W. ISENHOWER, III[1], J. V. JOSÉ[2], E. B. TORRES[1]
[1]Psychology, Rutgers Univ., Piscataway, NJ; [2]Physics, Indiana Univ., Bloomington, IN

Abstract: Autism Spectrum Disorders (ASD) are characterized by a constellation of neurodevelopmental problems encompassing social, communicative, and sensory-motor impairments. Manifestations of the disorder vary from low-functioning to high-functioning/Asperger's (HFA/AS). Autism purportedly occurs more often in families of physicists, engineers, and mathematicians (Baron-Cohen et al., 1998) and instruments, such as the Autism Quotient (AQ), indicate that individuals in these fields are more likely to score similarly to those with HFA/AS (Baron-Cohen et al., 2001). Instead of exclusively relying on surveys that make inferences about social functioning, here we take an objective sensory-motor based approach and directly measure the statistical structure of the random fluctuations of the variability of physical movements, which serve as re-afferent sensory input. We reasoned that this input may be utilized differently by individual with different cognitive predispositions. To test this idea, we map stochastic signatures of several movement trajectory parameters and compared them across the human cognitive and sensory-motor continuum--from non-verbal low-function autism, to those with HFA/AS, to individuals from a variety of cognitive predispositions/backgrounds (literature, psychology, biology, engineering, computer science, physics, mathematics). We use the Gamma probability distribution family to characterize with 95% confidence the variability of pointing trajectories in each individual using maximum likelihood estimation. We find that the severity of ASD (or its absence) correlates well with an individual's location of his/her stochastic signatures in the Gamma-parameter plane. When deliberately pointing to a target, the variability of peak linear velocity of non-verbal individuals falls in the exponential range of the Gamma. While HFA/AS are in the skewed range, those mathematically inclined who scored high on the AQ, fall in the normal range of the Gamma. Assessment of the time to reach peak linear velocity of retracting task-incidental motions yielded the exact opposite trend. According to these objective sensory-motor metrics individuals who scored high on the AQ may not necessarily have HFA/AS, but rather fall along the broad spectrum of cognitive and sensory-motor behavior. Furthermore, differentiating individuals at this end of the spectrum may become more difficult after AS is subsumed under Autistic Disorder in the DSM-5. The present results therefore invite complementing current clinical evaluations with objective sensory-motor metrics of behavior to help resolve ambiguities at the upper end of the autism spectrum.

Title: Structural connectivity predicts risk for dyslexia in kindergarteners

Authors: *Z. M. SAYGIN[1], E. S. NORTON[1], D. E. OSHER[1], S. D. BEACH[1], A. B. CYR[1], O. OZRANOV-PALCHIK[2], N. GAAB[2], J. D. E. GABRIELI[1]
[1]Brain and Cognitive Sci., MIT, Cambridge, MA; [2]Labs of Cognitive Neurosci., Children's Hosp. Boston, Boston, MA

Abstract: Developmental dyslexia, defined as an unexplained difficulty in learning to read, is quite prevalent and has been associated in children and adults with alterations in white matter organization as measured by diffusion-weighted imaging (DWI). It is unknown, however, whether these differences in structural connectivity are related to the cause of dyslexia, or instead are consequences of reading difficulty (e.g., far less reading experience, or the development of compensatory brain organization). Here, we examined the relation of white-matter organization to major behavioral predictors of dyslexia, including phonological awareness (PA) for language sounds, in 20 kindergartners (mean age=5.6 years, 9F), who had little or no reading instruction. We examined white matter tracts known to connect critical components of language and reading networks, specifically the inferior longitudinal (ILF) and arcuate fasiculus (SLFa), using a tracts of interest (TOI) approach with probabilistic tractography and also at the whole brain level. TOIs were defined using a new automated method (TRACULA/FreeSurfer/FSL) that reliably defines major tracts in each participant's native diffusion images using tractography and anatomical priors based on manual labeling. We measured volume, fractional anisotropy (FA), radial (RD) and axial diffusivity (AD) in three TOIs bilaterally: ILF, SLFa, and a control tract (parietal section of SLF). The relationship between these diffusion measures and behavioral assessments, including PA, were tested by means of cross-validation correlations. Whole brain regressions of behavioral scores with diffusion measures were also performed.
Superior composite PA scores were significantly and positively correlated with the volume and FA of left SLFa, but not with any other tracts/measures, including controls of head size and SNR variance. The correlation was selective, since other behavioral measures associated with risk for dyslexia, such as naming fluency, did not correlate with SLFa volume or FA. We next explored which PA tasks drove the correlation with left SLFa. Left SLFa tract volume, AD, and FA,

correlated only with Blending Words (and not with Elision or Non-Word Repetition). Whole-brain models of these diffusion measures were consistent with the TOI analyses.
These findings reveal that the left SLFa, which has been frequently associated with poor reading in previous studies, is already smaller and has lower FA and AD in kindergarteners at risk for dyslexia because of poor PA. This suggests a structural basis of risk for dyslexia that predates reading instruction.

Title: Hippocampal and prefrontal reorganization underlies the maturation of fact retrieval: A longitudinal fMRI study in young children

Authors: *S. QIN, S. CHO, M. ROSENBERG-LEE, D. GEARY, V. MENON
Dept. of Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA

Abstract: Basic fact knowledge lies at the foundation of human cognitive development. The ability to efficiently retrieve basic facts from memory and bring them to bear in constantly changing situations is a key characteristic of mature problem solving in children. During development, children's math problem solving skills become gradually dependent on memory-based strategies such as direct retrieval, and less dependent on effortful procedures such as counting. Little, however, is known about neurodevelopmental mechanisms underlying these transitions in children.
We conducted a longitudinal functional magnetic imaging (fMRI) study to investigate neurodevelopmental changes associated with increased use of retrieval strategies in children's mathematical learning. Participants included thirty 7 to 9-y-old children who were scanned twice ('Time 1' & 'Time 2') separated by 18 months. During scanning, children were instructed to solve a set of single-digit addition problems. Each child's mix of strategies for solving problems was assessed using a standardized and well-validated measure that classifies strategies based on

experimenter observation and child self-reports. Functional brain images were acquired on a 3T GE Signa scanner using a T2* weighted gradient echo spiral in-out pulse sequence.
We found that the use of retrieval strategies in children increased over time whereas counting strategies decreased over time. These behavioral results suggest that with time children became more reliant on memory-based strategies. fMRI analyses of the two time points replicated a widely distributed frontoparietal network involved in solving addition problems. Importantly, comparing 'Time 2' with 'Time 1' for solving addition problems revealed significantly greater activation in the bilateral hippocampus. In contrast, there was reduced activation in the bilateral dorsolateral prefrontal cortex (DLPFC) and right angular gyrus (AG) over time.
Over an 18 month period children became less dependent on counting strategies and more dependent on retrieval strategies while solving addition problems. This transition was paralleled by increased hippocampal and decreased DLPFC and AG engagement over time. Our behavioral and neuroimaging findings provide important evidence that the transition from counting to more efficient retrieval-based strategies is characterized by greater reliance on the hippocampal memory system and decreased reliance on the prefrontal cortex. Our findings have important implications for understanding knowledge acquisition in early childhood.

Title: Individual differences in adolescents' ability to filter items for working memory predict neural structure and function.

Authors: *A. S. FINN[1], M. A. SHERIDAN[4], J. SALVATORE[2], J. LEONARD[2], J. GABRIELI[3]
[1]MIT, Cambridge, MA; [2]Dept. of Brain and Cognitive Sci., MIT, Boston, MA; [3]MIT, Department of Brain and Cognitive Sciences, MA; [4]Dept. of Developmental Med., Children's Hosp. Boston, Boston, MA

Abstract: The ability to filter information into or out of working memory (WM) predicts an individual's WM capacity or the amount of information (no longer present in the environment) that one can hold in mind (Vogel, McCollough, & Machizawa, 2005). Evidence from both infrahuman primate neurophysiology and human neuroimaging has highlighted the importance

of basal ganglia structures, including the caudate and putamen, in the filtering of information into WM (Pasupathy & Miller, 2005; McNab & Klingberg, 2008). WM ability has been shown to be related to myriad measures of learning, school outcomes, and general fluid intelligence, so the ability to filter-or gate access to WM-may be important in development and education. In the present study, we asked whether the basal ganglia plays a similar role in the brains of adolescents, and whether variation in basal ganglia function and structure is related to WM variation among adolescents. We administered a WM filtering task during functional MRI in which adolescents were asked to remember either 4 or 2 stars that were presented on a screen. Adolescents were told that a cue (a circle or a square) would indicate whether they would need to keep all of the stars in mind over a delay or whether they would have to remember a subset of the stars (i.e., filter irrelevant information out of WM). Data from 15 adolescents (aged 13 to 16, mean 14.8; 6 females) reveals that individual differences in the ability to filter information are related to 1) two separate measures of working memory ability (nback: r=.57 , p=.067; count span: r=.4, p =.1), 2) the degree to which the prefrontal cortex is recruited during the delay period for working memory (r=.554, p =.032), 3) the degree to which the basal ganglia are recruited while holding information in mind (r=.569, p=.027) and 4) the volume of the caudate (r= -.481, p =.070) across individuals (anatomically defined). These behavioral, functional and structural relationships converge to highlight the importance of filtering for working memory in adolescents. These data suggest that ongoing development of the basal ganglia-and not just the prefrontal cortex-should be considered in thinking about the development of WM ability during adolescence.

Title: Emotional memory consolidation over mid-day sleep in early development

Authors: *L. B. KURDZIEL, J. KENT, R. M. C. SPENCER
Univ. of Massachusetts, Amherst, MA

Abstract: The circadian sleep-wakefulness rhythm changes throughout development. Serum cortisol levels demonstrate a distinct circadian rhythmicity, with adult-like amplitudes, by the

age of 6 months; however, children do not develop the adult-like monophasic sleep pattern, consolidating sleep to one nocturnal bout, until 4-6 years of age. The mid-day nap must therefore play an important role in development. Children 33-60 months of age ('preschool children') rapidly develop emotional processing skills. A recent study and decades of anecdotal evidence, suggests that mid-day sleep plays a role in emotional processing at this age: Children are emotionally dysregulated in the absence of a mid-day nap. In young adults, it has been suggested that emotional memories are prioritized for consolidation over sleep. As such, we hypothesized that mid-day naps benefit emotional regulation by consolidating recent emotional memories. To examine this, preschool children (mean age = 51.7 +/- 6.7 months) were tested on their memory for faces described as either "mean," or "nice." Children were tested following a typical mid-day nap and an equivalent period of wake. All were tested in both conditions, separated by 1-3 weeks, to control for differences in brain maturation and only children who napped at least 60 minutes were included in the analysis (n = 28). Memory performance was not different immediately following a nap and wake period. However, when tested the following day, a delayed benefit of the prior day's nap was seen: Memory for faces was significantly better when children had napped the day before ($F(1,22) = 4.22$, $p = 0.05$). Nap-dependent consolidation was greatest for mean faces ($t(22) = 1.68$ $p = 0.05$). Moreover, the total time spent napping for all children correlated with overall memory performance improvement ($r = 0.33$, $p = 0.03$). Finally, the benefit of sleep on memory was exaggerated in children with initial low memory performance, and this was true for both mean ($t(33) = 4.03$, $p < 0.001$) and nice ($t(33) = 2.14$, $p = 0.04$) faces. These results support a role of mid-day sleep in emotional memory consolidation during development. The delay in observing the benefit of sleep is similar to that reported in song birds: Juvenile zebra finches decreased song performance following sleep yet those that performed worse over sleep actually learned the song the best overall in the long-term.

Title: Lateralisation of myelination during postnatal development relates to language ability

Authors: *J. O'MUIRCHEARTAIGH[1,2], D. DEAN, III[1], H. DIRKS[1], N. WASKIEWICZ[1], K. LEHMAN[1], B. JERKSKY[1], S. DEONI[1]
[1]Advanced Baby Imaging Lab, Sch. of Engin., Brown Univ., Providence, RI; [2]Dept. of Neuroimaging, King's Col. London, Inst. of Psychiatry, London, United Kingdom

Abstract: Background: The human cerebral hemispheres are functionally lateralized for specific cognitive domains, e.g. language, spatial processing. This is reflected by gross anatomical and functional asymmetry in adulthood. Although functional lateralization develops over time from infancy to childhood to adulthood, structural connectivity is likely to mediate this lateralization through more efficiently myelinated axonal bundles. The representation of this asymmetry at birth and its development remains unclear.
Objective: Here we use a quantitative myelin-specific MRI technique to index white matter asymmetry over the whole brain in a cohort of children under the age of 6, hypothesizing that the degree of structural lateralization will increase with age.
Methods: 109 children (66 Male) between the ages of 12 and 72 months (mean 37.3m) took part in this study. MRI data was collected using the mcDespot sequence (Deoni et al, 2008), a relaxometry technique that allows calculation of the myelin water fraction, a more specific, quantitative measure of myelin content. Each dataset was flipped on the sagittal axis and both images were spatially normalized to a custom pediatric template in approximate MNI space using ANTS (Avants et al, 2008), spatially smoothed with a 6mm Gaussian kernel, and a scaled lateralization index was created for every subject (L-R)/(L+R). A general linear model modeling for mean lateralization, age and gender was designed. The resulting model was estimated voxelwise by permutation and considered significant at $p<0.05$ corrected for multiple comparisons.
Results: Significant leftward asymmetries were detected in the anterior cingulum bundle and mesial frontal regions, anterior thalamus and caudate, as well as visual, temporal, and motor (localized over the hand knob) cortical areas. Rightward asymmetry was detected in the external capsule, as well as Heschl's gyrus. Frontal asymmetry significantly predicted receptive language scores ($F=6.363$, $df=1,92$, $p<0.013$).
Discussion: The resulting asymmetry of myelin volumetric quantity indicates that myelination differences are occurring in both focal cortical areas and basal ganglial cortical loops (anterior thalamus, caudate and mesial frontal; putamen, ventral frontal). The frontal leftward lateralization specifically was functionally meaningful, relating significantly to receptive language ability. However, this lateralization didn't significantly change with age or gender, though actual myelin quantity increases with age. This indicates that cerebral lateralization may be biologically constrained prior to functional development, and may predict cognitive ability.

Title: Does the resting state connectivity have hemispheric asymmetry? A near-infrared spectroscopy study

Authors: *A. V. MEDVEDEV
Ctr. for Functional and Mol. Imaging, Georgetown Univ. Med. Ctr., WASHINGTON, DC

Abstract: Near-infrared spectroscopy (NIRS) is a promising new technology for low-cost noninvasive brain imaging suitable for use in virtually all subject and patient populations. Numerous studies of brain functional connectivity using fMRI, and recently NIRS, suggest new tools for the assessment of cognitive functions during task performance and the resting state (RS). We analyzed functional connectivity and its possible hemispheric asymmetry measuring coherence of optical signals at low frequencies (0.01-0.1 Hz) in the prefrontal cortex in 13 right-handed (RH) and 2 left-handed (LH) healthy subjects at rest (4-8 min) using a continuous-wave NIRS instrument CW5 (TechEn, Milford, MA). Two optical probes were placed bilaterally over the inferior frontal gyrus (IFG) and the middle frontal gyrus (MFG) using anatomical landmarks of the 10-20 system. As a result, 28 optical channels (14 for each hemisphere) were recorded for changes in oxygenated (HbO) and deoxygenated (HbR) hemoglobin. Global physiological signals (respiratory and cardiac) were removed using Principal and Independent Component Analyses. Inter-channel coherences for HbO and HbR signals were calculated using Morlet wavelets along with correlation coefficients. Both coherence- and correlation-based Fisher-transformed connectivity matrices showed qualitatively similar patterns of connectivity which was higher within each anatomical region (IFG and MFG) and between hemispheres (e.g., left IFG <-> right IFG) than between IFG and MFG in the same hemisphere. Laterality indexes were calculated as t-values for the ‘left > right’ comparisons for each regional group of channels in each subject. In the right-handed group, the laterality indexes were relatively small and variable with still significantly higher connectivity in the right hemisphere in the majority of RH subjects. In contrast, the LH subjects had highly negative laterality indexes thus demonstrating a significantly greater hemispheric asymmetry with the dominance of the right hemisphere

compared to the RH group.
Our data further demonstrate the feasibility of using NIRS for the analysis of resting state functional networks. NIRS-based connectivity patterns correspond well to the anatomical and functional compartmentalization of the prefrontal cortex (e.g., inferior and middle frontal gyri). Furthermore, the results provide first evidence on the hemispheric asymmetry of the RS connectivity which is especially strong in the left-handed individuals. These data encourage further exploration of the NIRS connectivity and its application for the analysis of hemispheric relationships within the functional architecture of the brain.

Title: Neural-dissection of motivational processes underlying personality traits

Authors: *T. GONEN[1,2], E. ELDAR[4], T. HENDLER[1,2,3]
[1]Functional Brain Center, Tel Aviv Sourasky Med. Ctr., Tel Aviv, Israel; [2]Sch. of Psychological Sci., [3]Sagol Sch. of Neuroscience, Dep. of Physiol. and Pharmacol., Tel Aviv Univ., Tel Aviv, Israel; [4]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: Motivation is a psycho-behavioral concept which refers to the drive to facilitate or inhibit behavior in response to environmental incentives and threats. The “Reinforcement Sensitivity Theory“ (RST) is an animal based neurobehavioral model comprising three distinct systems involved in motivational processes, which we have recently validated in humans via fMRI. These motivational tendencies were further conceptualized as core personality traits of Sensitivity to Reward (SR) and to Punishment (SP). However, since reinforcements (both appetitive and aversive) carry the hedonic value of pleasure (i.e. "liking"), along with motivational value of incentive (i.e. “wanting"), it is important to dissociate these two processes in order to elucidate the neural correlates underlying personality related motivational processes. We conducted an fMRI study in 50 healthy participants using a novel competitive computer game which was constructed to manipulate approach and avoidance tendencies. The goal of the

game is to catch rewarding coins, and avoid punishing balls. Additionally, uncontrolled events of random rewards and punishments allow for separation of the intentional (incentive) from unintentional (hedonic) rewarding or punishing events. Following the brain scan, subjects completed the Sensitivity to Punishment and Sensitivity to Reward Questionnaire (SPSRQ). We used whole brain GLM analysis including four regressors derived from intentional and unintentional, reward and punishment events, to functionally identify the neural correlates of motivational processes related to wanting and liking. We further used the hippocampus, a key node of the RST motivation system, as a seed region for functional connectivity (FC) analysis, in order to assess the mutual operation of different motivational systems throughout the game and its relation to SR/SP personality traits.
We established dissociation between an incentive-action related network and hedonic DMN-like evaluative network. Furthermore, FC from the hippocampus revealed several key regions of the RST motivational systems such as the ventro-medial PFC (vmPFC) and amygdala. Moreover, differences in FC patterns were found to be related to the individual differences in SR/SP traits: stronger FC of the vmPFC with hippocampus was associated with higher RS but lower PS; whereas for the amygdala, FC with hippocampus was stronger for higher RS and PS.
Our findings suggest that personality traits related to motivation manifest as differential connectivity patterns between the sub-systems of the RST, rather than relating to a single sub-system's regional activation.

Title: A case of isoniazid-induced delirium

Authors: *B. DEMARTINI, O. GAMBINI
A.O. San Paolo, Milan, Italy

Abstract: ABSTRACT:
Objective: to report a case of isoniazid induced delirium
Case summary:
A 56-year-old man affected by alcoholism and hepatic cirrhosis was admitted to hospital for a suspected pneumonia with pleural effusion and thickenings. A Mantoux skin test was positive. A

core biopsy of the pleural nodules revealed a tubercular granulomatous pleuritis. An isoniazid, ethambutol and rifampicin therapy was then started. Subsequently the patient developed a state of delirium. A diagnostic work-up was carried out considering different hypothesis: hepatic encephalopathy was ruled out because of lack of response to appropriate treatment; negative encephalic CT scan, liquor examination and EEG excluded a tubercular involvement of the central nervous system or other neurologic etiologies. Haloperidol and delorazepam were administered under the suspicion of Wernicke-Korsakoff syndrome, without any benefit. Finally a toxic etiology was considered. Among isoniazid side effects psychosis is described, though rare. Isoniazid therapy was then stopped and substituted by moxifloxacin, with progressive improvement of the state of consciousness.
Discussion:
Cases of isoniazid-related psychiatric disorders reported include psychosis, obsessive-compulsive disorder and mood alterations. Two mechanisms are generally considered as responsible: pyridoxin deficiency and isoniazid toxicity, a molecule chemically near to iproniazid, a powerful monoamineoxidase inhibitors. This is the first report of a case of isoniazid-induced pure delirium, with all clinical features according to DSM-IV criteria. We also confirmed successful resolutions of symptoms only by discontinuation of therapy.
Conclusions: in the work-up of a state of delirium, when investigating the toxic hypothesis, clinicians should consider neuro-psychiatric side effects of isoniazid.

Title: Intrinsic hemispheric autonomy and its relation to functional lateralization

Authors: D. WANG[1], R. L. BUCKNER[2], *H. LIU[1]
[1]Athinoula A. Martinos Center, Dept. of Radiology, Massachusetts Gen. Hosp., Charlestown, MA; [2]Psychology, Harvard Univ., Cambridge, MA

Abstract: Certain functional systems of the human brain are strongly lateralized. Here we explored the asymmetric brain organization by quantifying the hemispheric interaction using intrinsic functional connectivity and investigated its relation to functional lateralization. We first introduce a novel concept, termed hemispheric autonomy, as the difference between within-hemisphere and cross-hemispheric connectivity. Hemispheric autonomy is computed on each voxel by subtracting the degree of cross-hemisphere connectivity from within-hemisphere connectivity. Both can be estimated based on the spontaneous activity measured by fMRI. Hemispheric autonomy was estimated for 1000 young adults. Strong autonomy was observed in left inferior prefrontal and temporal regions involved in language processing. Strong autonomy was also observed in right lateral frontal, insula and angular gyrus regions that associate with attentional control. Previous studies have suggested that these regions are among the most lateralized regions. Minimal autonomy was found in the motor, somatosensory, auditory and visual cortices. We next investigated the relation between hemispheric autonomy and language lateralization. 56 subjects participated in a semantic decision task. Autonomy in a left hemisphere mask, derived from the 1000 subjects, was estimated for each of the 56 subjects. We found that autonomy at rest correlated with language lateralization during the task ($r = 0.52$), indicating that the balance between within- and cross-hemispheric connectivity is associated with functional lateralization. Finally, a prefontal region that is involved in the frontoparietal control network showed strong autonomy in both hemispheres, implying that this region in different hemispheres may play different functional roles. To test this hypothesis, we used the brain parcellation recently reported by our group (Yeo et al., 2011) and computed autonomy for each of 7 functional networks across the 1000 subjects. In the left hemisphere, a significant correlation was found between the autonomy in the frontoparietal control network and the language/default network ($r = 0.49$). However, in the right hemisphere, the autonomy in the frontoparietal control network showed its strongest correlation with the attention network ($r = 0.51$). These results tentatively support the hypothesis that the frontoparietal network may be involved in the control of different functional elements in the two hemispheres.

Title: Daytime sleepiness is associated with a loss of default mode network connectivity in cognitively intact elderly

Authors: *A. M. WARD[1,2,3], A. P. SCHULTZ[1,3], D. G. MCLAREN[1,3,4], W. HUIJBERS[1,3], E. C. MORMINO[1,3], T. HEDDEN[1,3], R. A. SPERLING[1,3,2,5]
[1]Massachusetts Gen. Hosp., Charlestown, MA; [2]Psychiatry, Brigham and Women's Hosp., Boston, MA; [3]Athinoula A. Martinos Ctr. for Biomed. Imaging, Charlestown, MA; [4]GRECC, Edith Nourse Rogers Mem. Veterans Hosp., Bedford, MA; [5]Ctr. for Alzheimer Res. and Treatment, Boston, MA

Abstract: Background: A set of cortical brain regions, collectively known as the default mode network (DMN) exhibit coherent activity during rest. DMN coherence can be quantified using functional connectivity magnetic resonance imaging (fcMRI) and has been suggested as a candidate biomarker for detecting early changes related to Alzheimer's Disease (AD). Specifically, decreases in DMN connectivity have been associated with mnemonic deficits and amyloid-β plaque pathology, but also "normal aging". The sleep-wake cycle is disrupted in AD, and these relationships may be detectable before the onset of symptoms. However, the relationship between chronic sleepiness and DMN connectivity in non-demented elderly individuals remains unclear.
Methods: Eighty-four elderly subjects (age 73.2±5.7 years, 44 male) were administered the Epworth Sleepiness Scale (ESS) questionnaire, a subjective rating of sleepiness, and underwent a resting-state fcMRI scan. A subset of subjects (n=75, age 72.6±5.6 years, 39 male) was assessed with a battery of neuropsychological (NP) examinations. A confirmatory factor analysis was applied to this NP data and factor loadings for 6 factors (Speed, Executive Function, Memory, Fluency, Switching, and Working Memory) were derived.
For the fcMRI analyses, we extracted timeseries data from a set of previously published seed regions (8mm diameter spherical) in the posterior cingulate cortex (MNI [0 -53 26]), medial prefrontal cortex ([0 52 -6]), and lateral parietal cortices (averaged between [-48 -62 36] and [46

-62 32]). The seed timecourses were correlated, normalized using Fisher's z, and averaged to produce a global measure of DMN integrity.
Results: We found that increasing daytime sleepiness was associated with decreased global DMN coherence. The correlations between nodes were also significantly related to ESS scores. We found no relationship with ESS and correlations between bilateral seeds in motor cortex, or between the DMN and three other cortical networks. We did not find a relationship with ESS and neuropsychological scores, except a trend-level relationship between increasing ESS scores and decreasing factor scores for the Speed factor, consistent with previous work. All analyses controlled for age.
Conclusion: A self-reported measure of chronic daytime sleepiness in cognitively intact elderly subjects is related to decreased DMN coherence during resting-state. Additionally, there is a trend-level relationship between NP speed of processing and sleepiness. These findings may have important implications for elucidating age-related and AD-related alterations in sleep and network dysfunction.

Title: Estimated cortical gray matter myelination of 1500 human brains using partial volume corrected T1- and T2-weighted MRI images.

Authors: *R. SHAFEE[1,3], R. L. BUCKNER[2,1,3,4,5], B. FISCHL[6,7,8]

Imaging, Boston, MA; [5]Psychiatry, Massachusetts Gen. Hosp., Boston, MA; [6]Radiology, Massachusetts Gen. Hospital/Harvard Med. Sch., Boston, MA; [7]Computer Sci. and Artificial Intelligence Lab., MIT, Cambridge, MA; [8]Div. of Hlth. Sci. and Technol., Harvard-MIT, Cambridge, MA

Abstract: The myelination pattern of the human cerebral gray matter has been investigated using MR techniques with results agreeing well with ex-vivo methods based on myelin staining. Recently Glasser & Van Essen (2011) presented their results for standard 1 mm isotropic 3T scanner protocols. At this resolution, a single voxel may contain both gray and white matter, as well as cerebrospinal fluid in the thinnest parts of the cortex (for example, V1). This motivated us to add partial volume correction to their technique. Our method estimates the intensities of different tissue classes at the boundaries, potentially allowing for a more precise myelin content measurement. We applied the method to a large cohort of subjects (N = 1500, 20.9 +/- 2.8 years, 610 males) to obtain group-averaged gray matter myelination maps from the ratio of raw T1- and T2-weighted images of each subject as well as bias-field corrected T1- and T2-weighted images independently. The Freesurfer pipeline was used to generate surfaces and estimate T1- and T2-weighted intensities in the gray matter layer. These data were then mapped to a common template using surface-based registration. Using 62 subjects that were scanned twice we investigated the reliability of the individual myelin maps. We found the primary sensory areas to be heavily myelinated and the association areas to be less myelinated, consistent with previous results. We further observed that partial volume corrections affect the gray matter myelination in the sulci more than in the gyri likely due to the interaction of voxel geometry and cortical geometry. Analysis of the test-retest data suggests improved reliability particularly in the prefrontal cortex when using partial volume correction. Since the cortical gray matter layer sends and receives projections from subcortical areas, next we applied our technique to investigate the covariation of cortical myelin map with subcortical volumes. After controlling for age, gender, handedness and intra-cranial volume, the most significant and reproducible correlation ($r \sim 0.15$) was found between visual cortex myelination and the volume of the thalamus. Additionally, we found a weaker correlation ($r \sim 0.11$) between amygdala volume and parahippocampal cortex myelination. These results are consistent with known anatomical projections.

Title: Bilateral white matter microstructure accounts for individual differences in adult rapid naming and reading abilities

Authors: *A. C. ZUMBERGE[1], J. L. BRUNO[2], B. D. MCCANDLISS[3], Z. LU[1], F. R. MANIS[1]
[1]Psychology, USC, Los Angeles, CA; [2]Psychiatry and Behavioral Sci., Stanford Univ., Stanford, CA; [3]Psychology, Vanderbilt Univ., Nashville, TN

Abstract: Mounting evidence from diffusion tensor imaging (DTI) studies suggests that the integrity of white matter tracts varies across individuals and may be related to specific cognitive skills. The current study sought to examine the relationship between adult reading ability and temporo-parietal white matter microstructure. Whole-brain DTI images were collected from 68 adults with varying reading ability, and white matter structures were selected on an individual basis using a semi-automatic segmenting tool. Consistent with findings from the developmental literature, fractional anisotropy in the superior corona radiata (SCR) was positively correlated with multiple measures of adult reading and language abilities, including rapid picture naming, timed single word reading, and passage comprehension. In contrast to the developmental literature, correlations were observed in both left and right SCR, suggesting that right hemisphere microstructure may play an increasingly important role in reading in adulthood and vary systematically with reading skill. Further, regression analyses revealed that after accounting for rapid picture naming scores, SCR microstructure no longer explained a significant proportion of the variance in either reading measure. Results indicate that SCR may underlie a common variable like verbal processing speed, which is in line with the hypothesis that the integrity of white matter fibers that transfer information between cortical “nodes” of language processing, in part, determines the speed and efficiency with which an individual computes linguistic stimuli.

Title: Neural correlates of political ideology: Individual differences in liberalism-conservatism are reflected in the brain's intrinsic functional organization

Authors: *C. L. COX[1], J. T. JOST[2], F. CASTELLANOS[1,3], M. P. MILHAM[4,3], C. KELLY[1], J. J. VAN BAVEL[2]
[1]NYU Child Study Ctr., New York, NY; [2]Dept. of Psychology, New York Univ., New York, NY; [3]Nathan Kline Inst. for Psychiatric Res., Orangeburg, NY; [4]Ctr. for the Developing Brain, Child Mind Inst., New York, NY

Abstract: Though long thought to arise from differences in beliefs about human nature and personal experiences, recent research suggests that individual differences in political ideology (PI; liberalism/conservatism) are associated with more basic cognitive and motivational orientations (Jost et al., 2003; Oxley et al., 2008). Here, we examined whether individual differences in PI are associated with the intrinsic functional architecture of the brain.
Previous research has shown that PI is associated with both the structure and function of the dorsal anterior cingulate cortex (dACC). Liberalism is associated with increased gray matter (Kanai et al., 2011) and increased conflict-related processing in dACC (Amodio et al., 2007). The dACC is part of a network of regions, including the insula and striatum, that processes emotionally significant stimuli (Seeley et al., 2007). Regions within this network exhibit correlated low-frequency fluctuations in the resting state fMRI (R-fMRI) signal, quantified using intrinsic functional connectivity (iFC) methods. We investigated the relationship between the iFC of the dACC and individual differences in self-reported PI.
Forty-seven adults (mean age=23.7 yrs; 33 male) completed a 6 min R-fMRI scan and a self-

report questionnaire assessing PI. After standard preprocessing, the timeseries from regions of interest in bilateral dACC (Kanai et al., 2011) was extracted for each individual and correlated with every other voxel in the brain. PI scores were entered as a covariate in group analyses, producing maps of significant PI-iFC relationships ($Z>2.3$, $p<0.05$, corrected).
PI was significantly negatively related to iFC between the dACC and the right insula and putamen. Greater liberalism was associated with increased, while greater conservatism was associated with decreased iFC between these regions. A similar pattern was observed with system justification scores ($r=-0.42$, $p<0.05$), the tendency to believe that existing social and economic institutions and arrangements are fair and legitimate (Kay & Jost, 2003).
Our results provide the first evidence that political ideology is related, not only to task-evoked responses in the dACC itself, but to the intrinsic communication among regions within a broader functional network. These findings support the idea that basic cognitive orientations, such as preference for social stability/order over change (system justification), and the need to manage uncertainty and sensitivity to threat, all strongly associated with PI, are also reflected in the strength of connection among brain regions implicated in processing this information, even in the absence of any explicit task.

Title: Myelination differences in preterm infants and toddlers

Authors: *N. E. WASKIEWICZ[1], D. C. DEAN, III[1], J. O'MUIRCHEARTAIGH[1,3], H. DIRKS[1], K. LEHMAN[1], B. A. JERSKEY[1,2], S. C. DEONI[1]
[1]Advanced Baby Imaging Lab, Sch. of Engin., [2]Dept. of Psychiatry & Human Behavior, Brown Univ., Providence, RI; [3]Dept. of Neuroimaging, King's College, Inst. of Psychiatry, London, United Kingdom

Abstract: Introduction: Nearly 12.7 percent (more than 500,000) of pregnancies within the United States result in premature birth, while the rate of premature childbirths has been on the rise since the early 1990's (Martin, J.A. et al., 2007). Fortunately, the survival of these children has dramatically improved with advances in medical care and technology, however, 'preterms' are still faced with a significant risk of having neurodevelopmental deficits (Panigrahy et al., 2012). The maturation of myelinated white matter is fundamental to brain development; establishing coordinated communication pathways among unified neural systems. It is unknown, however, if this process is disrupted or altered in children born premature. Deoni et al. have investigated myelin maturation in healthy, typically developing children using an MRI-based myelin-specific imaging technique, multi-component single pulse observation of T1 and T2 (mcDESPOT; Deoni et al., 2011). This data provides a salient baseline for identifying myelination differences in children born preterm.
Objective: To investigate myelination differences between children born premature and those born at full term, 8 preterm (mean age=778.125 days, corrected to 40 week gestation [age range=187-1716 days], mean gestation=34 weeks) and 32 full term (mean age=794.125 days, [age range=179-1552 days], mean gestation=39.25 weeks) children were scanned and compared against data from children born at full term.
Methods: mcDESPOT-derived myelin water fraction (MWF) maps were acquired during natural, non-sedated sleep (Deoni et. al., 2011) and aligned to a common study template using the Advanced Normalization Tools (ANTs; Avants et al., 2008) package. Significant myelin content differences over time ($p<0.025$) between the preterm and term children were examined by calculating cluster-corrected voxel-wise t-statistics using FMRIB Software Library's (FSL) randomise tool.
Results: Widespread myelination deficiencies in the preterm group were found in areas that included bilateral frontal and parietal lobes, cingulate gyrus, right lingual gyrus, and left amygdala. These findings are consistent with previous imaging studies that have investigated differences between preterm and term children (Liu et al., 2012).
Conclusions: Presented results illustrate significant myelin-content differences between preterm and full term children. Although preliminary, these results suggest that myelination is in fact altered in preterm children and possibly underlies neurodevelopmental deficits associated with premature birth.

Title: ADRA2b polymorphism influences attentional capture by emotional material and subsequent emotionally enhanced memory

Authors: *R. M. TODD[1], A. ROBERTSON[1], D. MUELLER[2], A. K. ANDERSON[1]
[1]Psychology, Univ. of Toronto, Toronto, ON, Canada; [2]Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada

Abstract: Recent research has revealed that genetic variation associated with altered neurotransmission is linked to individual differences in the capacity for emotional memory. Specifically, a deletion variant of the ADRA2b gene, which influences norepinephrine (NE) activity in the amygdala, has been associated with emotional enhancement of memory as well as susceptibility to intrusive memory following trauma. Yet the distinct processes of emotional memory formation influenced by ADRA2b are not yet known. The goal of the present study was to test whether ADRA2b influences rapid encoding or more extended post-encoding processes, and to measure interactions with other genes at distinct phases of memory formation.
Saliva samples were collected from 224 young Caucasian adults (151 female) with no history of psychopathology. Effects of emotional salience on rapid attentional capture at encoding were measured with an attentional blink task. Participants also viewed arousing and neutral pictures, and recognition memory was measured one week later. Control measures of sex, neuroticism, working memory, and history of childhood abuse were also included. Polymorphisms of interest were ADRA2b, as well as the 5HTTLPR serotonin transporter gene (short vs. long) and a valine to methionine single-nucleotide polymorphism (SNP) in the COMT gene coding the catechol-O-methyl transferase enzyme that metabolizes prefrontal dopamine (DA).
Results showed that ADRA2b genotype predicted the influence of emotional salience on rapid encoding processes measured by the attentional blink after controlling for the influence of other genes and control variables (e.g., APOE, KIBRA). ADRA2b also influenced emotional enhancement of memory one week later in interaction with COMT genotype, with deletion carriers who had two copies of the COMT met allele showing greatest emotional enhancement of memory. History of childhood abuse also influenced emotionally enhanced memory but its contribution was unique, revealing no evidence of a gene-environment interaction. Overall, results show novel evidence for the influence of ADRA2b on the effects of emotion on rapid attentional capture. Effects on later recognition memory were more complex, suggesting that over longer-term consolidation processes, genetic variation linked to NE and DA processes interact to influence emotional memory.

Title: The retention rate and nature of Highly Superior Autobiographical Memories over time.

Authors: *A. K. LEPORT, J. L. MCGAUGH, C. E. L. STARK
Neurobio. and Behavior, Univ. of California Irvine, Irvine, CA

Abstract: We have recently documented a new memory ability known as Highly Superior Autobiographical Memory (HSAM). HSAM subjects have a remarkable ability to recall accurately a vast quantity of autobiographical details from autobiographical events that span across their lifetime. While it is clear their behavior is exceptional, there are many open questions concerning the qualities of their memories. The current study takes a step further by quantifying the number of details an HSAM participant can recall from very recent to very remote autobiographical memories and qualifying the elements that compose these memories. Both HSAM and age- and sex-matched controls were instructed to recall as many details as could be remembered from each of the past seven days as well as from each of the same seven days one and ten years ago (21 specific days probed). Comparisons between the two groups indicated overall similar levels of details recalled from one-day and one-week-old memories, but HSAM participants significantly outperformed controls at the one-year and ten-year-old time periods. This finding suggests that at least part of their ability stems from enhanced retention mechanisms. In addition, we will discuss results based on the Autobiographical Interview (Levine et al. 2002) scoring technique to analyze qualitative differences in the kinds of details retrieved.

Title: Impact of the KIBRA polymorphism on autobiographical memory

Authors: *D. J. PALOMBO, R. S. C. AMARAL, B. LEVINE
Univ. of Toronto, Toronto, ON, Canada

Abstract: Episodic memory refers to the recollection of temporally and spatially bound contextual details of an experience, which could include autobiographical episodes or information learned in a laboratory setting. Recently, the KIBRA gene has been associated with episodic memory performance in a replicated genome-wide association study (e.g, Papassotiropoulos et al., 2006). This gene is highly expressed in the hippocampus and has been linked to synaptic plasticity. Carriers of a (T to C) SNP in this gene show enhanced episodic memory performance in comparison to non-carriers. Although this association has been replicated in subsequent studies, conflicting results have also been found. Further, this research has focused on laboratory material to probe episodic memory. Employing more naturalistic autobiographical stimuli, with a greater reliance on memory vividness, may provide a more ecologically valid measure of this phenotype. In the present study, we examined episodic memory for laboratory and autobiographical stimuli in a large sample of healthy adults in relation to KIBRA genotype. Next, in a subset of these participants, magnetic resonance imaging (MRI) was employed to explore genotype-dependent differences in brain volume within the subfields of the hippocampus and in BOLD response associated with episodic and autobiographical memory tasks.

Title: Individual threat bias behavior is mediated by Limbic coupling with either lateral or medial PFC

Authors: T. LIN[1], S. VAISVASER[1], R. ADMON[1], D. PINE[2], D. CHARNEY[3], I. WALD[1], Y. BAR-HAIM[1], *T. HENDLER[4]
[1]Tel Aviv Univ., Tel Aviv, Israel; [2]The Inst. of Mental Hlth., Rockville, MD; [3]Mount Sinai Sch. of Natl. Med., New York, NY; [4]Tel-Aviv Sourasky Med. Ctr., Tel-Aviv, Israel

Abstract: Background
Individuals differ in the extent to which they selectively attend to threat. Some exhibit high threat vigilance and others show threat avoidance, perhaps in an attempt to down regulate emotional responses to threats. Thus, allocation of attention to potential threats in the environment might have a central role in emotion regulation and through that in effective coping with threat. Assuming that lateral and medial PFC are involved in emotional regulation via attention allocation and/or appraisal, we hypothesized that functional connectivity of limbic areas with PFC regions would characterize different bias tendencies as measured during performance on a classic threat-attention task.
Methods
54 healthy males (mean age = 19) participated in an event related fMRI study using the dot-probe attention task with angry faces as the threat signals and neutral faces as the safe signals. Participants were allocated to one of two groups based on their attentional threat bias scores: threat avoidance (AVO, N=25) threat vigilance (VIG, N=29).
Results
Whole brain contrast to the threat signal revealed activation in key limbic structures involved in the reaction to threat stimuli: the periaqueductal gray matter (PAG) and left hippocampus. This regional threat activation though was more pronounced in the AVO group. Between-groups comparisons of functional connectivity revealed greater coupling of the PAG and the hippocampus with the dorso- and ventro-LPFC in the AVO group, and greater coupling of the hippocampus with the ventro-MPFC in the VIG group. Further network analysis using Dynamic Causal Modeling (DCM) indicated that these group differences may be attributable to a lack of PAG regulation by the ventro-LPFC resulting in higher medial-PFC connectivity with the hippocampus in the VIG group.
Conclusions
Our results show that threat bias patterns of avoidance and vigilance involve co-activation of major limbic areas with the Lateral or Medial PFC, respectively. Together with pervious evidence of associations between threat-related biases and psychiatric symptoms of anxiety and trauma, our finding point to the possibility of individually-tailored therapeutic interventions that take into account the brain markers of these personal biased behaviors.

Title: Pulse induction in pseudorandom sequences measured with pulse attribution and tapping rate

Authors: *M. J. VELASCO, E. LARGE
Ctr. for Complex Systems, Florida Atlantic Univ., Boca Raton, FL

Abstract: The question of pulse perception involves asking, for any given rhythmic sequence, whether the sequence has a pulse, and if so what is its frequency. Experimentally, these issues are usually addressed separately, by asking participants to provide judgments of isochrony for jittered sequences (pulse attribution) or by asking participants to tap at a perceived pulse rate for rhythmic patterns (pulse finding). In this experiment, the stimuli were isochronous sequences modified with varying levels of Kolakoski jitter. Levels of jitter ranged from small to large and were roved randomly. In separate blocks, participants were asked to provide pulse attribution judgments and to tap at the pulse rate. For small levels of jitter, pulse attribution ratings were high and participants tapped periodically at the mean sequence rate. For intermediate levels of jitter, pulse attribution ratings dropped and tapping variance increased. At certain high levels of jitter, pulse attribution ratings increased and participants entrained at a new tapping rate. Spectral energy peaks predicted mean tapping rate and stronger peaks corresponded to higher pulse attribution ratings, consistent with a neural resonance model of pulse perception. These results may lead to a better understanding of pulse perception in irregular or randomized sequences.

Title: Duration tuning in the human striatum

Authors: *M. J. HAYASHI[1,2], R. KANAI[2], T. DITYE[2], S. CARLSON[1,3,4], V. WALSH[2]
[1]Inst. of Biomedicine/Physiology, Univ. of Helsinki, Helsinki, Finland; [2]Inst. of Cognitive Neuroscience, Univ. Col. London, London, United Kingdom; [3]O. V. Lounasmaa Laboratory, Aalto Univ. Sch. of Sci., Espoo, Finland; [4]Med. School, Univ. of Tampere, Tampere, Finland

Abstract: Temporal processing is crucial in many aspects of perception and behavior. Several theoretical models of timing, such as labeled-line models and population clock models, assume that elapsed time is represented by a population of neurons that fires selectively to their preferred duration (see Buonomano and Laje, 2010). Moreover, a recent behavioral study in humans suggested a channel-based processing of time intervals ("duration channels") based on the finding that sensory adaptation to a duration induces distortions in the perceived durations across a limited range of stimulus durations centered on the adapted duration (Heron et al., 2012). Despite these theoretical and behavioral studies, however, neural representations of duration tuning have not been identified to date. Here, we present evidence of temporal tuning in the human striatum by an fMRI-adaptation paradigm. In the experiment, participants (n=18) were asked to perform a duration discrimination task or a shape discrimination task (same or different judgments) depending on the instruction given at the beginning of each block consisted of five trials. On each trial, a reference (adaptation) stimulus was presented for 400 ms followed by a test stimulus, presented for a variable duration (either 160 (far-), 280 (close-), 400 (same), 520 (close+), and 640 (far+) ms). The combinations of stimulus shapes (a rectangle / triangle) for the reference and test stimuli were also varied to equate the stimuli for the duration and shape tasks. In a whole brain analysis, we examined which brain regions showed graded adaptation effects according to the duration difference from the reference stimulus (i.e., same < close+, close- < far+, far-). Only the left striatum exhibited suppression of the BOLD signal to the repetition of the same duration ($p < .05$ FWE corrected at cluster level, $p < .001$ uncorrected at voxel level). Moreover, the values of regression coefficients (beta) of the duration-adaptation in the left striatum correlated significantly with the individual differences in the duration discrimination performance (d') ($r = .58$, $p < .05$). The control condition (the shape discrimination task) confirmed that the adaptation effect observed in the striatum was specific to the duration task, and did not generalize to repetition of shape. These results indicate that the human left striatum is tuned to duration, and plays a significant role in human time perception. Our study demonstrates, for the first time, the neural representations of duration in the human brain.

Title: Distinction between neural correlates for temporal order and simultaneity judgments

Authors: *M. MIYAZAKI[1], H. KADOTA[2], K. S. MATSUZAKI[2], S. TAKEUCHI[3], H. SEKIGUCHI[3], T. KOCHIYAMA[4]
[1]Res. Inst. for Time Studies, Yamaguchi Univ., Yamaguchi, Japan; [2]Kochi Univ. of Technol., Kami, Japan; [3]Jobu Univ., Isesaki, Japan; [4]Kyoto Univ., Kyoto, Japan

Abstract: Perceiving temporal relations between external events is one of the key processes for coordinating human cognition and behavior. Temporal order judgment (TOJ) and simultaneity judgment (SJ) have been widely used in psychophysical studies on this perceptual process. TOJ and SJ provide two identical psychometric parameters: a point of subjective simultaneity and temporal resolution for judgment. Experimental results for both tasks are often not distinguished from each other in research discussions. However, a theoretical model suggests that TOJ and SJ are two distinct systems (Jakowski 1991). In fact, there are psychophysical distinctions between TOJ and SJ. For example, the cross-hand deficit of tactile TOJ (Yamamoto & Kitazawa 2001, Shore et al. 2002) has not been observed in SJ (Axelrod 1968). In this study, we used fMRI to identify the differences in neural correlates between TOJ and SJ. Sixteen healthy subjects (8 male, 8 female, all right-handed) participated in our experiment. During fMRI recording, the subjects performed TOJ and SJ with two tactile stimuli across both hands. The stimuli and the stimulus intervals were identical in both tasks. The response ratios were even between earlier right and left in TOJ and between simultaneous and non-simultaneous in SJ, and no difference was found between the tasks. Brain imaging data showed that SJ activated the left anterior insula and surrounding areas more than TOJ activation. Compared to SJ, greater activation by TOJ was found in the left ventral premotor cortex and the superior parietal cortex extending to the inferior parietal cortex, as well as in the bilateral dorsal premotor cortexes and thalamus. Additionally, the right cerebellum was activated more strongly in TOJ than in SJ at the uncorrected significance level. The activated areas specific to TOJ are known as motor-control-related areas. Our findings suggest that somatosensory TOJ shares neural correlates with motor control, which can account for recent psychophysical findings regarding temporal judgment [e.g., a cross-hand deficit in TOJ occurs in uncrossed hands when subjects are planning to cross their hands (Hermosillo et al. 2011)].

Title: Predictable visual stimuli are perceived earlier than unpredictable events

Authors: *B. WIRXEL, A. LINDNER
Hertie Inst., Tuebingen, Germany

Abstract: How is it possible that we timely react to visual events despite the significant processing delays within the visual system? This delay is estimated to be already about 100ms in higher visual areas, a delay which is relevant if one needs to initiate fast reactions, such as catching a ball in flight or initiating escape. To compensate delays the brain employs predictive mechanisms. An example is the internal forward model which allows the motor system to predict an upcoming sensory state and thus to react even before sensory feedback is available. It is quite likely that - apart from this and other predictive mechanisms on the motor level - purely perceptual predictions could also contribute to delay compensation. Yet, to our knowledge, there is no compelling evidence for delay compensation on a strictly perceptual level. Hence, we asked whether predictability of a visual stimulus affects the time of perceived stimulus onset. Specifically, we hypothesized that predictable visual stimuli have an earlier perceived onset compared to non-predictable stimuli.
We tested our hypothesis in a psychophysical experiment, in which we initially screened 23 subjects in a dual task that engaged temporal interval judgements. In the middle of a black screen streams of individual letters were presented. Each letter was presented for 300ms with a 1000ms default interval between letters. The sequence of letters was either in alphabetic order and thus predictable or, alternatively, the last letter of a sequence was chosen at random and thus not predictable. In each trial subjects had to indicate whether or not the last letter agreed with the alphabetic order. Moreover, subjects had to estimate whether the duration of the last interval, which was of varying length, was either longer or shorter as compared to the preceding intervals of 1000ms duration. Varying the length of the last interval allowed us to estimate the point of subjective equivalence (PSE) between intervals. As we expected predictable letters to be perceived earlier, the PSE should be larger in predictable sequences than the PSE in non-predictable ones. Since our experiment required precise timing we applied rather strict exclusion criteria to both trials and subjects. For the six subjects that survived these criteria there was a significant shift of the PSE towards larger values for predictable sequences (median shift: 54.99 ms; $p=0.0313$). Hence, our findings show that predictable visual stimuli are in fact perceived earlier than non-predictable ones. This suggests that even the perceptual system is compensating

for delays in sensory information processing, allowing us to establish a timely percept of our environment.

Title: Neural substrates of interval timing in the human brain

Authors: *H. SOHN, S.-H. LEE
Dept. of Brain & Cognitive Sci., Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: A vast volume of psychophysical studies on interval timing (IT) point to its omnibus involvement in an extensive repertoire of sensory, executive, and motor behaviors, without any sensory channels dedicated to encoding of time intervals. This ubiquitous association of IT with other cognitive events makes it difficult to elucidate neural underpinnings of IT because neural responses pertaining to IT and those non-IT events are intimately intermingled. Recently, we developed an implicit IT task, in which subjects watched an object move at a constant speed and become invisible unpredictably, and guessed the arrival time of the invisible motion at a specified position. Exploiting the fact that stimuli are absent during the period of interval estimation, we adapted this task to fMRI experiments to explore cortical mechanisms that substantiate IT in humans. Subjects performed the task on three reference time intervals (7, 10, 16 s), which were defined (T=Dim/Vvm) on a trial-by-trial basis by variable combinations of a speed of visible motion (Vvm) and a distance of invisible motion (Dim). Trials of seamless visible motion, where interval timing was thus not required, were also included to control for cortical responses due to motor planning and execution. The distributions of reaction times exhibited the scalar property - the constant coefficient of variation across time intervals, confirming that they provided measurements of interval timing. The areas MT and superior parietal lobule (SPL), likely a human homologue of the macaque LIP, were both activated during the period visible motion, consistent with their well-known responsitivity to moving stimuli. Unlike MT, however, SPL remained active during the ensuing period of invisible motion, along

with other motor-associated regions including putamen and cerebellum. The SPL's sustained activity overarching the visible and invisible motion periods may be construed as (i) the cortical activity of accessing the spatiotemporal information available in sensory areas, (ii) the neural accumulation of elapsed time at timescale of seconds as suggested by the pacemaker-accumulator model, or, alternatively, (iii) a neural correlate of the hazard rate of elapsed time, in line with previous findings in the primate brain.

Title: Directional flow of TMS-induced phase perturbation across low frequency neural synchrony networks in the resting state

Authors: *M. KAWASAKI[1], Y. MIZUNO[1,2], K. KITAJO[1,2,3]
[1]Rhythm-Based Brain Computation Unit, RIKEN BSI-TOYOTA Collaboration Ctr., Saitama, Japan; [2]Tokyo Univ. of Agr. and Technol., Tokyo, Japan; [3]PRESTO, Japan Sci. and Technol. Agency (JST), Saitama, Japan

Abstract: Even in a resting state without any input of sensory stimuli, our brain is active and constructs a default mode network (Raichle, et al., 2001). Such networks connect many brain regions including sensory areas, motor areas and frontal areas. However there is no explicit consensus about causal and directional information flow (i.e. bottom-up, top-down) within the default mode network. To address the issue, it is particularly useful to elucidate the causal perturbation of electroencephalograph (EEG) oscillations among specific brain regions by a transcranial magnetic stimulation (TMS). TMS is able to reset the phase of ongoing cortical oscillations and the phase resetting propagates from the stimulated area to other brain regions. Here, we applied single-pulse TMS to resting-state brains during 67-channel scalp EEG measurements and evaluated dynamic patterns of changes in EEG oscillations. Ten right-handed participants were required to rest with their eyes closed and completed 20 sessions; 4 TMS intensities (95, 80, 65, and 50%; 100% means motor thresholds) X 5 TMS-target locations (frontal (Fz), left motor (C3), right motor (C4), visual (Oz) and sham). To estitame the time-frequency patterns, current source density analysis was first applied and wavelet analysis was then performed for the EEG data which was preprocessed to extract the TMS and ocular artifacts

by a linear interpolation and an independent component analysis, respectively.
The TMS-induced increase in phase-locking values, which estimates phase resetting of the low-frequency EEG oscillations around the TMS target locations. In the visual-area targeted TMS, phase resetting of the theta (about 3Hz) and alpha (about 10Hz) oscillations transmitted from the visual areas to the motor areas (especially left motor area) via the frontal areas. Moreover, in the TMS to the frontal and right motor areas, the theta and alpha phase resetting converged to the left motor areas. Such phase reset transmissions decreased and disappeared as the TMS intensities decreased and the decrements were also found under the sham conditions. These results suggested the existence of potential bottom-up networks from the sensory regions to the output regions (i.e. motor area) in the resting state.

Title: The role of the basal ganglia in rhythmic entrainment and musical emotions

Authors: *W. J. TROST[1,2], D. SCHÖN[3], C. LABBÉ[1], S. FRÜHHOLZ[1], D. GRANDJEAN[1], S. PICHON[2], P. VUILLEUMIER[2]

Abstract: Rhythmic entrainment is thought to contribute to emotion induction in response to music and may impact on motor as well as attentional performance. Furthermore, the basal ganglia (BG) are known to be both sensitive to musical rhythms and to be recruited during the processing of positive musical emotions. We investigated the neural mechanisms of rhythmic entrainment by musical meter and its modulation by aesthetic appreciation with the use of functional magnetic resonance imaging (fMRI). In particular we tested whether pleasant music would lead to stronger entrainment effects and asked whether such effects might involve BG. We designed an fMRI study where participants (n = 18) listened to piano music while performing a visual speeded response task. The task consisted of detecting visual cues that appeared time locked to either a strong or a weak beat of the musical meter. Each musical piece was presented in both a consonant and a dissonant version. Behavioral results showed a main effect of meter and a main effect of consonance on reaction times but no interaction. fMRI results showed a

main effect of meter in bilateral caudate nucleus, whereas a main effect of consonance was found in an attentional networks including parietal regions as well as motor areas. A selective interaction between meter and consonance was found in the caudate body and right anterior insula. These results show that the caudate nucleus is sensitive to subtle differences of rhythmic expectancies induced by the musical meter, an effect that is predominant during dissonant music. Behavioral and fMRI results together suggest that consonant music leads to a global broadening of attentional resources, whereas dissonant music may restrict attention on the rhythmical structure and make the temporal organisation of the music more salient, leading to stronger involvement of BG.

Title: Spectro-temporal analysis of auditory processing in young infants: Relationships between event related oscillations (EROs) and evoked potentials

Authors: *G. MUSACCHIA[1], N. CHOUDHURY[2,1], S. ORTIZ-MANTILLA[1], T. REALPE-BONILLA[1], A. A. BENASICH[1]
[1]Ctr. for Mol. & Behavioral Neurosci., Rutgers Univ., Newark, NJ; [2]Ramapo Col. of New Jersey, Mahwah, NJ

Abstract: The averaged event-related potential (ERP) has been successfully used to track auditory processing development from early infancy to adulthood. New and ongoing studies suggest that analysis of both time and frequency components of single trial ERPs can add new knowledge about underlying neural mechanisms. The development of age-appropriate magnetic resonance imaging (MRI) models also facilitates more accurate source localization of ERPs at this early age. Thus, our aim is to localize and characterize the spectro-temporal dynamics of ERPs recorded to complex tone pairs in typically developing infants. A group of typical 4 month olds were fitted with a 128 scalp electrode net while seated in the parent's lap and silently

entertained. Free field 800 Hz tones with a duration of 70 ms were presented in pairs with either a 70 or 300 ms inter-stimulus interval (ISI), and 915 or 1140 ms stimulus onset asynchrony between pairs, respectively. After visual inspection and artifact removal, individual ERPs were averaged (EEGLAB, ERPLAB). Co-registered, age-appropriate MRIs were used to model a two-dipole source solution for the grand average ERP and each individual (BESA, Inc.). Within subject tests showed that the latency of the first positive deflection was higher (transaxial) and faster in the right hemisphere dipole than the left for the 300 ms ISI condition. This asymmetry lessened in the 70 ms ISI condition. Spectro-temporal analyses were conducted on the source waveform single trials using a 1-90 Hz frequency band range. EROs were calculated for each individual over time, relative to pre-stimulus baseline (BESA, Inc.), and subsequently pooled (MATLAB). Grand average and individual ERO spectra exhibited a 1/f characteristic, with peaks of activity in ranges of 2-8, 15-30, and 38-55 Hz. Temporal modulation of the EROs coincided with stimulus onset timing in both the 70 and 300 ms ISI conditions. Overall, an oscillatory hierarchy was observed with the EROs. In particular, desynchronization in the 17-30 Hz range was strongly anti-correlated with synchronization in the 38-53 Hz range. Linear regression showed that ERO timing and strength in these two bands strongly predicted the slope of the first positive-to-negative deflection of the ERP. These data show that the interplay of oscillations contribute to the initial stages of auditory processing in the infant brain. Because the timing of these EROs precede stimulus onset, we suggest that they reflect neural mechanisms of phase-coupled entrainment that facilitate sensory processing. Future data are needed to determine developmental changes in this mechanism and whether auditory training impacts this relationship.

Title: Hand movements induce time compression for tactile stimuli

Authors: *A. TOMASSINI[1], M. GORI[1], G. SANDINI[1], M. MORRONE[1,2,3]
[1]Robotics, Brain and Cognitive Sci., Fondazione Inst. Italiano Di Tecnologia, Genova, Italy; [2]Dept. of Physiological Sci., Univ. di Pisa, Pisa, Italy; [3]Scientific Inst. Stella Maris, Calambrone, Pisa, Italy

Abstract: Saccadic eye movements cause compression of visual space towards the saccadic target, and also a compression of time [Morrone et al., 2005; Binda et al., 2009], both phenomena thought to be related to the problem of maintaining saccadic stability. Interestingly, similar phenomena occur around the time of hand movements, when brief tactile stimuli are systematically mislocalized in the direction of the movement [Dassonville, 1995; Watanabe et al., 2009; Maij et al., 2011]. In this study we measured whether hand movements also cause an alteration of the perceived timing of the touch signals. Participants compared the temporal separation between two pairs of tactile taps delivered to the right index fingertip while moving their hand. Each trial began with the presentation of the first pair of taps (the probe) separated by a variable time interval. After a variable pause an auditory tone cued participants to move their right hand as fast as possible along a track. At variable delays from the sound presentation, the second pair of taps (the test) was delivered with a fixed onset asynchrony of 150 ms. When the tactile stimuli were presented close to the onset of hand movement perceived temporal separation was strongly reduced. The time compression began approximately 200 ms before movement onset, it increased up to 30 % until just before the hand started moving and continued until the end of the movement. The results suggest that, as for vision, tactile time intervals are strongly compressed around the time of hand movements. As for vision, the mislocalizations of time and space of touch stimuli may be consequences of a mechanism attempting to achieve perceptual stability.

Title: Functional connectivity dynamics across the entire brain space in health and disease: Conceptual perspective

Authors: *U. RIBARY[1,2], S. DOESBURG[3,4], L. WARD[2]
[1]Behavioral and Cognitive Neurosci. Institute, Simon Fraser Univ. (SFU), Burnaby, BC, Canada; [2]Univ. of British Columbia (UBC), Vancouver, BC, Canada; [3]Hosp. for SickKids, Toronto, ON, Canada; [4]Univ. of Toronto, Toronto, ON, Canada

Abstract: Recently, there has been increased interest in understanding brain networks and their connectivity , especially regarding structural and functional connectivity at the cortical level. Functional connectivity dynamics and particularly thalamo-cortical interactions are as yet insufficiently integrated with our knowledge of large-scale connectivity and regional function. An important question, yet to be answered in detail, is how typical and atypical cognitive functions and consciousness are temporally generated across the entire brain space. The challenge in current dynamic brain imaging is to analyze the detailed communication or connectivity dynamics across five dimensions, within 3D space across oscillatory frequency and time, and to quantify in detail the relation of these dynamics to typical and atypical cognition and consciousness.
Over the past two decades, MEG/EEG work has been reported on the dynamics of functional connectivity, particularly emphasizing that synchronization of neuronal oscillations both within and between brain regions is an important mechanism mediating formation and communication within distributed neural networks. In particular, there is a large and accumulating body of evidence that task-dependent gamma-band activations and connectivity correlated across frequency and time play a vital role in most cognitive brain functions and represent a critical component to the biological basis of consciousness.
We present a conceptual overview of oscillatory network dynamics and its implications for how brain imaging technologies can be further used to probe fully intact structural, functional and temporal connectivity in thalamo-cortical, cortico-cortical, and cortico-thalamic circuits to better understand typical and atypical cognition and consciousness.

Title: Time-dilation and time-contraction with accelerating and decelerating dynamic visual stimuli.

Authors: *N. BINETTI[1,2,3], F. LECCE[2,3], F. DORICCHI[2,3]
[1]Inst. of Cognitive Neurosci., London, United Kingdom; [2]Univ. degli Studi di Roma "La Sapienza", Rome, Italy; [3]Fondazione Santa Lucia IRCCS, Rome, Italy

Abstract: Several studies show that visual stimuli traveling at higher velocities are overestimated with respect to slower, or stationary, stimuli of equivalent physical duration. This effect - "time dilation" (Brown, 1995; Kanai et al., 2006; Kaneko & Murakami, 2009)- relates more in general to several accounts highlighting a quantitative relationship between the number of changes a stimulus undergoes in a given time frame and its perceived duration. "Change-based" models of timing predict that faster stimuli, subject to a greater number of changes in space, lead to overestimated durations of displacement. Here we provide evidence of a new illusory effect, in which the apparent duration of a sensory event is affected by the way a constant number of changes are delivered in time, or in time and space. Participants judged accelerating and decelerating sequences of stationary flickering stimuli (exp 1 & 3), and accelerating and decelerating horizontally drifting visual stimuli (exp 2) on the fronto-parallel plane. Acceleration and deceleration were achieved by irregular sequencing of events in time (anisochronous flicker rate), or irregular sequencing of events in time and space (anisochronous and/or anisometric drift). Accelerating and decelerating sequences lead to opposite duration biases (under-estimation and over-estimation errors, respectively). This bias was observed in both subsecond (760 ms) and suprasecond ranges (1900 ms). Throughout all experiments, the crucial manipulation was that the mean number of changes in time (mean Hz of flickering stimuli), and mean number of changes in space/time (mean velocity of horizontally drifting stimuli) was always constant: subjects could not rely on a change based criterion to estimate stimulus duration. Change-based models therefore cannot account for such results. Overall, these data highlight how the spatio-temporal evolution of dynamic visual events, asides the total number of changes they are subject to, affect the perceived amount of time they require to unfold.

Title: Phase shifts of low frequency oscillations in sensory cortices correlate with perceived shifts in temporal order

Authors: *A. KÖSEM[1,2,3], A. GRAMFORT[4,5], V. VAN WASSENHOVE[1,2,3]
[1]INSERM-CEA Cognitive Neuroimaging Unit, Gif-sur-Yvette, France; [2]CEA, DSV/I2BM, NeuroSpin Ctr., Gif-sur-Yvette, France; [3]Univ. Paris-Sud, Cognitive Neuroimaging Unit, Gif-sur-Yvette, France; [4]INRIA, Parietal team, Saclay, France; [5]LNAO/NeuroSpin, CEA Saclay, Gif-sur-Yvette, France

Abstract: Many ecologically relevant events (e.g. speech, danse/ music…) are multisensory and present temporal regularities that have been shown to influence the detection and perceived timing of events. Recent neurophysiological findings provide strong support for the role of oscillatory entrainment in the modulation of visual and auditory stimulus detection after rhythmic stimulation. Neural entrainment has thus been hypothesized as a mechanistic support for the modulations of perception through time. However the role of low frequency entrainment in time perception remains underexplored. Here, we asked whether the phase of entrained oscillations could be indicative of perceived relative temporal order between auditory and visual events. For this, we used a temporal recalibration paradigm in which adaptation to desynchronized audiovisual events lead to a shift of perceived temporal order towards the preceding stimulus.
Participants underwent temporal recalibration while being recorded with magnetoencephalography (MEG). Three types of adaptations were tested: synchronized audiovisual, auditory leading visual and auditory lagging visual by 200 ms. Eight adaptation blocks per condition were recorded, each followed by an assessment of participant's temporal order threshold. Stimuli were presented at an average rate of 1 Hz leading to a prominent tagging in both sensory cortices. Analyses were carried out in source space (MNE, dSPM, cortically constrained source orientations) and restricted to auditory and visual sensory cortices. Phase and power of 1 Hz oscillations in the first and last 15 trials of the adaptation blocks were compared. The preferential phase of 1 Hz oscillations significantly shifted between the beginning and the end of the adaptation period. Consistent with our hypothesis, phase shifts in each sensory cortex correlated with perceptual shifts in temporal order. Crucially, no significant power changes were observed in 1Hz. All together, our results provide a novel index of subjective simultaneity implemented as phase shift across sensory modalities. These results indicate that the relative phase of oscillations across sensory cortices can serve as an automatic "temporal marker" for the structuring of events in time.

Title: Visual attention to intermediate durations on a bisection timing task.

Authors: *A. TOSCANO ZAPIEN[1], D. VELAZQUEZ-LOPEZ[2], K. TORRES-AVILA[1], D. VELAZQUEZ MARTINEZ[1]
[1]Dept. de Psicofisiología, Facultad de Psicología., Univ. Nacional Autónoma De México, Mexico, D.F., Mexico; [2]Dept. de Matematicas, Facultad de Ciencias, Univ. Nacional Autonoma de Mexico, Mexico, D.fF., Mexico

Abstract: Time estimation is a fundamental processes underlying behavior organization. Participants were trained in a bisection task to emit differential responses to short (200 msec) or long (800 msec) visual stimulus presented at 5 different possible locations (Areas of Interest: AOI). After attaining more than 80% correct responses out of a training block of 30 trials, subjects were confronted with stimuli of intermediate durations. Cognitive models assume that pacemaker speed is related to the bisection point while attention may affect discrimination accuracy represented by Limen or Weber Fraction (WF). Subjects were instructed to fixate their gaze at a central AOI in a screen before the presentation of the stimulus to be timed; as an independent estimate of attention the time to fixation, the pupil diameter and duration of each gaze were recorded. The bisection point and Weber Fraction (derived from the behavioral responses correlated to the long stimulus) were in accordance to previous studies; longer latencies to respond were observed at intermediate durations representing the difficulty for categorizing the duration of the stimulus. Fixation times or pupil diameter of trained or intermediate durations were not related to location, color or intertrial interval. Despite that the stimulus to be timed appeared at several locations, fixations tended to be recurrent at the central AOI, suggesting that peripheral receptors (rods) in the retina may be involved in timing the stimulus. When subjects were confronted with a short stimuli, the cumulated gaze time to the long stimuli decreased, while as the duration of the stimuli increased the number of gaze visits to the central o peripheral AOIs increased. Pupil diameter increased at durations close to the bisection point or when subjects emitted ÒwrongÓ responses (response to ÒshortÓ key when confronted with a long stimulus or to the ÒlongÓ key when confronted with a short stimulus). This study raises the possibility that gaze visits may be a mediating response to time a visual stimuli.

Title: Characterization of spontaneous brain oscillations in 4-month old infants

Authors: *S. PETERS[1], G. MUSACCHIA[1], S. C. ORTIZ-MANTILLA[1], N. CHOUDHURY[2,1], A. A. BENASICH[1]

Abstract: The characterization of infant brain oscillations is an ongoing process, and is historically based on the extrapolation of frequency bands of oscillations identified in adults using electrophysiology (EEG). Spontaneous EEG oscillations, which are collected in the absence of repeated stimuli, provide a unique opportunity to examine ongoing synchronized activity in the infant brain and are strong predictors of cognitive and linguistic function. For example, higher gamma power at 16, 24 and 36 months has been related to better language abilities at 3, 4 and 5 years of age. Although cross sectional EEG spectra data exist at several infant ages, longitudinal data tracking individual development is sparse. In addition, the extent to which infant EEG corresponds to that observed in adults is not entirely clear. The present study aims to examine and characterize the spectral composition of spontaneous EEG activity in 4-month old infants as a prerequisite for tracking group and individual developmental trajectories. Participants were a subset of a larger prospective, longitudinal study. The infants were typically developing and had no family history of language impairment or abnormal perinatal circumstances. EEG signals were recorded using a 128 electrode net while the child was awake, seated in the parent's lap and silently entertained. Five minutes of spontaneous activity were recorded following 15 minutes of auditory stimulation. Using EEGLAB, data were visually inspected, artifact laden channels were removed and interpolated according to channel statistics, eyeblink artifacts were identified and removed with independent component analysis. Clean

segments of data were selected from each individual's recording for further analysis. A Morlet wavelet decomposition was applied to all of the channels in each clean segment for frequency spectrum analysis and individual averages were compiled across segments. Peaks of activity in each individual average spectrum were picked and averaged, and the topography of peak activity for each band was examined. Topographical maps showing higher frequency ranges (e.g. ~25 Hz and ~55 Hz) were stronger at central and midline regions. A leftward asymmetry was observed in a frequency band in the 4-7 Hz range and the lowest peak frequency band was most evenly distributed across channels. This is one of the few studies that have characterized oscillations describing ongoing synchronized activity in the infant brain, and provides a base from which to study developmental effects. Results of this study underscore the importance of distinguishing developmental oscillations from mature adult-like patterns.

Title: Oscillatory mechanisms for subjective temporal representations: The role of entrainment and phase resetting of ongoing neural oscillations

Authors: *R. GUEVARA, V. VAN WASSENHOVE
Neurospin, Unicog, Paris, France

Abstract: Duration perception of very fast events (at the millisecond range) is characterized by illusory distortions. Subjective duration is prone to distortions in two different ways. First, outstanding, new or surprising events tend to be perceived as longer than repetitive, or easily predicted ones. The neural correlate of this effect has been proposed to be associated with the amplitude of evoked responses, whereby the amplitude of the evoked response is suppressed by repetition and predictability. Second, and crucial for this work, events that are presented at unexpected times induce temporal distortions. The degree of this illusion might be modulated by the latency of the target event.
In this work, we propose that the neural correlates of temporal distortions are due to a change in the phase of ongoing neural oscillations. It has long been recognized that oscillatory activity is

crucial for brain information transfer and encoding. The oscillatory nature of neural rhythmical activity matches well with theoretical proposals of timing mechanisms that make use of internal clocks.
To investigate this issue we performed an MEG experiment in human subjects in which two consecutive trains of regularly spaced standardized acoustic events were repeatedly presented. To explore subjective temporal distortions, participants were asked to evaluate if the duration of a variable sound sequence was longer or shorter that the duration of a standard one. The first train was an isochronous stream and the second was variable in both tempo and phase onset (or onset latency). The use of MEG techniques was motivated by its powerful temporal resolution (as compared to fMRI) and source-reconstruction algorithms (as compared to EEG).
Psychophysical results showed that subjective duration of the non-standard acoustic train was modulated by the phase of its presentation, in accordance with previous work (McAuley & Kidd, 1998). Time frequency-analysis and phase locking analysis was performed on source-reconstructed MEG signals with a particular focus on auditory cortex. Ongoing oscillatory neural activity showed entrainment to the external (periodic) stimulation in a non-trivial way. The phase resetting of ongoing oscillations at the onset of the non-standard presentation correlated with psychophysical results, indicating that duration perception was modulated by the resetting of ongoing oscillations.
In conclusion, our results confirm the role of oscillatory activity in time perception at the millisecond scale and establish the mechanistic nature of the interaction between ongoing oscillations and external stimulation to generate perceptual illusions of temporal duration.

Title: How do cognitive mechanisms react and adjust after a disruption of the internal clock? A MEG-EEG combined study

Authors: *C. ROGER, M. BUIATTI, V. VAN WASSENHOVE
Neurospin, INSERM U992 - Cognitive Neuroimaging Unit, Gif-sur-Yvette Cedex, France

Abstract: In everyday life, the correct selection and programming of actions is a requirement of adaptation to the environment. This is made possible by cognitive control mechanisms which are engaged during perception and action. To better understand these mechanisms, researchers have investigated an EEG component, called the ERN ("Error related negativity"), which typically occurs a few milliseconds after an error is made. This component, likely generated by the anterior cingulate cortex, has been interpreted as the physiological manifestation of internal signal of error. Interestingly, the FRN ("Feedback Related Negativity") is considered the equivalent of the ERN in those situations where the error is signaled by external feedback. Both components have largely been studied in situations where errors pertain to the selection of a motor program. However, less is known about the extent to which these mechanisms are involved in situations when the required response is a judgment of when to act (at what moment) as opposed to how to act (which key to press). We hypothesized that as in the case of the selection of a motor program, cognitive control mechanisms can also make use of an internal clock to allow precise timing judgments.
To test this prediction, as well as the extent to which the internal clock is calibrated by externally generated information, we ran a study in which participants were required to estimate a duration (1.45 sec) while MEG and EEG were recorded. In each of three sessions, an initial block in which feedback on accuracy was given (too short, correct, too long) was followed by another without feedback. Feedback provided to the participants was either valid in that it was based on the actual duration to be estimated (Session 1) or not valid in that it was based on how participants responded relative to a new duration that was consistently shorter (Session 2; 1.2 sec) or longer (Session 3; 1.7 sec). Participants were not made aware of this manipulation. Preliminary ERFs results showed that the FRN first is sensitive to the information carried by the feedback, and second is reacting strongly in blocks where the feedback was invalid, i.e. in case of a mismatch between external information and internal representation of time. In a second step, we'll investigate how other brain regions get adapted to this mismatch to adapt to the new context.

Title: Enhancement of induced gamma and evoked theta oscillations underlie language-specific processing in infancy: perception of native versus non-native syllable contrasts.

Authors: *S. C. ORTIZ-MANTILLA[1], J. A. HÄMÄLÄINEN[2], A. A. BENASICH[1]
[1]Rutgers The State Univ. of New Jersey, NEWARK, NJ; [2]Univ. of Jyväskylä, Jyväskylä, Finland

Abstract: Brain electrical signals recorded at the scalp reflect variations on spontaneous neuronal activity as well as time-locked activity after stimulus presentation (event-related potentials, ERPs). During sensory stimulation, event-related oscillations (EROs) are enhanced and generate evoked (phase-locked) and induced (nonphase-locked) rhythmic activity. In adults, stimulus-induced modulation of cortical rhythms has been found in the theta (3-7 Hz) and gamma (30-80 Hz) bands during speech perception. Oscillatory activity in the slow theta range is hypothesized to resolve information at the syllable level while fast gamma activity may resolve acoustic information at the segment level. However, very little is known about the spectral composition of infant ERPs during perception of syllables in the infant's native or non-native language. A group of normally developing 6-month-olds, born in English monolingual families, were presented with a two-deviant passive oddball paradigm using 3 stimuli: 80% of the time a standard consonant-vowel syllable (phonetically relevant in both English and Spanish), 10% a native deviant (phonetically relevant in English) and 10% a non-native deviant (phonetically relevant in Spanish). Dense-array EEG/ERPs were collected using a 62-channel EGI net and mapped into age-appropriate brain templates. Source modeling placed dipoles in auditory cortices and frontally, at anterior cingulate cortex. Temporal-spectral analyses of EROs were conducted in source space using a 2-80 Hz frequency band range, from -300 to 930 ms, with 1 Hz wide frequency bins and time resolution of 50 ms. Dynamic changes in frequency band amplitude, as a function of time relative to stimulus presentation, were evaluated by temporal spectral evolution (TSE) measures. Inter-trial phase locking (ITPL) values measured how consistently the phase at different frequency bands locked to cross-trial stimulation. Induced activity was calculated by subtracting the evoked activity from the TSE signal. Permutation testing in combination with data clustering analysis showed significant increases in theta band ITPL for native deviant as compared to standard processing in left auditory cortex. Enhancement of frontal oscillatory activity in the gamma band was seen during processing of the native deviant but not for standard or non-native deviant. Our results suggest that in a period critical for setting-up language, at least part of the infant auditory change detection response to native signals can be attributed to alignment of brain oscillations in the theta band, particularly in left auditory cortex, and to an increase in induced gamma activity in frontal areas.

Title: Testing the predictions of a Bayesian model for tactile spatiotemporal perception

Authors: *J. TONG, D. GOLDREICH
Psychology, Dept. of Psychology, McMaster Univ., Hamilton, ON, Canada

Abstract: When brief stimuli contact the skin in rapid succession at two locations, tactile perception remarkably underestimates the intervening distance, and overestimates the elapsed time, between events. These two phenomena - perceptual length contraction and time dilation - become progressively more pronounced as the actual distance between stimulus sites, divided by the elapsed time between stimuli, increases. Goldreich (2007) proposed that these tactile spatiotemporal illusions result from a process of Bayesian inference in which the brain interprets noisy sensorineural inputs in light of a prior expectation for low-speed movement along the skin. Conceptually, this tactile perceptual model is similar to a low-speed-prior visual perceptual model (Weiss et al., 2002). In its simplest form, the model has a single free parameter reflecting the precision of the low-speed prior relative to the skin's spatial acuity. Here we report preliminary results from ongoing psychophysical experiments designed to test the model's predictions. We separately measured subjects' tactile spatial and temporal acuity, using stimuli that do not evoke illusory percepts. We then characterized subjects' illusory perception of spatiotemporal sequences of varying speeds. Preliminary results suggest that the illusory percepts experienced by individual subjects conform rather well to those predicted by the model

Title: The brain is sensitive to subjective rhythmization: Evidence on the role of alpha oscillations

Authors: *C. OBERMEIER[1], M. VON KOPPENFELS[2], W. MENNINGHAUS[3], S. A. KOTZ[1]
[1]Max Planck Inst. for Human Cognitive and Brain Sci., Leipzig, Germany; [2]Inst. of Comparative Literature, Ludwig Maximilians Univ., Munich, Germany; [3]Inst. of Comparative Literature/Cluster 'Languages of Emotion', Free Univ. of Berlin, Berlin, Germany

Abstract: When listening to identical tones in an isochronous sequence (equitone sequence), participants often perceive some tones as more salient than others (e.g. Brochard et al., 2003). This phenomenon is termed subjective accenting and has been related to auditory perceptual organization. According to the dynamic attending theory (e.g. Large & Jones, 1999), listeners establish rhythmic expectancies from the first few events of a sequence. This information is then used to direct attention to specific tones and to temporally predict future events. However, little is known about the underlying neural mechanisms. Here, we used a combined ERP/time-frequency(TF) approach to clarify a) how listeners subjectively establish rhythmic regularities in equitone sequences and b) how they use this information to predict upcoming events. In particular, alpha oscillations (8-12 Hz), often related to attention and memory processes (e.g. Klimesch et al., 2010), may play an important role in the formation of such rhythmic regularities and expectancies.
For this purpose, we presented participants with 96 sequences of 13 to 16 identical tones that either contained one or two deviants at odd- or even-numbered positions. Standard tones had a frequency of 440 Hz, a duration of 50 ms, and an intensity level of 70 dB. Deviant tones were attenuated by 4 dB. The interval between tones was 600 ms. Participants counted the number of loudness changes encountered in a sequence. We measured ERPs to deviant tones and performed TF analyses on the deviant and pre-deviant tones.
The ERP analysis revealed an increased P50 as well as P300 for deviant tones in odd positions in contrast to deviants in even positions extending previous ERP findings on equitone sequence processing (e.g. Brochard et al., 2003; Schmidt-Kassow et al., 2011). The TF analysis showed reduced alpha power for deviants in odd positions compared to deviants in even positions. In contrast, alpha power was enhanced for pre-deviant tones in odd positions compared to pre-deviant tones in even positions. Furthermore, alpha power increased up to tone 4 of a sequence, followed by a decrease in alpha power up to the first deviant.

Thus, the present study is the first to show that differences in alpha oscillations between odd- and even numbered tones of a sequence reflect the establishment of subjective rhythmic regularities and expectancies. In addition, the combined ERP and TF data on the deviant tones show that these subjective rhythmic expectancies are used to predict upcoming events in a sequence.

Title: Effects of chronic video game use on timing: Differences between sub-second and multi-second intervals

Authors: *M. B. REYES[1], T. S. RIVERO[2], C. PRISCILA[2], O. F. A. BUENO[2]
[1]CMCC, Univ. Federal Do ABC, Santo André, Brazil; [2]Psicobiologia, Universidadade Federal de São Paulo, São Paulo, Brazil

Abstract: Video game is an everyday part of normal childhood and adolescence in today's society. It is therefore worth investigating the potential effects of its chronic use on cognition. Even though video game players frequently report losing track of time while playing, only a few studies have addressed whether there are long lasting effects of such activities on time perception. In order to investigate this question, we compared the performance of a group of chronic video game players, who reported playing more than 40 hours per week, with occasional players, who played less than 5 hours per week in regularly used time perception tasks. Multi-seconds time perception was assessed by time estimation (10, 30 and 60 seconds) and a time production (5 and 45 seconds) tasks. To investigate the time perception in the sub-second range, we utilized a time discrimination task, in which subjects compared intervals varying from 100 milliseconds up to 1000 milliseconds with a reference duration (500 ms), and a bisection interval task, with stimuli varying from 200 to 800 milliseconds. Results show that video game players

had significant superior performance on sub-second tasks. These results point out for a long lasting effect of video game chronic use on time perception.

Title: Temporal limit of face perception in children and adults

Authors: *F. FARZIN, A. NORCIA
Dept. of Psychology, Stanford Univ., Stanford, CA

Abstract: Visual processing has a limited temporal resolution, which varies according to complexity of information being processed and cortical area. Early stages can process basic luminance information at faster rates than later stages that are required to form a global object representation. The purpose of the current study was to determine the temporal processing capacity for face perception in children and in adults, in order to begin characterizing the functional development of temporal visual processing.
To measure the temporal resolution of face perception we recorded high-density steady-state visual evoked potentials (ssVEPs) in response to a phase-scrambled and an intact face image alternating at a fixed temporal frequency, ranging from a rate of 2-9 Hz. The ssVEP technique is ideal for measuring temporal processing because it directly assesses the time-locked cortical processing of visual information at different rates, from which we can estimate a temporal limit. By design, face-specific responses are elicited only at the odd harmonics of the alternation rate. Responses at the even harmonics are elicited after each image presentation and are thus non-specific to the face. Participants included 16 children (ages 8-12 years) and 11 adults (ages 18-35 years).
Individuals' response amplitude at the first (1F) and the second (2F) harmonic was calculated for electrodes over left, right, and medial occipital areas for each temporal frequency condition. All participants showed a bilateral face-specific response over occipitotemporal areas, and the magnitude of the response was dependent on temporal frequency. Adult 1F responses were maximal around 4 Hz and were not present at 9 Hz, while childrens' 1F responses were maximal at the lowest frequencies and were not present above 4 Hz. Both age groups showed a 2F

response restricted to medial occipital areas, which was present at all temporal frequencies. These results are consistent with the theory that visual information processed at a higher stage, in this case the natural image of a face, is limited to low temporal rates, and demonstrate that temporal resolution increases during development.

Title: How does the brain combine temporal information from multiple sources to judge duration?

Authors: *M. CAI, D. M. EAGLEMAN
Neurosci., Baylor Col. of Med., Houston, TX

Abstract: Recent studies have demonstrated that the perception of duration can be changed by particular properties of a sensory stimulus. For example, a visual stimulus with higher temporal frequency is perceived to be longer than one with lower temporal frequency of the same physical duration (Kanai et al., 2006). Together with other findings, this supports the idea that the brain can use stimulus properties to estimate duration, contrary to the traditional view of time perception based on an internal clock that is independent of environment. Johnston et al. (2006) have further shown that duration perception can be distorted in a local retinotopic area. Together, these findings lead to an important question: how does the brain form a single duration representation when different visual stimuli provide conflicting information about duration? Specifically, a high temporal frequency stimulus results in a longer perceived duration than a low temporal frequency stimulus when they are presented separately. How does the brain perceive their duration if they are presented simultaneously? To answer this specific question, we conducted experiments in which participants judged the durations of several types of visual stimuli: a static Gabor pattern, a single Gabor pattern drifting at high temporal frequency (6Hz), a single Gabor pattern drifting at low temporal frequency (1Hz), or two simultaneous Gabor patterns, one drifting at low (1Hz) and one at high (6Hz) temporal frequency. Our results confirmed previous finding that high temporal frequency stimuli are perceived to be longer than low temporal frequency stimulus, and both are perceived to be longer than a static stimulus.

When comparing each type of drifting stimulus against a static stimulus, the perceived duration is significantly longer for a single high temporal frequency stimulus than for two stimuli of high and low temporal frequencies presented simultaneously. However, when directly comparing the duration of one stimulus of high temporal frequency against two simultaneously presented stimuli of high and low temporal frequencies, they are judged as equally long. Taken together, we argue that the brain may integrate conflicting information of duration from multiple sensory stimuli in a Bayesian way similar to cue integration, but only when comparing stimuli within the same temporal frequency channel is impossible. When comparison within channel is possible, separate representations of duration from each channel can be kept for comparison to reduce bias.

Title: 'Priming' the brain to generate rapid upper-limb reactions

Authors: *B. LAKHANI[1,2], V. MIYASIKE-DASILVA[3], A. H. VETTE[3], W. E. MCILROY[1,2,3]
[1]Univ. of Toronto, Toronto, ON, Canada; [2]Toronto Rehabil. Inst., Toronto, ON, Canada; [3]Kinesiology, Univ. of Waterloo, Waterloo, ON, Canada

Abstract: Background: In situations where urgent responses are essential, individuals with neurological impairments tend to be slow to react. Given the lack of insight into the underlying causes, the present work aims to advance the fundamental understanding of mechanisms that determine rapid reactions. Our previous research demonstrated that balance recovery responses generate reaction times that are significantly faster than cued volitional movements. As studies have been unable to reproduce these rapid reaction times in the absence of a balance disturbance, the afferent input evoked by a whole-body perturbation may be an important modulator of reaction time. The primary objective of the current study is to temporally pair auditory stimuli with whole-body perturbations to determine if conditioning can 'prime' the central nervous system (CNS) to respond faster to an auditory stimulus alone.
Methods: Healthy young adults (n=19) were seated in a custom chair, which tilted backwards upon the release of an electromagnet, and were instructed to reach-to-grasp a handle located in front of their dominant arm as fast as possible following an auditory cue. Three conditions were

completed in the following order: 1) *Baseline* - Auditory cue alone (5 trials); 2) *Paired* - Auditory cue, followed by a chair tilt 110 ms later (20 trials); and 3) *Auditory (post-pairing)* - Auditory cue alone (1 trial). Participants were not informed that the final trial, following the series of paired stimuli, would be *Auditory* alone. Reaction time was measured using electromyography (anterior deltoid onset), and autonomic nervous system activity was monitored via the electrodermal response (EDR).
Results: In the *Auditory (post-pairing)* condition compared to *baseline*, the reaction time was significantly faster (Δ = 40 ms; $p<0.0001$) and the amplitude of the EDR was significantly greater ($p=0.0159$). At the same time, the amplitude of contraction and overall time to handle contact were not significantly different between the *Auditory – post-pairing* and *Baseline* conditions ($p=0.1078$ and $p=0.5436$, respectively).
Conclusions: This study demonstrates that the CNS can be primed to generate rapid reactions in the absence of whole-body instability. The ability to reduce reaction time and boost the phasic EDR in response to an auditory stimulus indicates that the volume of somatosensory afferent information following a whole body disturbance is not the critical determinant of rapid reactions, emphasizing the role of stimulus context on reaction time. Ongoing work is focused on characterizing the mechanisms responsible for augmentation of processing speed along the sensorimotor pathway.

Title: Encoding sensory and temporal components of expected outcomes

Authors: *N. NADLER[1,2], A. DELAMATER[3]
[1]CUNY, New York, NY; [2]Grad. Center, CUNY, New York, NY; [3]Brooklyn College, CUNY, New York, NY

Abstract: In computer based reaction time (RT) tasks, exploring whether the sensory and temporal attributes of the unconditioned stimulus are separable, human participants learned the relationships between distinct cues and associated targets to which they were to respond or not. The tasks involved the presentation of specific cue-target relationships and subjects were asked

to respond with a single button press. Two cues (distinct geometric shapes), were initially trained to predict different colored boxes. Additional trials occurred in which both cues were associated with a third target stimulus to which they were not to respond. Each trial began with a 1500ms fixation cross, followed by the presentation of a cue for 300ms, and then, after a 500ms gap, the target stimulus was presented for 1000ms or until the subject responded. The interstimulus interval was 800ms in training and varied in test. Reaction time data revealed that overall people responded slower when the targets were presented earlier than usual during the test phase, F(2, 58) = 9.262, p < .001, but, more importantly, that they also responded faster to validly cued targets (i.e., A-T1, B-T2) than invalidly cued targets (i.e., A-T2, B-T1), F(1, 29) = 4.321, p < .05. Importantly, this validity effect did not interact with ISI. The task results support that these attributes are encoded separately as participants responded more slowly to invalidly cued than validly cued targets, and RT was affected by varying the temporal presentation between the cues and targets, however, there was no interaction between these sensory and temporal components. These data indicate that people learn to associate cues with both the identity and temporal qualities of the target stimulus.

Title: On the relationship between neural coding and the perception of the present moment.

Authors: *L. S. SMITH
Univ. of Stirling, Stirling, United Kingdom

Abstract: Temporal processing takes place at many scales, from tens of microseconds to years. From a sensory perspective, although one might consider olfaction to be the momentary concentration of molecules, visual perception normally uses visual context, and sound perception is of changing sound pressures. The auditory sense is most sensitive to time: we can distinguish two clicks that are 10ms apart. Our perception of the present moment differs from both the physicist’s perspective, where the moment is infinitesimally short, and the minimum detectable time interval. As William James noted in1890, “the sensible present has duration”, and that duration, is not fixed, but is of the order of a few seconds, much longer than 10ms. What gives it that duration? At a much lower level, from a behavior perspective, even simple single celled

organisms do not appear to experience time as physicists describe it, but have a number of timescales. For them, there is again always context, implemented by the internal content of the cell, in turn modulating the pores (channels) of the cell, and the sensors and actuators on the cell surface, so that the cell's behavior depends not just on the instantaneous environment, but on the environment over some extended period. For animals with neural systems, whose behavior is expressed by the whole animal, and not by single cells, context is implemented primarily neurally. Neural coding itself takes time: a single spike is the shortest possible code, but both rate coding and codes formed from combinations of spikes (except absolutely co-incident spikes) all take time to form. Cognitively speaking, we live "in the present moment", but what does this mean? Is it a issue purely of neural coding, or are there signaling cycles involved? The duration of the "sensible present" suggests something more than simple rate coding, or single informational patterns of spikes: yet the rapidity of the effect of (particularly unexpected) sensory stimuli suggests that the "present moment's" percept can be altered by a very small number of spikes. The duration of the "sensible present" is affected by what the person is doing. For example, in meditative states, where attention is not given to stimuli, it can be short, and in concentrated states, like playing a piece of music on an instrument, or scoring a goal in football, it can be extended. This suggests that a number of collaborating neural effects cause the build-up of the "sensible present". There is clearly a subjective element in the concept, making it difficult to measure. We model the relationship between the physical present, the "present" for unicellular animals, and the "sensible present" for animals with neural systems.

Title: Temporal prediction errors modulate cingulate-insular coupling

Authors: *R. LIMONGI[1], S. C. SUTHERLAND[2], J. ZHU[2], M. E. YOUNG[2], R. HABIB[2]

Abstract: Prediction error (i.e., the difference between the expected and actual event outcome) mediates adaptive behavior. Activity in the anterior midcingulate cortex (aMCC) and in the anterior insula (aINS) is associated with the commission of prediction errors under uncertainty. We propose a model of effective connectivity (neuronal coupling) between the aMCC and the aINS in which the task-context and the temporal prediction errors drives and modulate intrinsic and extrinsic connections respectively. With fMRI, 15 participants were scanned while performing a temporal prediction task. They observed visual animations and predicted when a stationary ball launched after being contacted by a moving ball. Three spatial gaps and three temporal delays between the balls introduced uncertainties in the launching time thus inducing prediction errors. The fMRI analysis provides evidence that the aMCC-aINS system not only responds when humans predict *whether* an event occurs but also *when* it is to occur. The dynamic causal model demonstrates that uncertainty-related tasks drive activity in the aINS and that aMCC-aINS projections are modulated as a linear function of the prediction errors. Our results inform current questions regarding the predictive functions of the insular cortex, the cingulate gyrus, and the conjoint aINS-aMCC system. Our model gives rise to the question of whether signals associated with temporal prediction errors originate in the ventral striatum or in the ventral tegmental area.

Title: Sleep deprivation slows visual processing in higher visual cortex

Authors: *D. KONG[1,2], C. L. ASPLUND[1], M. W. L. CHEE[1]
[1]Duke-Nus Grad. Med. Sch., Singapore, Singapore; [2]NUS Grad. Sch. for Integrative Sci. and Engin., Natl. Univ. of Singapore, Singapore, Singapore

Abstract: Sleep deprivation (SD) can impair attention and slow processing. An important underlying mechanism that has not been well characterized is its effect on temporal processing capacity, the rate at which visual information can be processed. Here we adapted McKeeff's (2007) rapid serial visual presentation (RSVP) paradigm to investigate if SD reduces temporal processing capacity.
Healthy young adults (n=13) underwent fMRI after a normal night of sleep during rested wakefulness (RW) and following 24h SD in counterbalanced order. Participants searched for targets in RSVP sequences of houses presented at different rates (4, 6, 8.5, 12, 15 and 20 items/s).
fMRI was used to measure visual cortex activation associated with the RSVP task. Early visual cortex ROI were determined using retinotopic mapping. The ROI used PPA analysis was based on an independent PPA localizer task. Temporal processing capacity was inferred from the presentation rate that maximized PPA activation. We predicted that SD would reduce the rate at which the maximum fMRI response was elicited.
Participants responded more quickly and accurately to targets during RW than following SD and when presentation rates were slow. fMRI responses in PPA mirrored these behavioral effects. Activity in PPA during RW increased from 4 to 6 items/s, and then dropped for all faster rates. Interestingly, during SD, PPA activation showed a leftward shift in peak activity toward 4 items/s, suggesting a reduction in temporal processing capacity. Contrastingly, activity in early visual cortex rose till 8.5 items/s and plateaued till 20 items/s. This activity showed a non-significant trend towards lower activation with the same temporal profile during SD.
These findings suggest that SD reduces the rate of object processing in higher order but not early visual cortex and may have implications when speeded recognition of objects is critical to performance.

Title: Visual and auditory timing interventions targeting magnocellular functioning in children significantly improve reading skills.

Authors: *T. A. LAWTON[1], S. ROSENBERG[1], K. LAWTON[1], J. CONWAY[2], S. D. EDLAND[3]
[1]Computer Sci. and Engin., Univ. of California San Diego, La Jolla, CA; [2]Cognitive Sci., [3]Neurosciences, Family Preventive Medicine, Div. Biostatics, UCSD, La Jolla, CA

Abstract: There is no greater educational problem facing our schools than students who have trouble reading. We hypothesize that a temporal processing deficit in both the auditory and visual pathways may be a key factor limiting reading performance. To investigate the efficacy of reading interventions designed to improve temporal processing speed, we compared two timing interventions, FastForWord (FFW) targeting the temporal dynamics of the auditory pathway, and PATHtoReading (PATH) targeting the temporal dynamics of the visual pathway. Both of these interventions, designed to improve temporal processing in the brain by increasing the sensitivity of magnocellular neurons in the motion or dorsal pathway, have been shown to be efficacious in randomized trials. This study examined whether FFW and PATH, which activate separate sensory modalities, can be combined into an intervention that results in an even greater benefit. We ran a randomized trial on dyslexic second graders in 7 public elementary schools in San Diego that includes a wide ethnic distribution of predominantly low socio-economic status students, comparing business-as-usual (control group), FFW, PATH, FFW and PATH combined, Orientation Discrimination (OD), and a group that did PATH followed by OD. The OD intervention was designed to train the pattern-sensitive ventral pathway composed of predominantly parvocellular neurons. FFW was done for 30 minutes, 5 days a week for 20 weeks. PATH and OD were done for 10-20 minutes, depending on child's ease of attending, 3 days a week for 20 weeks, doing silent reading in the remaining 30 minutes. Standardized tests of reading fluency and attention were the measures used to evaluate improvements in reading skills. ANCOVAs controlling for age, sex, ethnicity, English as second language status, and school enrolled were used to compare treatment response across groups. We found that PATH improved reading grade level significantly compared to business-as-usual, especially when combined with FFW, suggesting that visual and auditory temporal processing are fundamental for learning to read, contrary to claims that reading is only phonologically-based. Different models to explain these results will be discussed.

Title: Evaluation of cognitive impairment in alcohol consumers using temporal Information

Authors: *H. SANCHEZ-CASTILLO[1], D. RAMOS-MASTACHE[2], D. B. PAZ-TREJO[2]
[1]Psicofisiología Fac Psicologia, UNAM (national Univ. of Mexico), Mexico, Mexico;
[2]Psicobiologia y Neurociencias. Facultad de Psicologia, Univ. Nacional Autonoma de Mexico, Mexico City, Mexico

Abstract: There is evidence that chronic consume of alcohol could cause impairment in concentration, executive functions and decision-making process. Several studies have shown that alcohol can cause cognitive deterioration that could decrease addict's performance in information processing tasks. Because of the previous statement it has been proposed that the models of timing can be an excellent tool to evaluate attention, concentration and memory on these subjects because they involved a series of cognitive areas, that is why the aim of the study was to evaluate this cognitive abilities in patients with chronic alcoholism using temporal estimation tasks to determine if exist impairment in processes such as memory and decision making. To evaluate these cognitive functions we took alcoholic patients from a "Celia Meneses Rehabilitation Center". We propose to made three bisection tasks with different interval times to observe if there may be differences in the in the participants information processing according to the speed of the stimuli, we hypothesized that the alcoholics will discriminate worse the short stimuli and better the long stimuli because they will have more time to process information. The first bisection task has an interval time between 100 and 400ms, the seconds one is between 200- and 800ms and the third one is between 400- 1600ms. The results showed that the chronic alcohol consumers present more difficulties in discriminating short stimuli than long stimuli, this was observed in an increase of the limen and the Weber fraction. This is corroborated by previous studies that have shown that the ability to discriminate between different interval times

correlates directly with the stimuli duration. This previous statements led us to think that there may be an impulsivity conduct related to the deterioration observed in alcoholics.

Title: Saccadic latency as a window on temporal processing

Authors: *M. MISSAL[1], L. QUENON[1], J. MODENA[1], R. CARPENTER[2]
[1]Lab. de Neurophysiologie, Inst. of Neurosciences, IONS - COSY, Brussels, Belgium; [2]Dept. of Physiology, Develop. and Neurosci., Cambridge Univ., Cambridge, United Kingdom

Abstract: Anticipatory eye movements are often evoked by temporal expectation of an upcoming event. Temporal expectation builds up on the basis of an implicit estimate of the changing probability of occurrence of an event (hazard rate). Implicit timing relies on a sense of the passage of time that is not voluntarily controlled. However, anticipation about when an event could occur can also be based on an explicit estimate of time on the basis of information stored in memory. Explicit timing requires attention.
Explicit and implicit timing processes are thought to be under the control of different neural structures. We tested this hypothesis by the analysis of the latency of saccades in a paradigm where movement latency was used as a biomarker of temporal processing. Indeed, decisions based on different timing processes should lead to different saccadic latency distributions. Human subjects were required to make a saccadic eye movement towards a visual target appearing on a screen after a delay period that could take one of four different values randomly (400 ms, 900 ms, 1400 ms and 1900 ms). In the implicit timing experiment, no temporal information was provided about the duration of the delay. In the explicit timing experiment, subjects were informed of the duration of the delay period by the previous display of a visual cue at the center of the screen. The duration of the visual cue was equal to the duration of the

following delay period.
We found that during the implicit timing experience the average latency of saccades with respect to target onset decreased with increasing delay duration. Moreover, the fraction of anticipatory saccades also increased with delay duration. This effect was probably caused by a perception of the changing probability of target appearance as time elapsed during the delay. During the explicit timing experiments even more anticipatory saccades were observed. Importantly, the shape of saccadic latency distributions was different in the implicit and explicit timing experiments. These results support the hypothesis of the existence and relative independence of two different neural systems for timing.

Title: Capturing task-evoked functional brain connectivity using eeg

Authors: N. SHAHNI KARAMZADEH[1], A. MEDVEDEV[2], A. BAKHTIAR[1], *A. GANDJBAKHCHE[1], L. NAJAFIZADEH[1,3]
[1]Natl. Inst. of Child Hlth. and Human Develop., NIH, Bethesda, MD; [2]2)Center for Functional and Mol. Imaging, Georgetown Univ., Washington, DC; [3]3)Center for Neurosci. and Regenerative Medicine, Henry M. Jackson Fndn., Bethesda, MD

Abstract: Functional brain connectivity refers to the statistical dependencies of the remote regions of the brain. Existing technologies used for monitoring brain activity have allowed researchers to explore functional connectivity from different aspects. Electroencephalography (EEG) system is one example that captures brain's neuronal activity by its electrodes distributed over the scalp.
A primary step toward understanding the brain's functional connectivity is employing an appropriate metric for investigating EEG data's proximity. These metrics could be built in the frequency domain or in the time domain, such as Euclidean distance, correlation, Dynamic Time Warping (DTW), and probabilistic model-based approaches like Hidden Markov Model.
In this paper, we will investigate brain's functional connectivity in the time domain. We propose an automatic and unsupervised paradigm for understating the brain's functional connectivity by employing cluster analysis which is mostly used in the machine learning field.

One auditory and one modified visual oddball task were tested for 5 subjects. In the auditory task, auditory stimuli were presented for 50 ms in. The stimuli were 1000 Hz (non-target) and 2000 Hz (target) in frequency, and 80 dBSL in intensity. Target stimuli were presented with the probability of 15%.
For the visual task, sequences of three stimuli were presented. Duration for broadcasting the stimulus was 50 ms. The target stimuli appeared with the probability of 15%, whereas the two non-target stimuli appeared frequently and infrequently with the probability of 58% and 25%, respectively. Overall, 50 target and 250 non-target stimuli were presented.
A proximity matrix was constructed by employing the DTW metric. On each pair of EEG signals, the DTW algorithm uses a dynamic programming to generate the most representative distance measure of their overall difference.
ERP signals from the two tasks were analyzed and the DTW-based clustering technique was applied for both cases. Clustering on the EEG data resulted in multiple clusters for each subject. The common cluster among all the five subjects was selected as the region that had shown similar behavior. Our proposed technique was able to capture very detailed similarities where a method such as correlation would fail.
A future direction of this work may be extending the proposed technique to be applied on at temporal-subset of the EEG's signal during the experiment. This approach has the advantage of revealing more number of potential functionally connected regions in smaller temporal-during an experiment.

Abstract: It is increasing being acknowledged that cortical networks exhibit replay of previously experienced sensory information in the absence of stimulation. Neuronal replay has been proposed as a possible mechanism for memory consolidation in cortical networks. In addition, neuronal replay has been associated with efficient encoding of information and improved perceptual performance. Whether and how replay occurs in human cortical areas is unclear. We have recorded from multiple cortical areas using electrocorticography (ECoG) in human patients undergoing treatment for epilepsy. We measured neuronal activity in four patients using ECoG and assessed replay across multiple frequency bands. The experiment consisted of multiple trials in which human observers were exposed to either short cartoon movies or blank screens (25 pre-stimulus trials, 50 interleaved movie and blank trials and 25 post-stimulus trials). During each trial (5.5 s) subjects were required to perform a letter identification task in the center of a computer screen (subjects maintained a 95% correct response rate across trials). To evaluate cortical replay we computed the similarity between neuronal responses in the movie, blank, and pre-stimulus conditions, by employing spectral analysis. Specifically, we computed the correlation distance between the binned Hilbert amplitude (BHA) of neuronal responses in each stimulus condition. If the degree of similarity was significantly higher in the movie/blank correlations than the pre-stimulus/movie correlations, the electrode was considered to exhibit cortical replay. We observed that, irrespective of cortical location, the highest percentage of replay electrodes (around 60%) was found in γ1 (32-64 Hz) and γ2 (64-128 Hz) bands. Using the correlation distance, we found the highest percentage of replay electrodes (around 44%) in γ1 and γ2 bands in frontal (N = 35 electrodes) and temporal lobes (N = 29 electrodes). In addition, replay electrodes exhibited significantly lower spectral differences between movie/blank than between pre-stimulus/movie. Finally, we measured the coherence between a pair of electrodes within and between cortical areas for each stimulus condition. We observed that the difference in coherence for the movie/blank condition was smaller than the difference for the pre-stimulus/movie condition irrespective of electrode location, specifically in the theta and gamma frequency bands. Our results indicate a surprising degree of plasticity in human cortical networks in the absence of visual stimulation that may constitute the neural basis of learning by stimulus exposure in the absence of attention.

Title: Can one keep to rhythm accurately? Depends on the underlying white matter structure.

Authors: *S. SHANKER, N. DAVIS, R. M. BRACEWELL, A. DAVIDSON, P. MULLINS
Sch. of Psychology, Bangor Univ., Gwynedd, United Kingdom

Abstract: A wide network of brain areas is involved in the control of timing. Control of force, and co-regulation of timing and force, have been primarily associated with basal ganglia structures; while general timing functions have been associated with cerebellar structures. These key structures in the brain are connected through white matter tracts
This study looks at the correlation of behavioral performance on timing tasks with fractional anisotropy (FA) of specific tracts derived from diffusion tensor imaging (DTI). In two behavioural experiments, we asked participants (N=11; mean age = 27.5 years) to either tap (a ballistic movement of the index finger) or pulse (the index finger continuously touches the surface) the finger in a specific rhythm. At onset of the block participants received aural and visual feedback to assist timing (synchronization phase). Feedback was then withdrawn and participants asked to continue to respond (continuation phase). Across the experiments we varied timing constraints (isochronous or rhythmic) and force constraints (constant peak force or varying force). Using the Wing-Kristofferson model we calculated the motor and clock variance of the inter-response intervals (IRIs). We also looked at the mean temporal drift in IRI for each condition. FA measures from the internal capsule (i.e. frontopontine fibers, corticospinal tract), the external capsule, and the superior cerebellar peduncle (SCP) were calculated from DTI obtained at 3T. We interpret higher FA values in a particular tract as being suggestive of greater myelination. Preliminary results show a positive correlation ($p < .01$, $r = .77$) between clock variance and FA of the internal capsule and SCP. A tract connecting the hand area in the primary motor cortex (M1) to the cerebellum and to the brainstem via the thalamus was identified, and had connections with the frontal lobe. Our results indicate that FA values for these tracts (referred to as timing pathways) can predict how well individuals can keep to time or rhythm. In future such analyses could be extended to study timing networks in patients with Parkinson's disease and cerebellar stroke.

Title: Cortico-limbic interactions in social information processing

Authors: *K. SCHNELL[1], M. M. SCHMITGEN[2], S. BLUSCHKE[3], H. WALTER[4]
[1]Klinik für Allgemeine Psychiatrie Universitätsklinik Heidelberg, [2]Univ. Hosp. Heidelberg / Dept. of Gen. Psychiatry, Heidelberg, Germany; [3]Psychiatry and Psychotherapy, Univ. Hosp. Bonn, Bonn, Germany; [4]Dept. of Psychiatry and Psychotherapy, Charité Universitätsmedizin Berlin, Campus Mitte/ Div. of Mind and Brain Res., Berlin, Germany

Abstract: Research on social-cognitive functions of the human brain provides both, basic insights in the brains functional anatomy as well as promising endophenotypes of mental disorders (Walter et al. 2011). Social cognitions potentially involve cognition about social context and affective experience. It is of great interest, if these functions are linked to separate or overlapping functional systems of the human brain.
In two fMRI (3T) experiments we explored, if the i.) affective vs. non affective focus of cognition and ii.) the presence vs. absence of affective sensory stimuli elicits disparate or simultaneous activations of limbic structures involved in emotion processing (amygdala, hippocampus (HC)) and cortical networks associated with theory of mind (ToM: Minferring on mental content of others') generation - (dorsomedial PFC, superior temporal sulcus (STS) and temporoperietal junction).
First (Schnell et al. 2011) we explored the functional effects of affective/nonaffective content and cognitive perspective (1st person/3rd person) in social cognition in 28 participants. To control effects of stimulus features, 32 false-belief cartoon stories (3 pictures each) were randomly assigned to the 4 conditions. Within the 3rd person perspective, affective focus of cognition (vs. non affective focus) was linked to coactivation of the anterior ToM network (dmPFC, STS) and limbic system (left amygdale,HC). In general, anterior ToM-network activation was driven by affective content. In contrast, activation of the temporoparietal junction was associated with adaption of the 3rd person perspective.
In the second, yet unpublished, study 22 healthy participants constantly judged affective states of the story protagonist (3rd person affective perspective), while 10 cartoon stories contained facial expressions and 10 did not. The presence of affective stimuli elicited activation of both amygdalae and visual cortex, additionally modulated by the affective stimulus valence. Analysis of psychophysiological interaction revealed that the presence/absence of affective sensory signals modulated functional connectivity between right amydala and orbitofrontal cortex (OFC). Analysis of a structural equation model revealed direct interaction of amygdala and mPFC, which was, in turn, connected to OFC.
Our results indicate that co-activation of the cortical ToM-network and the limbic system depends on the affective focus of social cognitions. Within this cognitive focus, direct affective

signals resulted in additional amydala activation and modulated functional amydala-OFC connectivity, most likely relayed by the medial prefrontal cortex.

Title: Valence modulates dorsomedial prefrontal cortex engagement during impression formation in healthy aging

Authors: *B. S. CASSIDY, E. D. LESHIKAR, A. H. GUTCHESS
Dept. of Psychology, Brandeis Univ., Waltham, MA

Abstract: Previous neuroimaging studies have demonstrated reliable engagement of the dorsomedial prefrontal cortex (dmPFC) during impression formation in both young and older adults. It is an open question, however, whether dmPFC is differentially recruited depending on the content (i.e., valence) of incoming social information. Extensive evidence suggests the existence of a negativity bias in young adults in many domains, including impression formation, memory, and moral judgment. Older adults, by contrast, show a positivity bias and tend to focus on more positive and emotionally meaningful material. This negativity bias reversal is apparent in the neural underpinnings of emotion processing, such that while young adults activate ventromedial prefrontal cortex (vmPFC) more when viewing negative over positive images, the reverse is evident in older adults. In this fMRI experiment, we investigated whether these reversals extended to impression formation. We explored dmPFC engagement in young and older adults when individuals spontaneously formed positive and negative impressions after learning about and reflecting on others' behaviors. Nineteen young and eighteen older adults viewed faces paired with behaviors varying in positive, negative, and neutral valence. Participants were instructed to focus on how each face-behavior pair made them feel. Consistent with prior evidence of a negativity bias in impression formation, young adults exhibited increased activation of dmPFC when focusing on how they felt about the negative relative to the positive face-behavior pairs. In contrast, older adults displayed increased recruitment of dmPFC

when focusing on how they felt about the positive relative to the negative face-behavior pairs. These findings lend credence to the idea that while young adults may place more weight on evaluating negative over positive person information when spontaneously forming impressions, older adults emphasize positive incoming person information, perhaps as a result of changing socioemotional goals. These data also show that age-related negativity bias reversals, seen in vmPFC activity during emotion processing, are also present in dmPFC engagement when forming impressions. Thus, while dmPFC function during impression formation may be spared with age, its recruitment may be influenced by the valence of incoming social material.

Title: Spatial and temporal distance decreases empathic responses to others' suffering

Authors: *D. I. TAMIR, E. M. TEMPLETON, M. D. FERREOL, J. P. MITCHELL
Harvard Univ., Cambridge, MA

Abstract: The human capacity for empathy allows an individual share in the experiences of others. Empathy for negative experiences, such as pain or suffering, allows one to respond to others with help and kindness, responses with significant positive societal consequences. Recent work in social neuroscience has linked empathy for pain and suffering to particular set of neural regions, including the dorsal anterior cingulate and bilateral anterior insula. However, people do not always respond to others in pain. In fact, people often ignore the suffering of individuals outside of their purview. Extant cognitive theories suggest that psychological distance may help explain when an individual might fail to empathize with others' suffering. Such theories suggest that individuals will respond more robustly to proximal suffering - pain that seems nearby or recent - than more distal suffering - pain that occurs on the other side of the world or in the distant past. Indeed, people donate more after natural disasters that occur close to home than further away, and those donations taper off as the disaster falls further into the past. To test the extent to which spatial and temporal distance diminishes empathy, we measured spontaneous neural responses using fMRI scanning while participants watched video clips of two target individuals suffering painful experiences. The two targets differed in their spatial and temporal

proximity to the participant: participants believed one set of videos was being recorded live and in a room down the hall from the scanner (proximal target); the other set of videos was previously recorded at a distant location (distal target). Both whole-brain and region-of-interest analyses revealed greater dACC and insula responses while watching suffering by the proximal target than by the more distal target. Additional analyses explored the extent to which individual differences in neural responses to the proximal and distal target correlated with implicit measures of psychological distance between the proximal and distal target. Together, such findings suggest that empathic responses diminish as individuals perceive the target of suffering to be further away in spatial and temporal distance.

Abstract: Given the importance of perspective-taking, empathy and intention understanding to human sociality, it might be argued that the neural correlates of these would be engaged automatically. Indeed, some have suggested that social mirroring in the brain may be automatic and involuntary. Using a putative electroencephalographic measure of human mirror neuronal processing, mu rhythms, we tested the hypothesis that cognitive distraction would attenuate mu suppression. We also correlated mu suppression with the Empathy Quotient and the subscales of the Interpersonal Reactivity Index to determine whether previous research showing such correlations could be replicated. The first hypothesis was confirmed in that, while watching a video of hand movements, a secondary word generation distraction task eliminated evidence of mu suppression relative to a focused attention. These findings strongly indicate that mirroring processes as measured by mu suppression are not obligatory but require focused attention. Previous research indicating negative relationships between empathy and mu suppression were also replicated. A model to explain the seemingly counter-intuitive negative relationship is offered.

Title: Physicians activate their own brain regions for pain relief and reward while treating patients

Authors: *K. JENSEN[1], P. PETROVIC[2], C. KERR[3], I. KIRSCH[4], J. RAICEK[5], A. CHEETHAM[5], R. SPAETH[5], A. COOK[5], R. GOLLUB[5], J. KONG[5], T. KAPTCHUK[4]

Abstract: Background: Patient-physician interactions significantly contribute to placebo effects and clinical outcomes. While the neurobiology of unspecific treatment effects have been studied in patients, the neural correlates of the *clinician* during treatment is unknown. Here, we investigated the neural correlates of physicians during treatment of patients, combined with ratings of treatment satisfaction and empathy-related measures.
Methods: Using functional magnetic resonance imaging (fMRI), we measured physicians' brain activations during analgesic treatment of patients in pain. The physician was placed in the brain scanner and equipped with a device that could activate patient analgesia. The patient was sitting next to the scanner, facing the physician.
Results: Physicians' reported significant levels of satisfaction during 'treatment' ($p<.05$) and strong dissatisfaction during a 'no-treatment' condition ($p<.001$) in which they passively watched the patient in pain. Brain regions implicated in expectancy for pain-relief and increased attention were activated in physicians during treatment, including the ventrolateral and dorsolateral prefrontal cortices. The physician's ability to take the patients' perspective correlated with brain representations of reward and subjective value, as reflected in the rostral anterior cingulate cortex. During the 'no-treatment' condition, physicians displayed empathy-for-pain related activations in the right anterior insula.
Conclusions: Our data suggests that physicians activate their own brain regions for pain relief and reward during administration of patient analgesia, paired with increased attention

activations. Our findings further the understanding of the neural representations associated with reciprocal interactions between clinicians and patients, which is a hallmark for successful placebo-responses.

Title: Congruent map between the kinesthetic and the visual perceptions of our physical movements, even with noise

Authors: *G. JOHNSON, P. YANOVICH, G. DIFEO, L. YANG, E. M. SANTOS, N. ROSS, E. B. TORRES
Psychology, Rutgers Univ., Piscataway, NJ

Abstract: The information derived by perceiving and decoding gestures and movements underlies our social interactions, allowing us to infer intentionality, or to anticipate future actions from even subtle cues. Links between less intentional components of our movements-those occurring below our awareness-and social judgments are also important, but widely underexplored. We ask whether the movement percept emerging from our kinesthetic sensation of physical movements aligns in any way with the movement percept visually sensed when observing the motions of others. Here we designed experimental methods and objective metrics to gain insight into these issues. First, the physical movements of expert athletes with skilled timing in performing a tennis serve and a martial arts routine were recorded, then those of novices performing these routines as well. To have a broad range of typical noise, we manipulated sensory feedback during recording by performing in the dark, in front of a mirror, with glowing sticks in the dark reflected in a mirror, and others. For each individual, the patterns of variability of the time to reach their peak angular velocity for each accessible joint of the body, taken across hundreds of repetitions, were extracted. The parameters defining the personal stochastic signatures of each individual using the Gamma distribution family were then obtained. Using maximum likelihood estimation (MLE), the shape and scale parameters corresponding to the variability of the dynamics of each joint were estimated and plotted as points of the Gamma plane. We then built an avatar, and endowed the avatar with both the veridical motions of the subjects and also with noisy variants thereof. To create the avatar, we used the noise from the subjects' own stochastic signatures, the noise from those of others, and also we drew noise from the Exponential and the Gaussian distributions, which we had previously identified in the physical movements of autistic males and females. The experts and novices then performed a perceptual task where they decided, for each variant of the avatar, whether or not they were viewing themselves by pointing and touching a screen. We measured their movement decision time, and also extracted their stochastic signatures as above. The points were plotted on the Gamma plane and we found that, despite the noise, the timing of our visual motion perception aligns well to the timing of our kinesthetic perception of our actual physical movements. This relation, as it turns out, is well characterized by a power law.

Title: Both physical and non-physical similarity modulate neural activity during imitation: Effects of political ideology and race

Authors: *E. A. REYNOLDS LOSIN[1], M. IACOBONI[2], M. DAPRETTO[2]
[1]Interdepartmental Neurosci. Program, Univ. of California, Los Angeles, CA; [2]Psychiatry and Biobehavioral Sci., UCLA, Los Angeles, CA

Abstract: Political ideology is an influential social category based on the way people *think*, yet it has many things in common with social categories like race, based on the way people *look*. One such commonality is that both types of social groupings influence whom people imitate. We have previously found that the neural systems underlying imitation are modulated by the physical characteristics of the person being imitated (the model), including his or her race. Here we tested whether political ideology, a category with no physical manifestation, modulates brain activity during imitation and whether this modulation is influenced by race, a social category accompanied by perceptual cues.

We used a functional MRI paradigm in which 17 highly liberal individuals imitated liberal and conservative actors performing novel hand gestures. In order to investigate the interaction of political ideology and race, actors were evenly divided among three racial groups [European American (EA), African American (AA) and Chinese American (CA)], while all participants were all EA. Critically, participants learned fictitious information about actors' political beliefs prior to scanning and no indication of an actor's political ideology was available during the imitation task.

The anterior cingulate cortex (ACC) and neighboring medial prefrontal cortex (MPFC) – regions not previously found to be modulated by a model's race – were more active during imitation of political outgroup compared to ingroup members. This result demonstrates that different characteristics of a model are encoded by different neural systems during imitation. We next examined the (imitate political outgroup > ingroup) contrast for actors of different races. We found evidence of a political ideology x race interaction such that increased activity for political outgroup members, in a more ventral part of the ACC/MPFC, was significantly greater when imitating racial ingroup members (EA) compared to racial outgroup members (AA or CH). These data suggest that information about the model's non-physical characteristics (i.e. political ideology) may be more influential for those most similar to the self in physical characteristics (i.e. race). Finally, this political ideology x race interaction was also observed in the lateral fronto-parietal and visual regions we previously found to be modulated by a model's race. Taken together, these findings suggest that social categories modulate neural activity during imitation even in absence of perceptual cues. Furthermore, they suggest that the neural encoding of social

categories associated with perceptual cues, such as race, may be altered by non-perceptual information.

Title: Behavioral and neural evidence for an associative account of stereotype formation

Authors: H. J. SPIERS[1], *B. C. LOVE[1], C. GIBB[1], M. E. LE PELLEY[2], R. A. MURPHY[3]
[1]Cognitive, Perceptual and Brain Sci., Univ. Col. London, London, United Kingdom; [2]UNSW, Sydney, Australia; [3]Univ. of Oxford, Oxford, United Kingdom

Abstract: There is strong evidence that aspects of human learning, like conditioning, involve error-driven learning. Can aspects of stereotype formation in which minority groups are viewed less favorably also be explained by such learning mechanisms? Our work on the illusory correlation in stereotype formation is consistent with predictions generated by models like that proposed by Rescorla-Wagner (1972). As with the original illusory correlation (IC) effect demonstrated by Hamilton and Gifford (1974), people learning about fictitious social groups form an illusory correlation between group membership and the affective value of behaviors attributed to the group members. Consistent with the associative model predictions, IC seems to be a pre-asymptotic learning effect (Murphy, Schmeer, Vallee-Tourangeau & Hilton, 2010). A further prediction of the associative account is that this learning is the result of an error correction principle guided by a negative evaluative response. Using recent work on the localization of these aspects of brain function we used functional magnetic resonance imaging (fMRI) to explore this prediction. Results support the characterization of IC as the product of an associative process. Eighteen subjects were scanned with fMRI with a 1.5T scanner. SPM8 GLM analysis revealed that anterior striatum (pallidum) was more active for minority groups than majority groups when all trials were compared. In an additional analysis, the Rescorla-Wagner

model was fit to subjects' behavioral data and quantities from this model were entered into the GLM as model-based regressors. Of primary interest was the model's trial-by-trial predicted affective response for an item. Bilateral anterior temporal pole activity was correlated with this measure that captures affective response to the group names. These results clarify the role that the anterior temporal pole plays in social and emotional processing (cf. Olson, Plotzker & Ezzyat, 2007).

Title: Robust selectivity for faces in human amygdala

Authors: *P. MENDE-SIEDLECKI, S. C. VEROSKY, N. B. TURK-BROWNE, A. TODOROV
Princeton Univ., Princeton, NJ

Abstract: Single-unit recordings have identified neurons that respond selectively to faces in inferotemporal (IT) cortex and the amygdala. Functional magnetic resonance imaging (fMRI) has replicated these findings in cortical regions, showing elevated blood-oxygen level dependent (BOLD) responses to faces in both monkeys and humans. However, the face selectivity of the amygdala remains uncharacterized. Prior fMRI studies relied on localizer tasks in which participants are presented with photographs of faces and objects from other visual categories (e.g., houses) to identify face-selective BOLD responses. Here we show that the discrepancy in the face selectivity of neuronal and BOLD responses in the amygdala results from limited statistical power in the standard localizer approach. First, the amygdala's small size and location make it difficult to image because of a reduced signal-to-noise ratio relative to cortical regions. Second, group analyses of localizer data are not typically reported to avoid cortical

misalignment, which compounds the problem because of increased measurement error. To overcome these challenges, we performed group analyses of functional localizer data from more than 200 human participants. These data were collected as part of 10 studies, using various behavioral tasks and visual control categories. Beyond the posterior network of cortical regions observed in prior studies, we found robust face-selective responses in the amygdala. In addition, the pattern of responses to faces across amygdala voxels had high reliability over time. Finally, examining the covariance of these reliability scores across face-selective regions revealed separable cortical and subcortical face-processing networks. These results bridge an extant gap between single-unit recording and neuroimaging studies, suggesting that the amygdala has comparable face selectivity to putative "face" areas in posterior visual cortex. This provides some of the first evidence that subcortical regions can be specialized for high-level cognitive processes.

Title: The social contagion of itch

Authors: *J. WARD[1], A. SETH[1], H. CRITCHLEY[1], K. WARNE[1], H. HOLLE[2]
[1]Univ. of Sussex, Brighton, United Kingdom; [2]Univ. of Hull, Hull, United Kingdom

Abstract: Watching someone scratching themselves can elicit subjective sensations of itchiness in the perceiver - this is a form of sensori-motor contagion. In this fMRI study participants watched movies of someone itching themselves versus control movies of tapping the same body part and participants also rated their subjective itchiness. Observing itching (relative to tapping) movements activated most major areas implicated in the veridical perception of itch, including the thalamus, primary somatosensory cortex (BA2), premotor cortex (BA6) and the insula. This suggests a shared system between the veridical perception of itch and the social perception of itch - analogous to that reported for pain. Whereas the observer of pain does not typically report

painful sensations from observing pain, the same is not true for itch. Most people report subjective sensations of itchiness during the itch trials and the intensity of these sensations correlated with the BOLD response in many of the key regions. In addition, individual differences in 'itch contagion' were positively correlated with the personality dimension of agreeableness (but not empathy) and this dimension also correlated with the degree of activity within the primary somatosensory cortex.

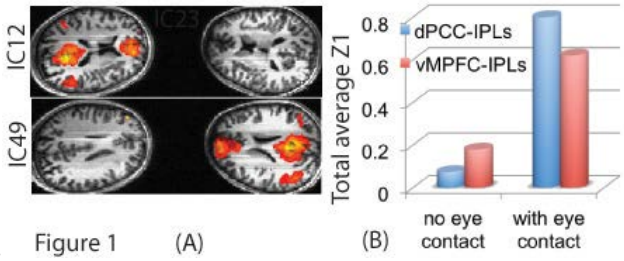
Title: A dyadic fMRI (dfMRI) study on quantifying the default-mode network's response to social interaction



Authors: *R. LEE
Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: INTRODUCTION: Dyadic fMRI (dfMRI) (1) can directly quantify the social interaction at the brain network level. In the presence of the same sampling environment, the dependency among the activated regions in dyadic brains can be mathematically defined by ICA which provides a platform to simultaneously observe multiple brain networks' responses during social interaction. In this study, the dyadic default-mode network (DMN)'s response to eye contact is quantitatively characterized.
METHODS: The dfMRI hardware, protocols, and the eye-contact experiment design, are detailed in the Ref. (1). The dyadic data is first preprocessed with in-house Matlab codes. Then using ICA (FSL's MELODIC) generates a set of independent components (IC). The ICs containing DMN are selected as masks to extract the time series from four DMN nodes: PCC, MPFC, left and right IPL. The correlations between the four nodes are calculated; and their correlation differences are tested by Steiger's Z1 and Z2 (3).
RESULTS: 20 pairs of subjects were studied. Three of the major findings regarding DMN are: (i) Any two subjects' DMNs are always independent, as in Fig. 1A. The DMN of one can be coupled with other's non-DMN networks, but no DMN-DMN coupling was observed. (ii) Eye contact causes left-right asymmetry in a subset of DMN (dosal PCC, ventral MPFC, left and

right IPL). Using Steiger's Z1 to test both differences in correlation r(dPCC, lIPL) vs. r(dPCC, rIPL) and in correlation r(vMPFC, lIPL) vs. r(vMPFC, rIPL), the average asymmetry scale (Z1) due to eye contact is shown in Fig. 1B. (iii) If Steiger's Z2 is used to describe the DMN modulations due to eye contact, and the coupling between the DMN of one brain and the other brain is defined as the sum of square of all crossing brain correlations, then the coupling is a function of both Z1 and Z2.

CONCLUSION: Certain aspects of social interaction can be directly quantified by measuring asymmetry, modulation and coupling of the DMN.

Title: Medial prefrontal cortex and the emergence of self-conscious emotion in adolescence

Authors: *L. H. SOMERVILLE[1], R. M. JONES[2], B. J. CASEY[2]
[1]Psychology, Harvard Univ., Cambridge, MA; [2]Sackler Inst., Weill Cornell Med. Col., New York, NY

Abstract: Adolescence is a time of life associated with heightened self-consciousness and arousal in social contexts. The current study sought to evaluate whether developmental differences in the sensitivity of social-cognitive brain circuitry parallel this behavioral trend. Participants ranging from 8 to 22 years of age underwent a simulated social evaluation task during fMRI and skin conductance recording. During certain blocks, participants believed a

hidden video camera was projecting their image to be viewed by a peer in real-time (evaluation condition), and during other blocks participants waited for the camera to turn on (anticipation condition). Analyses focused on a) identifying adolescent-specific effects paralleling behavioral findings using age as a continuous variable and b) testing such effects for specificity to evaluation versus anticipation conditions. Adolescents showed heightened embarrassment and skin conductance to anticipation and evaluation periods compared to children and adults. This was paralleled by adolescent-selective engagement of the medial prefrontal cortex (MPFC) both while anticipating and being the target of evaluation, and stronger MPFC-striatal connectivity in adolescents. Taken together, these findings suggest that sensitization of social-cognitive brain circuitry and connectivity between social-cognitive and reward systems support the heightened propensity for adolescents to experience self-conscious emotion.

Title: Differential neural processing of guilt and regret

Authors: *U. WAGNER, H. WALTER
Dept. of Psychiatry and Psychotherapy, Div. of Mind and Brain Res., Charité - Univ. Med. Berlin, Berlin, Germany

Abstract: Human decision making critically relies on the ability to weigh expected outcomes of choices. In addition, humans use counterfactual thinking in order to evaluate their choices in hindsight, comparing the actual outcome of a choice with what would have happened if they had chosen another action option. Two prototypical emotions resulting from such counterfactual evaluations are guilt and regret, both of which are thought to play an important role in regulating human behavior. Empirical studies asking people to describe typical situations of guilt and regret found that guilt specifically occurs for choices in social (interpersonal) contexts, while regret occurs for individual (intrapersonal) choices more or to the same degree as for social choices. However, little is known how this psychological distinction is represented in the brain. Here, extending existing decision-making paradigms used for the neuroscientific investigation of

intrapersonal regret, we developed a method to distinguish guilt and regret and their neural underpinnings (using fMRI) by systematically inducing these emotions under controlled conditions. Healthy human subjects choose in each trial between one of two lotteries, with the outcome of the chosen lottery (win or loss) either assigned to the self (individual choice condition) or to another person (social choice condition). Behavioral results confirm that guilt but not regret specifically occurs in a social context (i.e. after losses for another person resulting from one's own choices). On the neural level, initial results point to a critical role for the dorsomedial prefrontal cortex and the subgenual anterior cingulate cortex in differentiating the two types of negative emotional experiences.

Title: Prefrontal cortical neuronal activity during an automated operant set shifting task in rats

Authors: A. DEL ARCO[1,3], Y. KIM[1], J. WOOD[1], B. MOGHADDAM[1], *C. W. BRADBERRY[2]
[1]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [2]Psychiatry, Univ. of Pittsburgh, PITTSBURGH, PA; [3]Physiol., Univ. Complutense, Madrid, Spain

Abstract: The activity of neurons in the prefrontal cortex (PFC) is critical for learning, representing, and maintaining rules which guide behavior. However, when rules change it is uncertain whether prefrontal neurons respond to transitions between rules or they encode rule shifting *per se*. We recorded single unit activity in the medial PFC (prelimbic cortex) during an operant set shifting task in which animals had to perform several shifts between two rules in the same session. The rules presented were based on two perceptual dimensions: illumination (light) and spatial location (side). Specifically, male Sprague Dawley rats were trained to poke in one of the three nose holes of an operant chamber according to a light rule (illuminated hole) or a side rule (right, center or left hole regardless illumination) to get the reward (sugar pellet). Incorrect trials still required the animal to poke the pellet trough, though the reward was not delivered (sham reward poke). The session finished when the animal successfully performed 3 shifts between 4 sets. A shift between sets occurred after 10 consecutive correct responses. Animals

had to adopt the current rule by trial and error based on the delivery or omission of reward after each trial. During the recording sessions, performance was stable and animals required 169 ±6 trials to complete the task, making 48 ±2 total errors and 28 ±1 perseverative errors per session. Different subpopulations of units encoded various task components. A majority of units increased discharge rate between 1500 and 500 ms before the instrumental poke (preparatory activity). The discharge of some of these units increased or decreased their firing rate after the set shifts. In addition, distinct subpopulations of units increased their activity after the instrumental poke during reward delivery or sham reward pokes, corresponding to correct or incorrect responses. Ongoing analyses are examining the trial-by-trial modulations of single units and population activity. Supported by National Institute of Health.

Title: Effects of NMDA, mGlu2/3, and mGlu7, receptor antagonism in the rat medial prefrontal cortex on performance in the 5 choice serial reaction time task

Authors: *A. BENN, E. S. J. ROBINSON
Physiol. and Pharmacol., Univ. of Bristol, Bristol, United Kingdom

Abstract: Disrupting glutamatergic function in the medial prefrontal cortex (mPFC) of rats has previously been shown to induce performance deficits in animal models of cognition and executive function including, the 5 choice serial reaction time task (5CSRTT). In this study we investigated the effects of blockade of NMDA receptors (NMDAR), and metabotropic glutamate receptors (mGluR) associated with regulating glutamate release, the mGluR2/3 and mGluR7 subtypes, in the mPFC. We also tested animals trained in a non-paced version of the 5CSRTT designed to increase attentional load.
Male Lister-Hooded rats (350-450g, n=6-10) were trained to a stable performance level before being implanted with mPFC guide cannula. Each animal received prelimbic (PL) then infralimbic (IL) infusions. Drug doses were MMPIP (a negative allosteric modulator at mGluR7 located within the active zone), 0.0, 0.1, 1.0 µg/µL, MK801 (non-competitive NMDAR

antagonist) 0.0, 3.0, 10.0 µg/µL, and LY341495 (orthosteric antagonist at mGluR2/3 expressed away from the active zone in pre-terminal axon regions) 0.0, 0.3, 1.0, 10.0 µg/µL.
Our results show that MMPIP impaired accuracy [F(2, 18)=4.75, p=0.022, 1.0µg/µL versus vehicle p=0.010] when infused into the PL cortex but not IL cortex, with no effect on omissions or premature responses in either brain region. MK801 increased premature responses when infused into the IL cortex [F(2, 10)=11.75, p=0.002, 3.0µg/µL p=0.038 and 10.0µg/µL p=0.002], and tended to increase premature responses in the PL cortex [F(1.1, 8.6)=3.45, p=0.096]. Accuracy and omissions remained unaffected in either brain region. LY341495 had no effect on performance variables in any brain region.
Our results show that disruption of mGluR7 but not mGluR2/3 selectively impairs accuracy when infused into the PL cortex, an area thought to mediate goal-directed behaviour. We surmise that accuracy in this task requires proper functioning of mGluR7 located in the active zone of neurotransmitter release, and not glutamate receptors located perisynaptically (mGluR2/3). Similar to previous studies, NMDAR antagonism in the IL cortex increased premature responding although accuracy was not affected by treatment targeted at the PL cortex. This difference may be due to the use of a non-paced version of the task. We conclude that disruptions to glutamate transmission cause differential effects on attention and impulse control depending on the receptor subtype and brain region involved.

Title: Shared neural mechanisms for bottom-up and top-down control of spatial attention

Authors: *S. P. MYSORE, E. I. KNUDSEN
Neurobio., Stanford Univ., STANFORD, CA

Abstract: Operating in complex environments, animals must select the most important among competing stimuli to pay attention to at any instant. Both the physical properties of stimuli (bottom-up signals) and their behavioral relevance (top-down signals) contribute to stimulus “priority” in this competitive selection. However, whether bottom-up and top-down signals operate via shared or distinct neural mechanisms to influence competition is unclear. Here, we

investigate this question in the barn owl using visual and auditory stimuli to invoke competing bottom-up signals, and electrical microstimulation of the forebrain gaze field to invoke space-specific top-down signals. We demonstrate that focal and reversible inactivation of a GABAergic midbrain nucleus, the Imc, abolishes both bottom-up and top-down mediated competitive suppression of responses in the optic tectum, a midbrain structure known to be essential for normal selection behavior in attentional tasks. Our results reveal novel insights into the neural mechanisms that control spatial attention.

Title: General anesthesia is reversed by electrical stimulation of midline areas of midbrain and thalamus

Authors: *K. D. ONOS, S. R. STEVENS, B. A. WORMWOOD, R. G. MAIR
Psychology, Univ. of New Hampshire, Durham, NH

Abstract: General anesthesia is associated with suppression of thalamic activity. Previously we reported that rats can be aroused from general anesthesia by electrical stimulation of midline thalamus, a result consistent with effects of pharmacological stimulation of this site (Alkire et al., 2009, Anesthesiology 110:766-773). Here we compared the effects of stimulation in midline thalamus to a control site located in the area of the rostral linear raphé nucleus. Bipolar stimulating electrodes (twisted pairs of 0.125 mm SS wires with polyamide insulation, PlasticsOne) were implanted in midline thalamus or the control site. Isoflurane anesthesia was induced until rats showed no toe-pinch response and were inactive during a 3-minute stabilization period (0.75 to 1.0 % in 5 L/min of O2). Rats were then placed on their backs in a sleep trough and anesthesia administered at constant rate and concentration through a nose cone. Constant current electrical stimulation (a 10 s train of 0.2 ms pulses @ 120 Hz) was delivered through a stimulus isolator (A 365, WPI) driven by a Pulsar stimulator (FHC). Current levels were increased from 1 microA to 3 mA with a 60 s observation after each stimulation. Each animal underwent 3 days of testing that were videotaped. Surprisingly, we found the control site was more effective reversing the effects of anesthesia. All controls (8/8) showed full arousal on at least one of the three testing days with full arousal (active attempt to escape from nose cone)

on 20/24 (83%) of test sessions and isolated movements of extremities on 24/24 (100%) sessions. By contrast only 6 of 11 rats in the thalamic group showed full arousal on at least one test day with full arousal on 7/32 (22%) of test sessions and isolated movement of extremities on 26/32 (81%). This confirmed our previous results in which 6 of 10 animals righted (from a flat surface) with comparable midline thalamic stimulation. There was no difference between the groups for the level of stimulation necessary for arousal. These results indicate that midline thalamus is not unique as a site where electrical stimulation can reverse general anesthesia. It seems more likely that anesthesia can be reversed by stimulation of a distributed neural network that includes midline areas of brainstem and thalamus.

Title: Response latencies of error detecting signals dissociate anterior cingulate and prefrontal contributions for performance monitoring and outcome predictions

Authors: *C. SHEN[1], D. KAPING[1], S. ARDID[1], S. EVERLING[2], T. WOMELSDORF[1]
[1]York Univ. Ctr. For Vision Res., Toronto, ON, Canada; [2]Western Univ., London, ON, Canada

Abstract: Performance monitoring refers to the continuous process of outcome evaluation and becomes particularly apparent when errors or unexpected outcomes occur. Neuronal activities signaling errors and evaluating the outcomes of choices have most prominently been found in the anterior cingulate cortex (ACC), with similar signals reported within more lateral subdivisions of the prefrontal cortex (lPFC). It remains unclear, however, whether error detecting signals in ACC/lPFC are distinguishable.
We therefore examined error-related (ER) single neuron activities across a large extent of the lPFC/ACC of two rhesus monkeys during a selective attention task that contained errors across different task epochs (Kaping et al., PLoS Biol 2011). ER firing rate modulation was quantified in successive ± 0.15 sec. windows around the time of error commission. Among n=649 recorded

neurons, 26% (n = 170) showed significant ER firing rate modulation and were further analyzed. The proportion of ER neurons varied across time with separable populations of neurons showing early onset latency of error modulations ≤0.10 sec. (~29%), and late onset latency of error modulations around 0.20 and 0.45 sec. following error commission (~37% / ~34%, respectively). Early onset error signals were particularly prominent in the lPFC while error signals emerging ≥0.2 sec. clustered anatomically in the ACC. We next tested whether ER neurons distinguished errors committed (i) during sustained selective attention on a stimulus (indicative of motivational lapses), (ii) around the time when a salient distractor occurred (indicative of faulty attentional capture), or (iii) during a perceptual choice about the rotation direction of a stimulus. We found that the largest subset of neurons (>30%) coded for errors in at least two task epochs, with only few neurons signaling errors committed solely during focused attention or during the distractor period (both < 5%).
These findings reveal that the latency of error detection distinguishes ER neuronal signals within the ACC and lPFC, suggesting that the later onset ER signals in ACC reflect the integration of outcome signals from the lPFC. In summary, these findings support the unique role of the ACC to encode outcome predictions (Alexander & Brown Nat Neurosci 2012) and suggests that error coding in the ACC can be instrumental as learning signals to improve choices and attentional deployment in trials subsequent to error trials (Bryden et al. J Neurosci 2011).

Title: Distinct behavioral and neurophysiological correlates of prefrontal acetylcholine and glutamate transients during attentional task performance.

Authors: *W. M. HOWE, H. GRITTON, N. LUSK, J. BERKE, M. SARTER
Univ. of Michigan, Ann Arbor, MI

Abstract: Transient increases in medial prefrontal (mPFC) acetylcholine (ACh) release aid the detection of behaviorally relevant cues during attentional performance (Parikh et al., 2007). These cholinergic transients are generated locally and require cue-evoked glutamate release from mediodorsal thalamic afferents (Parikh et al., 2008, 2010). Attentional performance is also associated with gamma oscillations within the mPFC. Here we investigate the relationships between each of these processes during attention task performance. Rats were trained to discriminate trials with a short, unpredictable visual cue from cue-absent trials by pressing one of two levers extended into the operant chamber. We monitored release of acetylcholine and glutamate using fixed-potential amperometry and enzyme-coated microelectrodes placed in the thalamic input layer of mPFC. Both glutamatergic and cholinergic transients were evoked by visual cues that were detected (hits), but not by cues that were missed. During misses or non-signal trials yielding correct rejections, glutamatergic transients were also evoked by lever extension, suggesting glutamate transients are associated with the processing of stimuli that evoke behavioral responses or decisions. Cue detection and lever extension were also associated with a corresponding increase in gamma-power. Cholinergic transients were evoked by cues in trials yielding hits but only if such signal trials were preceded by non-signal trials or misses ("incongruent hits"). Thus, cholinergic transients are hypothesized to mediate shifts between ongoing processing and cue-directed attention and behavior. Compared to successive hits, incongruent hits, which evoked both glutamatergic and cholinergic transients, were associated with greater gamma power coincident with cue detection. This augmentation may support shifts in attentional processing modes by optimizing interactions across widespread cortical and subcortical networks. Combining the recording of second-based neurotransmitter release with local field potentials reveals the contributions of individual afferent systems and local circuitry to fundamental cognitive operations.

Title: Effects of orexin A administered into the basal forebrain on attentional performance in rats

Authors: *K. N. ZAJO[1], J. R. FADEL[2], J. A. BURK[1]
[1]Psychology, Col. of William & Mary, Williamsburg, VA; [2]Pharmacology, Physiol. and Neurosci., Univ. of South Carolina Sch. of Med., Columbia, SC

Abstract: The neuropeptides, orexins, are released from neurons that are primarily localized in the lateral hypothalamus and contiguous perifornical area. The basal forebrain, among other regions, receives orexinergic projections. Normal attentional processing requires the integrity of the basal forebrain in rats. Our previous research demonstrated that orexin receptor blockade impairs attention and that infusions of orexin A into the lateral ventricle enhances attentional performance. The goal of the present experiment was to test whether the basal forebrain mediates the attention-enhancing effects of orexin A. Male FBNF rats were trained on a sustained attention task that required discrimination of visual signals (500, 100 or 25-ms illumination of a centrally located panel light) from trials when no signal was presented. After stable performance levels were established, rats received guide cannulae implanted bilaterally into the basal forebrain. Postsurgically, rats were trained in a version of the task in which attentional demands were augmented by presenting a visual distracter during the middle block of trials. Rats then received 0 (vehicle), 0.1, 1.0 or 10.0 pM orexin A prior to task performance. Each rat received each dose once in a counterbalanced order. Accuracy tended to be higher during the first block of trials following vehicle administration compared with orexin A administration. However, attentional performance decreased from block 1 to block 2, when the distracter was presented, following vehicle treatment. This distracter-induced impairment in accuracy was attenuated following administration of higher orexin A doses. These findings suggest that intrabasalis orexin A administration blocks sensitivity to the distracter during the second block of trials. These results provide additional support that orexin A can enhance attentional processing and suggest that the basal forebrain may be one important neural substrate that mediates these effects.

Title: Not all cues are equal: Neurochemical and functional-imaging measures reveal neuronal mechanism connecting cues to internal representations

Authors: *A. S. BERRY[1], W. M. HOWE[1], J. FRANCOIS[2], S. LOOMIS[2], G. GILMOUR[2], C. LUSTIG[1], M. SARTER[1]
[1]Univ. of Michigan, Ann Arbor, MI; [2]Eli Lilly, Surrey, United Kingdom

Abstract: Successful goal directed behavior involves shifts between ongoing activity and the processing of instructional external cues (or signals). We investigated the neural mechanisms underlying cue-directed processing shifts using a translational, cross-species sustained attention task (SAT). This task consists of long variable-duration monitoring periods during which a signal (visual stimulus) may or may not occur, followed by a prompt to report the prior presence (hit/false alarm) or absence (miss/correct rejection) of a signal. These long monitoring periods as well as the unpredictable distribution of non-signal and signal events lead to stable ongoing processing (monitoring and committing correct rejections) with intermittent periods of signal-directed behavior (hits). To examine the neural mechanisms of breaks from ongoing processing to signal-directed behavior, we examined transient changes in prefrontal acetylcholine levels in rats and transient fMRI BOLD activations in humans during “shift-hits,” that is, correct signal detections (hits) preceded by CRs or misses. Neural activity on shift-hit trials was contrasted with activity associated with non-signal responses (CRs and misses), and with hits that followed another hit. Cues in shift-hit trials, but not during successive hits, evoked transient increases in cholinergic activity. In humans, the same shift-hits were associated with transient activation in a region of right rostral prefrontal cortex (BA 10). To further link these findings, we measured prefrontal oxygen levels in task-performing rats, again finding increases specifically evoked by cues in shift-hit trials. Further, stimulation of cholinergic receptors was sufficient to evoke oxygen responses comparable to those seen during shift-hit trials. Together, these parallel and converging findings from human and animal experiments reveal a prefrontal mechanism involved in connecting cues to internal representations. Further, we demonstrate that the cholinergic system is integral to this operation and may underlie the BOLD response observed in humans.

Title: Learning expected stimulus values in a selective attentional foraging task by nonhuman primates

Authors: *M. BALCARRAS[1], S. ARDID[1], D. KAPING[1], S. EVERLING[3], T. WOMELSDORF[2]
[2]Dept of Biol., [1]York Univ., Toronto, ON, Canada; [3]Dept. of Physiol. and Pharmacology, Dept. of Psychology, Western Univ., London, ON, Canada

Abstract: Goal-directed behavior depends on covert attentional selection of stimuli prior to overt choice behavior (Rangel & Hare, Cur Opin Neurob 2010). In order to optimize future choices to achieve maximal positive outcome it is necessary to assign experienced outcome values not only to the correct action, but also to the stimulus that was selected prior to the overt choice. Reinforcement learning frameworks and value based decision making theories suggest that humans are often near optimum in their credit assignment based not only on action values, but also based on more abstract stimulus values. Very little is known, however, about stimulus value coding in primates as commonly used paradigms typically do not dissociate stimulus from action valuations.

We therefore devised a selective attentional foraging task in which two rhesus monkeys were trained to flexibly learn the expected values of stimuli and discount action values that were linked to a two-alternative forced-choice decision performed on the previously selected stimulus. We analyzed choice behavior of 46 sessions entailing 396 blocks of trials with novel stimulus value assignments. Overall, the animals learned to guide covert attentional choices in > 90% of blocks based on the intrinsic compiled stimulus value, discounting action values and time delays beyond 1.5 sec. The learning rate of the expected correct stimulus value approached an avg. of 11-12 trials, revealing a rapid credit assignment of stimulus related outcomes, albeit slower than the corresponding assignments of action related outcome values. In one animal we tracked initial learning of the task across days, identifying a tendency to erroneously assign values to immediate actions early during learning and a smooth increase of learning rates after progressive experience in the task.

These findings demonstrate that nonhuman primates optimize choice behavior by an internal learning process that represents the expected value of a basic sensory feature. The rapid learning rates reveal that the selective attentional foraging task successfully tracks the “learning of attention” within few trials, allowing in the future to study the neuronal correlates of how top-down attentional control processes emerge during task performance.

Title: Neural mechanisms of visual selection in prefrontal cortex, FEF, and IT cortex during a free-viewing search task

Authors: N. P. BICHOT, M. T. HEARD, *R. DESIMONE
MIT, McGovern Inst. Brain Res., CAMBRIDGE, MA

Abstract: To investigate the neural systems mediating the ability to find relevant objects in crowded scenes based on their visual features, we trained two monkeys to perform a free-viewing visual search task. After fixating a central fixation spot, monkeys were presented with a central cue showing the target stimulus for that trial. The cue was extinguished after 1 s, and the fixation spot reappeared for 800 ms. Monkeys were required to hold fixation at the center of the screen during this period, after which time the search array was presented. Monkeys had 10 s from search array onset to find the target, and no constraints were placed on their eye movements so that they could conduct the search naturally. When the monkeys found the target, they fixated it for 800 ms continuously. We used a fixed set of eight natural object stimuli throughout the study. On each trial one stimulus was chosen as the target, and the remaining seven stimuli were distracters. Stimuli were positioned at eight of the twelve possible locations, and the target location and identity were chosen pseudo-randomly from trial to trial. Multi-unit spike activity and local field potentials were recorded in three areas: 1) IT cortex, which plays a central role in the recognition of natural objects such as those used in this study, 2) FEF, which plays a key role in visual spatial selection, and 3) area 45 of prefrontal cortex (PFC) which has been shown to play an important role in working memory and executive control.
The responses of IT neurons were enhanced shortly before a saccade to a preferred target object in their receptive field (RF). In contrast, while FEF neurons did not respond selectively to the different objects, their responses to targets in their RF were enhanced compared to distracters, with a latency of about 100 ms, which was earlier than the enhancement observed in IT. Most interestingly, neurons in PFC signaled both cue information and the location of the target in their

RF. PFC responses were enhanced prior to search array presentation when the neurons' preferred object was the cue, and this enhancement persisted throughout the trial whether the animals made a saccade to the target or a distracter. Furthermore, when the target was in their RF, the activity of PFC neurons increased to signal its location within 100 ms of search array presentation, similar to the time course of selection in FEF. These results suggest that PFC encodes target properties and locates the target stimulus and feeds this information to FEF. FEF, in turn, may feedback a spatial selection signal to IT cortex and earlier visual areas.

Title: Attentional modulation of spike-phase coupling in theta band of local field potentials in mt area of the macaque cortex

Authors: M. ESGHAEI[1], M. SARAF[1], L. BUSSE[2], S. TREUE[3], *M. DALIRI[4]
[1]Sch. of Cognitive Sci., Inst. for Res. in Fundamental Sci. (IPM), Tehran, Iran, Islamic Republic of; [2]Ctr. for Integrative Neurosci., Univ. of Tuebingen, Tuebingen, Germany; [3]Cognitive Neurosci. Lab., German Primate Ctr., Goettingen, Germany; [4]Iran Univ. of Sci. and Technol., Tehran, Iran, Islamic Republic of

Abstract: Visual attention decreases the interneuronal correlation in the visual cortex. Furthermore, switching attention between two locations changes both the amplitude and phase of local field potentials (LFPs) recorded from the corresponding area of the cortex in low frequency bands(Fries et al., 2001; Lakatos et al., 2008). We also know that in many areas of the brain, spike times are modulated by the phase of LFPs at low frequency bands (<10 Hz). However, any attentional modulation of the relationship between spike times and the phase of low frequency LFPs is still largely unexplored.
In the current study, we recorded both spikes and LFPs from area MT of three male macaque monkeys in two attentional conditions: attention inside the RF and attention outside of the RF. In each trial, a random dot pattern (RDP) moving in the neuron's preferred direction was presented

inside the RF and one or two RDPs with preferred or anti-preferred directions were shown outside the RF.
We used a five-channel Mini-Matrix system to record responses from 301 (monkey H), 101 (monkey C) and 73 (monkey T) neurons. We calculated the power of coupling between the spikes from each isolated neuron and the LFP recorded from the same recording site as the neuron.
We filtered LFPs in 1 Hz steps into frequency bands of 4 Hz width between 1 and 15 Hz. We calculated the spike-LFP coupling power in each frequency band for the time interval between 400 and 1000 ms after stimulus onset. We used the same formula used by (Siegel et al., 2009) to calculate spike-phase coupling (SPC).
We found that across the population of neurons recorded in the three monkeys, the power of SPC for the theta frequency band (3-8 Hz) was decreased by attention ($p < 0.001$, permutation test). The same analysis on each of the monkeys separately showed a significant decrease of SPC for bands of 4-8 Hz (monkey H, $p < 0.05$), 3-7 Hz (monkey C, $p < 0.001$), and 3-7 Hz (monkey T, $p < 0.01$). The size of the effect was 46% across the monkeys.
We conclude that phase coupling between spike occurrences and the large-scale ongoing activity of neuronal populations at theta frequency is decreased in area MT by visual attention. This suggests that attention decreases determinism in spike times across the neuronal population at low frequencies. This can be a possible mechanism for the decrease of interneuronal correlation by attention.

Title: Spike count correlations amongst dorsolateral prefrontal cortical neurons during target selection and allocation of attention

Authors: *T. BACKEN[1,2], S. TREUE[2], J. MARTINEZ-TRUJILLO[1]
[1]Dept. of Physiol., McGill Univ., Montreal, QC, Canada; [2]Cognitive Neurosci. Lab., German Primate Ctr., Goettingen, Germany

Abstract: Visual attention allows us to give the processing of behaviorally relevant stimuli priority over irrelevant ones. An area in the primate brain known to be involved in visual attention is the dorsolateral prefrontal cortex (dlPFC). Neurons in the dlPFC of macaque monkeys can discriminate between relevant and irrelevant stimuli (targets and distractors) through their firing patterns. Interestingly, the degree of suppression of the neurons' response to a distractor is correlated to the animals' performance at filtering behaviorally relevant information. The mechanisms by which dlPFC neurons implement this selection process is unknown. One possibility is that neurons selective for the position of a given attended stimulus interact with other neurons. We investigated such neuronal interactions by measuring spike count correlations between dlPFC neurons in one macaque monkey during a cognitive task: Two visual stimuli were presented on a computer screen on both sides of a central fixation point. The animal had to select the target stimulus based on its color and sustain attention to it in order to indicate a change in one of its features while ignoring similar changes in the other pattern. We implanted a 96-electrode microarray (Utah array) in the monkey's left dlPFC to simultaneously record the activity of many neurons while the animal performed the task. We isolated responses of 74 single units. We divided the neurons into two groups, based on their spatial selectivity. The first group contained the neurons with no preference for the spatial location of the target (n=60), i.e., with similar firing rates for targets on either side of the fixation point. The second group contained those neurons that responded more strongly for targets in the hemifield ipsilateral to the recording site (n=11) (The number of neurons showing a preference of contralateral targets was too small (n=3) to allow a quantitative analysis.). We quantified spike count correlations within each group of neurons. We found that spatially selective neurons showed greater spike count correlations than non-selective neurons. Specifically, they showed an increase of ~80% in mean correlation in their response to an ipsilaterally presented target when compared to the non-selective neurons. When the target was presented on the contralateral hemifield, the spike count correlation increased by ~100% for spatially selective neurons compared to non-selective neurons. Both of these differences in correlation were statistically significant ($p<0.01$). These results suggest that dlPFC neurons that show a preference for the target location interact more strongly during the allocation of attention.

Title: Theta oscillations in the rat medial prefrontal cortex, but not the anterior cingulate or ventral tegmental area, are phase entrained to an attended but not unattended stimulus

Authors: *N. K. TOTAH[1,2,3], B. MOGHADDAM[2]
[1]Physiol. of Cognitive Processes, Max Planck Inst. for Biol. Cybernetics, Tuebingen, Germany; [2]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA; [3]Ctr. for the Neural Basis of Cognition, Pittsburgh, PA

Abstract: The phase entrainment of local field potential (LFP) oscillations to the timing of a stimulus may improve attentional selection by increasing neuronal excitability at the time of stimulus onset. Studies in humans and monkeys have demonstrated phase entrainment to rhythmically presented stimuli, whereas other studies have demonstrated phase entrainment to the onset of non-rhythmic, but attended stimuli. These studies support the idea that the brain may intrinsically generate phase entrainment in expectation of a task-relevant stimulus in order to improve attentional selection. While this idea has been investigated using humans and monkeys as subjects, it has not been studied in the rat. Therefore, we recorded LFP in the rat from brain regions that have been implicated in expectancy and preparatory attention: the medial prefrontal cortex (mPFC), the anterior cingulate cortex (ACC) and the ventral tegmental area (VTA). We employed a well-characterized rodent preparatory attention task that requires the rat to anticipate a brief visual stimulus, which would appear at 1 of 3 randomly selected locations on each trial. Phase entrainment to the stimulus onset was measured by performing Rayleigh's Z test on the distribution of phase angles across all trials, for each subject (n=8 rats for PFC and ACC and n=14 rats for VTA). We assessed phase entrainment between 4 - 50 Hz and only found significant entrainment of ~ 5 Hz oscillations. Across subjects, the excitatory LFP troughs of 5 Hz oscillations were locked to the stimulus onset. Furthermore, this entrainment was only observed in the mPFC, not in the ACC or in the VTA. The 5 Hz entrainment in mPFC was not observed when the rat selected the incorrect stimulus location suggesting a critical linkage between phase entrainment and attention task behavior. At the time of stimulus onset, correct and incorrect trials involved similar motor preparation, motor execution, and reward expectation. Therefore, we suggest that low-frequency oscillations may be a cross-species neurophysiological mechanism for attentional selection of expected stimuli. Selection of an expected stimulus may be implemented by enhancing neuronal excitability at the time of stimulus onset.

Title: Cortical excitation during stop signal task performance in the rhesus macaque.

Authors: *H. P. JEDEMA[1], E. BAEG[2], J. WOOD[3], C. W. BRADBERRY[2,3,4]
[1]Dept Psychiatry, Univ. Pittsburgh, PITTSBURGH, PA; [2]Dept Psychiatry, [3]Dept Neurosci., Univ. Pittsburgh, Pittsburgh, PA; [4]VA Pittsburgh Hlth. Services, Pittsburgh, PA

Abstract: Impairments in inhibitory control are associated with addiction. The stop (signal response) task is used to assess impairments in speed or efficacy in inhibitory control. Imaging and lesion studies have outlined a network of areas involved in response inhibition, but studies examining inhibitory control at the neuronal level have been limited.
To obtain more insight in the neuronal activity in these regions, we made simultaneous recordings in the pre-supplementary motor area (pSMA), SMA, and BA44/45 in a rhesus macaque while she performed a stop task on a touch screen. The appearance of the stop signal was adjusted between trials to maintain successful inhibition in approximately 50% of trials. Go trial accuracy was ~90% and the time required to successfully respond to the stop signal (stop signal response time) was ~247±6msec with a mean go trial response time of ~466±9msec. Latencies are reported from the onset of the go stimulus.
Preliminary analysis indicates that the basal firing rate was 6.1±0.7, 3.5±1.0, and 5.3±1.1Hz in BA45 (n=78), pSMA (n=24), and SMA (n=44), respectively. The neuronal responses were classified in successful go trials (GoCorrect), and successful (StopCorrect) and non-successful stop trials (StopError).
The majority of neurons in BA45 and SMA exhibited activations time-locked to the behavioral response. BA45 and SMA neurons were activated shortly before the release of a hold stimulus was initiated on all trial types (mean release time 112±5msec; activations peaked around 80-90msec for BA45 and SMA).
SMA neurons exhibited a prominent second period of activation on GoCorrect and StopError trials (latency ~420msec). The period of activation on StopCorrect trials was blunted and had a shorter latency to peak (310msec). The second excitation on GoCorrect and StopError trials coincided with the touching of the screen.
BA45 neurons exhibited a second period of activation immediately following the appearance of

the stop signal on both StopCorrect and StopError trials that was absent in GoCorrect trials. The peak of the second excitation in BA45 preceded the peak in the SMA. The second period of activation on StopError trials preceded the commission of the actual error and lasted longer than on StopCorrect trials.
The present data demonstrate prominent activations related to inhibitory control in BA45 neurons and may further our understanding of the mechanisms involved in inhibitory control of prepotent responding.

Abstract: Several experiments have demonstrated the importance of hippocampal theta (4-12 Hz) and gamma rhythms (40-80 Hz), and their mutual coupling, for working memory. However, it is not known whether the reported correlations between these brain rhythms and performance in a memory task relate to attention to the to-be-remembered information or to the maintenance of that information in memory. The present study addressed the role of hippocampal theta-gamma rhythms in a simplified task setting that only required maintained attention to a visible cue.
To control for movement, the known confounding factor for theta, we devised a task in which the rat had to attend to a cue light while continuously pressing a lever for a random duration of 2.5 - 3.0 s. Once the central cue light turned off and a peripheral cue light turned on, the rat had a limited time to make a nose poke into a hole below the peripheral light to obtain a water reward. Under these conditions, theta power did not significantly vary during the entire lever-press period, but increased during the movements associated with the lever release and turning around. In contrast, increased gamma-power during the lever press indicated an erroneous premature

release of the lever.

Title: Bidirectional optogenetic control of cortical acetylcholine signaling demonstrates vital contributions to attentional performance

Authors: *H. GRITTON[1], C. S. MALLORY[2], V. L. HETRICK[1], J. D. BERKE[1], M. SARTER[1]
[1]Psychology and Neurosci. Program, [2]Psychology, Univ. of Michigan, ANN ARBOR, MI

Abstract: Photostimulation of cholinergic neurons expressing channelrhodopsin-2 (ChR2) produces transient increases in acetylcholine release that resemble those seen during cue detection in attention task-performing animals (Gritton et al., 2010). Cholinergic lesions of the prefrontal cortex also produce cue detection deficits in attentional tasks (Parikh et al., 2007). Here we use optogenetics to determine if cholinergic signaling plays a causal role in signal detection and if inhibition during cue presentation reproduces the deficits noted in animals with cholinergic lesions. To achieve specificity of expression, viruses for doublefloxed channelrhodopsin (ChR2) or halorhodopsin (eNpHR3.0) were infused into the basal forebrain (SI/nbM) of ChAT-Cre mice. Animals were later implanted with optic fibers (200µm) into the basal forebrain and the medial prefrontal cortex, thereby allowing illumination of either cholinergic cell bodies or select terminals for comparisons during task performance. We found that combining optogenetic cholinergic stimulation with cue presentation augmented cue detection, and cholinergic stimulation without cue presentation produced more false alarms. A comparison between stimulation sites revealed that photo-activation of cholinergic prefrontal

terminals alone was as effective as somatic stimulation in producing this effect and scaled with light intensity and expression levels. Importantly, increases in false detections were not observed in non-infusion controls. Conversely, inhibition of cholinergic cell bodies beginning before cue presentation and extending through the cue period significantly attenuated cue detection. Unlike the outcomes noted for ChR2, inactivation of prefrontal terminal fields did not impair cue detection, suggesting that inhibition across larger cortical fields is necessary to mimic the effects of cholinergic lesions. These results directly demonstrate the key contribution of timed cholinergic signaling to the detection of unpredictable cues in attentionally demanding contexts and provide insights into the impact of poorly orchestrated cholinergic signaling during cognitive performance.

Title: Relationship between spike-synchrony & 'noise' correlation mechanisms in animals performing feature selective attention tasks

Authors: *M. GOMEZ-RAMIREZ, N. TRZCINSKI, S. S. HSIAO
The Zanvyl Krieger Mind / Brain Inst., Johns Hopkins Univ., BALTIMORE, MD

Abstract: The prevalent model of feature selection indicates that attention increases a neuron's response when the attended-feature matches the feature-preference of that neuron. This mechanism has been described as the feature-gain similarity model of attention (FGSM), and it has been primarily observed in the firing-rate (FR) of visual cortical neurons. However, attention can also influence activity across neural ensembles by either increasing the spike-synchrony (SS) or reducing the interneuronal correlated noise (ICN) across neural pairs. Yet, whether these mechanisms play a role in sensory selection and how they interact with each other is unknown.

Here, we examined whether attention modulates the SS and/or ICN of neural pairs according to the FGSM, and whether they hold any bearings to perception by examining their relationship to behavior. Finally, we characterized the links between SS and ICN to ascertain whether they share common sources of top-down attention. To answer these questions, simultaneous recordings were made from multiple neurons in secondary somatosensory cortex (SII) while animals' performed three different selective attention tasks. On every trial, a visual cue instructed the animal to engage in a tactile-orientation, a tactile-frequency, or a visual task that was unrelated to the tactile stimulus. Following 1000 ms the cue onset, a vibrating-oriented bar was indented to the animals' hand, which was followed by a visual response cue consisting of a pair of circles. The animal made a saccade to the correct circle depending on the task. If the animal performed the visual task, it ignored the tactile stimulus and made a saccade to the circle with higher brightness. The data showed that attention increased the SS across neural-selective pairs when it matched the feature-preference of the neurons. This effect was also replicated in the FR of individual neurons, but with lower prevalence across the population. However, attention did not affect the ICN across neural pairs in a feature specific manner. Instead, the ICN of the entire cell population decreased when attention was deployed to touch compared to vision. Importantly, the data also revealed a relationship between behavior and SS, whereby greater SS was associated with higher performance during the tactile task, whereas the opposite was observed when attention was deployed to vision. Finally, the data revealed an inverse relationship between ICN and SS. Our findings are in agreement with the FGSM, but suggest that SS and ICN are affected by different sources of top-down attentional signals. Finally, these data highlight the importance of studying perceptual mechanisms at the population level.

Title: Interareal gamma-band synchronization in primate ventral visual pathway underlies signal routing during selective attention

Authors: *I. GROTHE[1,2], S. D. NEITZEL[1,2], D. ROTERMUND[2,3], S. MANDON[1,2], M. LINKE[2,3], U. A. ERNST[2,3], K. R. PAWELZIK[2,3], A. K. KREITER[1,2]

Abstract: When two stimuli are present in a visual receptive field (RF), the neuron can respond as if it only would receive the signal input from the attended stimulus, even if this stimulus is not preferred by the neuron. It has been proposed that selective gamma-band synchronization between downstream neurons and the subset of their inputs carrying the relevant signals may directly lead to such routing of the attended stimulus signals. However, a direct link between selective interareal synchronization and signal transfer remains to be demonstrated.
With this goal, we trained two macaque monkeys to attend to one of two sequences of morphing shapes and to respond to the reoccurrence of the initial shape in the cued sequence. While the monkeys were engaged in this spatial attention task, we recorded local field potentials (LFPs) from areas V1 and V4 simultaneously. The shapes were placed into two non-overlapping V1 RFs, encompassed by a V4 RF. Every 10ms, the luminance of the filled shapes was randomly changed, independently for each stimulus. We computed spectral coherence between stimulus luminance and the LFPs as a measure of the effective contribution (EC) of each stimulus to the neuronal activity in each area. The EC serves as a direct and unambiguous quantification of coupling in terms of linear causation.
We observed strong gamma-band LFP synchronization between the V4 population and the V1 input subpopulation representing the attended stimulus. As expected, this was accompanied by a high EC of the attended stimulus to the V4 LFP. Simultaneously, the EC of the non-attended stimulus was several times lower and also gamma-band synchrony between the same V4 population and the V1 input subpopulation representing the non-attended stimulus was only weak. A switch in attentional locus was accompanied by a switch in the interareal gamma-band synchronization pattern and a reversal of the stimuli's ECs to the V4 LFP. Importantly, this was not due to attentional modulation of the EC in the V1 LFPs. Lastly, the strength of the selective gamma-band synchrony and EC were found to be highly correlated. These observations were reproduced in a minimal model that uses interareal gamma-band synchronization as a selective gating mechanism, demonstrating that selective interareal gamma-band synchrony can indeed implement the observed selective information routing.
Altogether, our study shows convincingly that interareal gamma-band synchrony is directly related to the selective routing of attended stimulus signals through the visual cortex and thus supports the hypothesis that oscillatory synchrony between areas underlies the routing of information throughout neuronal processing systems.

Title: Long-range frontal-parietal gamma coherence is associated with sustained attention in rats

Authors: *M. C. WIEST, L. HERZOG, K. SALEHI
Neurosci., Wellesley Col., Wellesley, MA

Abstract: To test whether long-range neural coherence supports attention, local field potentials (LFPs) were recorded in frontal and parietal cortex while rats performed an auditory signal detection task. We observed significantly more frontal-parietal gamma coherence (30-80 Hz) before the signal on hit trials than miss trials. Gradual changes in behavioral responding over the course of a session failed to account for the hit-miss coherence difference. These results support that frontal-parietal gamma coherence underlies sustained attention to an external stimulus, and the rat as a model of primate attentional mechanisms.

Title: Switches of selective neuronal synchronization patterns segregate attentional and decision making processes in macaque prefrontal cortex

Authors: *S. WESTENDORFF[1], D. KAPING[1], M. VINCK[2], S. EVERLING[3], T. WOMELSDORF[1]

Abstract: Multiple brain areas within the primate prefrontal cortex are implicated to subserve the control of attention as well as to guide decision making (Rushworth et al., 2011, Neuron). Covert attentional selection of an object or memory typically precedes the overt choice of the so selected representation. It has remained unresolved, however, how neurons ensuring focused attention, and neurons integrating decision variables to arrive at a choice are interacting during goal directed behavior. Previous studies suggest that the local integration and temporal coordination of distinct functions is subserved by rhythmic synchronization among the constituent neurons. We therefore set out to test whether selective synchronization patterns of single neurons across medial and lateral prefrontal cortex (PFC) subdivisions allow to identify the integration or segregation of attentional or choice related processes.
We recorded from >800 neurons in macaque monkeys trained on a selective attention task and quantified spike to LFP synchronization patterns during two distinct processing states: (1) A selective “attentional state” in which monkeys sustained focused attention towards one of two peripheral stimuli, and (2) during a “decision point” requiring a 2-discrimination forced choice about a transient clockwise/counterclockwise rotation of the attended target stimulus.
We found that a large proportion of single neurons reliably phase synchronized their spiking responses to the LFP across a broad range of frequencies during attentional states (~38%) and during the decision period (~19%).
During both, attention and decision epochs, about 25% of neurons with significant phase locking synchronized in the classical gamma range (40-70). The percentage of neurons synchronizing to theta/alpha and beta ranged from 10-15% in both epochs. Notably, the populations of neurons synchronizing at gamma / beta in both epochs was largely segregated. Common rhythmic modulation across epochs was restricted to neurons with theta/alpha synchronization.
These results reveal that large subsets of PFC neurons show statistically reliable synchronization and that transitioning between focused attentional and choice processes is evident in switches of synchronization. Apart from segregation of processing by switches of synchronization, the temporal integration of attentional and choice processes may be subserved by neurons with a common theta rhythmic firing.

Title: Attentional deficits in mouse offspring born small or large for gestational age are due to a double dissociation between distractibility and decreased motivation.

Authors: *T. M. REYES, N. M. GRISSOM, J. DESILETS
Pharmacol., Univ. Pennsylvania, Sch. of Med., PHILADELPHIA, PA

Abstract: Overly small or large gestational size (SGA and LGA, respectively) and maternal obesity are frequently reported to increase in offspring the risk of mental disorders regulating cognition and attention, particularly Attention Deficit/Hyperactivity Disorder (ADHD), and in the case of maternal obesity, increase the risk of autism and cognitive delay. However, it is difficult in human work to disentangle gestational size and development from other variables that may promote offspring psychological dysfunction. Using mouse models of SGA (maternal low-protein diet) and and LGA/maternal obesity (maternal high-fat diet), we have examined adult male C57xDBA F1 offspring in an operant behavioral battery to determine if gestational nutrition plays a direct role in behavior and cognition related to reward. We first examined animals on a version of Pavlovian Conditioned Approach (PCA) developed for mice, as propensity to form Pavlovian approach associations with a “sign” that predicts reward has been associated with impulsivity and hyperactivity in rats. SGA offspring have a greater tendency to approach the sign relative to control and LGA offspring, suggesting SGA are particularly susceptible to distraction by environmental stimuli. After PCA, animals were trained on fixed ratio (FR1) nose poking followed by progressive ratio (PR) testing. LGA offspring were slightly delayed at learning FR1 over the first 5 days relative to SGA and control offspring, but performed equivalently after additional training. In PR, LGA offspring terminated responding slightly but significantly earlier than control and SGA, indicating deficient motivation to seek rewards as a specific deficit of LGA. Animals were then trained on a series of increasingly challenging 5-choice serial reaction tasks (5C) to assess their attentional abilities. Analysis early in 5C training indicates that both SGA and LGA offspring have similar performance deficits in an easy version of the 5C task, with fewer correct trials and fewer trials overall, driven by trends towards increased numbers of premature and omitted trials in both groups. We are continuing with 5C training, with animals progressing towards a 5-choice continuous performance test to overtly assess ability to inhibit prepotent responding during no-go trials. Overall, current data

collected indicate that both maternal overnutrition and undernutrition promote increased risk of inattention, supporting the human observations, but do so via dissociable mechanisms related to innate distractibility in SGA offspring versus decreased motivation to perform in LGA offspring.

Title: Monkey math: Linear symbolic addition by macaques.

Authors: *W. W. PETTINE[1], B. MOORE[2], M. LIVINGSTONE[1]
[1]Neurobio., Harvard Med. Sch., Boston, MA; [2]Neurobio., Vanderbilt Univ., Nashville, TN

Abstract: Three macaques were given an addition task using dots and then the same task with a learned symbol set. They had previously been trained on a pairwise comparison task to associate 26 distinct symbols with 0 to 25 drops of fluid reward. For the addition task, the macaques chose between a sum of value 0 to 25 represented by two addend symbols vertically separated on one side of the screen, and a single symbol representing a value between 0 and 25 on the other side of the screen. They were rewarded with the corresponding magnitude of whichever side they chose. After a period of several months on this addition task, their choice behavior indicated that they were combining the two addends to obtain an approximate value equal to their sum. To eliminate the possibility that they had memorized the value of all 351 possible sum combinations, we taught the monkeys a second symbol set with the same pairwise comparison task used for the first symbol set. Their performance, even from the first few days, on the task using the novel symbol set indicated that they had successfully generalized the addition task from the first symbol set to the second.
We then asked whether their valuation of the sum was consistent with a logarithmic or linear underlying scale for the symbols. If the underlying scale was logarithmic, their valuation of the sum would increase with the product of the addends. A linear underlying scale would result in the addends linearly combining to form the subjective sum. Their addition behavior was best

accounted for by a linear scale and showed no evidence of an underlying logarithmic scale.

Title: Restaurant row: Identifying revealed preferences in the rat

Authors: *A. D. REDISH[1], A. P. STEINER[2]
[1]Dept. Neurosci, Univ. Minnesota, MINNEAPOLIS, ; [2]Grad. Program in Neurosci., Univ. Minnesota, MINNEAPOLIS, MN

Abstract: Valuation of reward is subjective and depends on personal preferences. How long one is willing to wait for a reward depends on the subjective valuation of that reward and the set of other options available. In order to directly measure the subjective valuation economically, one needs a task in which an animal can reveal its preferences.
Rats were trained on a new task (Restaurant Row), in which they had to make skip/stay decisions at a sequence of choices. The maze consisted of an octagonal loop with four spokes. At the end of each spoke, a feeder provided a unique flavor (white/non-flavored, banana, fruit, and chocolate). The rat ran clockwise around the loop; zones were only activated in sequence. As the rat passed each spoke, a tone sounded indicating the delay it would have to wait before receiving food. The rat could either stay on the spoke and wait out the delay (as the tone decreased in

pitch, counting down the remaining seconds until food delivery) or leave the zone and proceed on to the next spoke. Delays ranged from 0 to 45 sec and were generated pseudo-randomly, so the rat did not know what the delay of the next option would be. By examining which delays the rat would wait out and which it would skip, we were able to determine the flavor preferences for each rat. Each rat displayed a different array of preferences, but preferences remained generally consistent within rat. On occasions where the rat decided not to stay, it left after only a couple of seconds, independent of the delay, indicating that the decision was made based on an unwillingness to wait. Changing the size of the reward (from 1 to 3 pellets) increased the delay the rat was willing to wait, suggesting an economic valuation process.
Rats occasionally paused at the entry to each zone, and oriented towards the two options (down the spoke or around the loop), a behavior known as vicarious trial and error (VTE). VTE occurred maximally at the threshold between short delays (stay) and long delays (skip), even though the threshold differed between options. When rats encountered a long delay to a less-preferred food after skipping a long delay to a more-preferred food, they occasionally looked backward towards the previous spoke, but did not actually proceed backwards towards the previous spoke.
Preliminary neural data in OFC identified many neurons that showed responses for specific rewards, in agreement with prior research. Data from vStr also demonstrated reward responsive activity as well as showing increased firing rates prior to feeder arm entry. These results illustrate revealed preferences in rats and offer the potential to describe the time course of interaction between OFC and ventral striatum during decision making.

Title: Vicarious trial and error (VTE) behaviors on a spatial delay-discounting task

Authors: *A. PAPALE[1], P. S. REGIER[2], J. J. STOTT[2], N. J. POWELL[2], A. D. REDISH[3]
[1]Neurosci., Grad. Program in Neurosci., MINNEAPOLIS, ; [2]Neurosci., Grad. Program in Neurosci., MINNEAPOLIS, MN; [3]Dept Neurosci., Univ. of Minnesota, MINNEAPOLIS, MN

Abstract: Delay-discounting experiments measure choices made between taking a smaller reward sooner versus waiting for a larger one later.Discounting behavior can be inferred from an adjusting delay procedure in which the delay to the larger reward is increased when the larger reward is chosen and decreased when the smaller reward is chosen. The adjusting delay procedure is designed to allow the animal to titrate the delay until both options are preferred equally (the indifference point).
We present a spatial T-maze version of the adjusting delay-discounting task. Because rats naturally prefer to alternate between options on a T-maze (spontaneous spatial alternation), the spatial delay-discounting task does not need forced choice trials to ensure that rats try both options. Delay was increased or decreased by 1s on each lap depending on the choice of the rat on that lap; both sides had a minimum delay of 1s and no maximum delay. Each session, rats investigated the options for a given day, adjusted the delay to a preferred indifference point, and then alternated at that indifference point.
11 rats were trained to run 100 laps per session at a reward ratio of 3 to 1. The initial delay for the larger reward began each day at a pseudo-randomly selected delay from 1s to 30s . Rats reliably titrated the adjusting delay to approximately 6-8 seconds.
4 rats were trained to run 100 laps per sessions for larger rewards of 1 to 5 pellets. The size of the larger reward remained constant on each day but changed from day to day. An additional rat was not given a lap constraint but was allowed to run each session until he received 200 pellets (9g). All 5 rats reliably titrated to higher delays for larger rewards, with delay by reward size showing significant linear slope, consistent with hyperbolic discounting.
Rats sometimes pause and orient toward potential options before making a choice, a process termed vicarious trial and error (VTE). VTE has been hypothesized to reflect perceptual exploration of uncertain alternatives, mediation of conflict through conditioned orienting, discrimination among fixed-value alternatives, and activation of a deliberative, search-based decision process. On the spatial delay-discounting task, VTE primarily occurred during adjustment laps. VTE continued to occur long after the alternatives were known (rats reliably titrated to the indifference point, indicating knowledge of task structure). VTE did not occur during the final alternation phase of behavior (during spatial alternation when the discounted values were equal). VTE was most likely to occur when an adjustment lap interrupted a series of alternation laps, suggesting a role in flexible decision-making processes.

Title: Vicarious trial and error (VTE) behaviors on a task that puts place and response strategies in conflict

Authors: *B. SCHMIDT[1], A. E. PAPALE[2], E. J. MARKUS[4], A. D. REDISH[3]
[1]Neurosci., Univ. Minnesota, Minneapolis, ; [2]Grad. Program in Neurosci., [3]Dept Neurosci., Univ. Minnesota, Minneapolis, MN; [4]Dept. of Psychology, Univ. of Connecticut, Storrs, CT

Abstract: Spatial tasks can be accomplished by multiple decision-making strategies, using different information-processing computations. A well-studied dichotomy in these decision-making strategies on spatial tasks compares “place” and “response” strategies. Place strategies tend to depend on hippocampal integrity, while response strategies tend to depend on dorsolateral striatal integrity. Place strategies are needed when rats approach a single location from multiple starting positions, while response strategies are needed when rats need to take the same action from multiple starting positions.

When rats reach decision points, they sometimes pause and orient towards their routes, a process termed vicarious trial and error (VTE). VTE co-occurs with neurophysiological information processing in structures associated with place strategies, including sweeps of representation ahead of the animal in hippocampus and transient representations of reward in ventral striatum and orbitofrontal cortex. However, these effects are not present in dorsolateral striatum.

In order to examine the relationship between VTE and the place/response strategy dichotomy, rats were trained to continuously switch between place (“go east”) and motor-response (“turn right”) navigation strategies on a modified plus maze for food reward. Place trials were cued by the presence of a flashing light. (The light did not indicate which arm was correct, only that the trial was a place-trial.) The configuration of the maze allowed for place and response strategies to work competitively (each strategy indicating a different goal arm) or cooperatively (both strategies indicating the same goal arm).

VTE was quantitatively measured as the integrated absolute angular velocity across the pass through the central choice-point. VTE was preferentially exhibited in rats when cued to utilize a place strategy over a response strategy. VTE was preferentially exhibited on incorrect trials and on the more difficult trials that exhibited greater competition between the navigational systems. Interestingly, when individual trial types were examined, the use of place strategies was found to

exert a greater modulating factor than competition between the navigation systems. Upon further examination we noted that VTE was seen on trials when rats were cued to use the response strategy but incorrectly utilized the place strategy, further supporting a preferential role of VTE in place strategy performance.

Title: Implications of the multiple-decision making systems theory for Contingency Management

Authors: *P. REGIER[1], A. D. REDISH[2]
[1]Univ. of Minnesota, Minneapolis, ; [2]Dept Neurosci., Univ. of Minnesota, Minneapolis, MN

Abstract: Contingency Management (CM) consists of rewarding a subject for behavioral modification such as abstinence from drug-use (Petry 2011). In voucher-based CM, subjects earn points that are worth money for each proof of abstinence. These points accumulate towards the purchase of specific merchandise. Prize-based CM provides a chance to win a prize for each proof of abstinence. Clinical studies of Contingency Management have shown consistent and significant reductions of drug use in addicts for a number of different addictive drugs.
Although this treatment method has its basis in alternative reinforcement theory, providing monetary rewards contingent upon the proof of abstinence and extra incentive for continuous abstinence, the size of rewards is small compared to the elasticity of drug-use. We hypothesize that CM does not work by alternative reinforcement alone.
Abstinence is an abstract concept that typically includes delayed rewards while drug use includes concrete immediate rewards. Because temporally-distant rewards are discounted relative to more proximal rewards, one potential source of CM's success is that it provides concrete rewards for abstinence. Recent experimental data suggest that making a reward more concrete decreases the amount it is discounted for a given temporal delay (Peters and Buchel 2010). Recent modeling work suggests that this may occur because concrete rewards are easier for search processes to find (Kurth-Nelson, Bickel, Redish 2012).
The Multiple Decision-Making Systems theory (van der Meer, Kurth-Nelson, Redish 2012)

suggests that CM may also encourage the use of one decision-making system over another. An addict's desire to abstain can be undermined by Pavlovian action-selection systems which preferentially approach (and use) concrete, immediately available options that have been learned to have high Pavlovian value. Similarly, an addict's desire to abstain can be undermined by Habitual action-selection systems, which respond to learned cues. We hypothesize that a concrete choice between using a drug vs. receiving a voucher or prize for abstinence engages the Deliberation system. By providing concrete actions that Deliberative search systems can find allows the Deliberative search to outcompete other components and suggests that deliberative system training (such as through working memory training (Bickel et al 2011) may increase CM's success even further.

Title: Delay discounting of oral morphine and sweetened juice rewards in dependent and non-dependent rats.

Authors: *C. HARVEY-LEWIS, J. PERDRIZET, K. B. J. FRANKLIN
Psychology, McGill Univ., Quebec, QC, Canada

Abstract: Opiate dependent individuals are frequently reported to be more impulsive than non-dependent controls. Opiate dependent rats exhibit similar tendencies; we previously reported that inducing morphine dependence resulted in a transient increase in impulsive choice of sucrose rewards. Interestingly, opiate dependent humans are more impulsive towards opiate rewards than monetary rewards. This indicates that when drugs are involved, dependent individuals make even more impulsive decisions than usual. To test this finding in rats, we first validated the use of a cocktail of 10% grapefruit juice, 20% sucrose and 1mg/mL morphine as an oral morphine reward. In a two-lever operant choice paradigm rats preferred the morphine cocktail over a similar drug-free solution (10% grapefruit juice, 20% sucrose solution) but preferentially selected the drug-free solution over a cocktail where quinine was substituted for morphine. Rats consumed sufficient morphine to induce analgesia. We examined impulsive choice of morphine and drug-free cocktails in dependent and non-dependent rats using a delay discounting (DD)

paradigm. Rats were trained to press one of 2 levers for the drug-free solution. Pressing one lever yielded a small immediate reward (50µl of solution) and the other yielded a larger delayed reward (150µl of solution). DD sessions consisted of 5 blocks of 14 forced trials. On the first 4 trials of each block rats were forced to sample each reward twice. On the following 10 trials rats could choose either lever. Length of the delay was systematically increased (0s, 5s, 9s, 16s, 30s) between successive blocks within session. A DD curve was determined by plotting mean proportion choice for the larger reward against delay. Once baseline DD curves were determined, rats were randomly assigned to either a dependent group that received a nightly 30mg/kg subcutaneous dose of morphine, or a non-dependent group that received a nightly saline injection. Test DD curves were then determined 22hr after nightly injections. In each group, half of the rats received morphine cocktail as reward for test DD and half received the drug-free solution. When compared to baseline and the non-dependent group, dependent rats showed a significantly decreased preference for the large reward at 5s, 9s, 16s delays. However, both reward types were discounted similarly. These results show that morphine dependence can cause a general increase in impulsivity that is not enhanced by drug reward.

Title: Outcome expectancy signals in macaque OFC in a curiosity task

Authors: M. MANCARELLA[1], T. C. BLANCHARD[1], *B. Y. HAYDEN[2]
[1]Brain and Cognitive Sci., [2]Univ. of Rochester, Rochester, NY

Abstract: A recent theory holds that the chief function of the OFC (especially the lateral portion, sometimes known as lOFC) is to signal outcome expectancies - rewards predicted from specific stimuli (Schoenbaum, Roesch, Stalnaker, and Takahashi, 2009). This theory holds that OFC signals serve to predict the rewards that would be obtained following the choice of a given option and also track the reward obtained following the choice. This primitive reward signal is distinct from other reward signals, especially the reward prediction error, which signals the difference in reward (cued or obtained) and prediction. In order to test the idea that OFC signals outcome expectancies, we recorded responses in a task that offered a choice between two 50/50 gambles

with delayed (2.25 sec) resolutions. One gamble offered information about the upcoming reward immediately while the other offered no such information (Bromberg-Martin and Hikosaka, 2009). Extending earlier work by Bromberg-Martin and colleagues, we found that monkeys are highly information-seeking, preferring earlier resolution to delayed resolution by approximately 20% of average reward size. We recorded single unit activity in area 13m, a centrally located region in the lateral network of the OFC (Ongur and Price, 2000). We found that neural activity signalled rewards expected following valid reward-predicting cues, but not during matched invalid cues. We also found that neural activity signalled reward obtained following the resolution of the gamble and did not depend strongly on expectation. These results endorse the outcome expectancy hypothesis, and thus help carve out a unique role for OFC in reward-based cognition.

Title: How to get there?: Action sequence strategies for solving navigation problems

Authors: *A. R. FONSECA, M. MURAKAMI, Z. F. MAINEN
Champalimaud Neurosci. Programme, Lisboa, Portugal

Abstract: Navigation is a fundamental behavioral problem solved by animals. Nevertheless, its neural bases are poorly understood. Computationally, defining the path to a goal requires integrating information about current self-location and heading with information about goal location. Several kinds of neural representations of self-location and heading have been described in the rodent brain, including place cells, head direction cells and grid cells. In comparison, much less is known about how goals or goal paths are represented neurally. Ultimately, this navigational information must be used to select which action sequence will be executed to reach the goal. To explore these problems, we developed a behavioral paradigm where a rat has to solve a navigation problem by selecting which action sequence will lead to a specific goal on a trial-by-trial basis. We designed a squared grid maze with 9 water ports and

1.5m side. In each trial, water availability was assigned to a given port location and cued by a constant light co-localized with the assigned port. The light was on until the rat poked in breaking a light beam which simultaneously turned the light off and activated the release of water followed by a 2 s inter-trial interval. Our training strategy was to offer the rat the possibility of harvesting reward in several cued locations and then decrease slowly this number until rat could only get water from one port. After 5 days of training, rats performed more than 250 correct trials in one hour session. Because we could control indirectly the current position of the rat and the goal, manipulations of navigational behavior were very simple to introduce. For instance, we could force the rat to change its action sequence plan by changing the goal port after the animal had started its action execution. This is equivalent to introduce a barrier in a familiar path.Our aim is to gain a better understanding about the neural representations underlying the use of navigational information to select motor sequences and this task due to characteristics both as a navigational paradigm and an action sequence paradigm seems to us as good behavioral framework to look for these neural correlates.

Title: Interplay of confidence and value in the transformation of olfaction to action

Authors: *G. M. COSTA[1,2], Z. F. MAINEN[1]
[1]Champalimaud Neurosci. Programme, Lisboa, Portugal; [2]Ctr. For Neurosci. and Cell Biol., Coimbra, Portugal, Coimbra, Portugal

Abstract: Difficult decisions can occur because stimuli are hard to perceive or because the rules of what should be done given a certain stimulus are uncertain to the decision maker. We would like to understand how this second form of uncertainty is represented by the brain and may be assessed and used for adaptive behavior. In addition, we are interested in the relationship between uncertainty and value in such decisions. To study these issues we developed a perceptual decision task in which rats are trained to perform a binary categorization of an odor

mixture and report their decision confidence by reward waiting time (Kepecs at al., 2008) in a post-decision wager paradigm. From trial-to-trial odour mixtures were presented at one of three different mixture ratios. The distance of the mixture ratio from 50/50 determined the uncertainty or difficulty. Rats indicated their choice by moving from the odor port to a left or the right choice port. For correct trials, a reward was delivered after a random exponentially distributed delay (2 s mean). In error trials and catch trials (15% of correct trials) no reward was delivered and rats had to make a decision when to exit the choice port and reinitiate a new trial. Decision confidence was indexed by waiting time in those trials. In order to dissociate neuronal representations of confidence and value we introduced an additional manipulation of reward magnitude: in alternating blocks of trials one of the two choice sides was rewarded with 3 times more water than the opposite side. As expected, this reward manipulation biased the choice function of the animals towards the more rewarded side. In contrast, the confidence report was unaltered by the value manipulation: leaving times for the high and low reward ports were not different. We are currently investigating the neural substrates of this behavior. Recordings from the anterior piriform cortex (aPCx), together with previous behavioral results, suggest that rats have a high fidelity representation of the odor cue, but that variability is introduced downstream of this sensory representation. We hypothesize that the olfactory tubercle (OT, an olfactory striatum) is the site where odor representations are linked to action values and therefore the site at which uncertainty in the olfactory categorization task originates. To test this we are conducting electrophysiological recordings from multiple single units in aPCx and OT while rats (n=6) performed the categorization task and we have been exploring this dataset.

Title: Coordination in rats: The use of game theory to study the proximal mechanisms of cooperation.

Authors: *S. M. RENNIE, M. MOITA
Champalimaud Fndn., Lisbon, Portugal

Abstract: Animals must survive in an ambiguous world governed by shifting probability landscapes where the likelihood of available outcomes is reciprocally intertwined with their own behavioural choices. This is most
evident in social interactions in which the outcome of one's decision can be influenced by the decisions of other animals. An automated double T-Maze for testing behaviour in 2x2 social dilemma games has been developed to examine how rats make adaptive behavioural choices during social interactions. We have employed a simple coordination task with pellet rewards corresponding to a Stag Hunt (SH) game that are both discernible and desirable to rodents. By fixing a pseudo random strategy for one rat (stooge) and observing the choice of a freely behaving rat (agent) it was found that rats rapidly engage in coordination. This suggests that rats are able to understand the economic terms of the SH game and optimize their behaviour accordingly.We will then observe the behaviour of two agents in a SH game. Importantly in this game there are two Nash equilibria: mutual cooperation which yields the highest reward but entails the highest risk and mutual defection which yields a constant intermediate reward. In this case rats must choose whether to risk cooperating first, defecting, or following the other. We propose that choosing to cooperate first may be used as a measure of 'trust'.

Title: Behavioral study of fictive outcome in a monkey using a value-based binary choice task

Authors: *H. TAKAHASHI[1], S. FUNAHASHI[2]
[1]Grad. Sch. of Human and Envrn. Studies, [2]Kokoro Res. Ctr., Kyoto Univ., Kyoto, Japan

Abstract: Fictive outcome refers to the outcome which is not directly experienced. We refer to both actual outcome, outcome of our own past choice, and fictive outcome to make a choice. Although many studies have focused on the actual outcome, much less is known about the fictive outcome and its contribution to choice. To examine how the fictive outcome modulates animal's choice, we developed the following value-based binary choice task. Two visual cues which were associated with different reward probability and amount were presented and a monkey freely chose one of them. Once the monkey chose a cue, outcomes (either hit or miss) for both chosen

and unchosen cues were presented. The outcome of the chosen cue represented whether the monkey could receive reward. The outcome of the unchosen cue represented whether the monkey would receive reward if the monkey chose the unchosen cue. Therefore, regardless of the outcome, the unchosen outcome did not affect giving of reward.
We examined whether the outcome of the unchosen cue influence monkey's choice behavior. We predicted that the monkey would be more likely to change his choice in the next trial under the condition in which the outcome of the unchosen cue was hit and the outcome of the chosen cue was miss, compared to the condition in which the outcomes of both the chosen cue and the unchosen cues were miss. However the monkey did not show such a choice pattern. We also examined how the outcome of the unchosen cue affected the length of trial start time (an interval between presentation of a fixation point and the time when the monkey starts gazing at it). Trial start time is considered to reflect animal's motivational state, such that it tends to be longer as animal's motivation decreases. We predicted that the trial start time would be longer if the outcome of the chosen cue was miss. Furthermore, the trial start time would be longer under the condition in which the outcomes of both the chosen and unchosen cues were miss compared to the condition in which the outcomes of the unchosen cue was hit.. However, significant difference in the trial start time was not observed between these conditions. Thus, the fictive outcome tends not to affect the monkey's choice, if the monkey has learned association learning between the cue and its reward probability/amount. To examine the effect of the fictive outcome on animal's choice, it is appropriate to analyze choice behavior during the process of the association learning.

Title: Dissociable effects of amphetamine on stopping and performance monitoring for rats in the countermanding task

Authors: *J. BEUK[1], R. J. BENINGER[2], M. PARÉ[3]
[1]Dept. of Physiol., [2]Psychology, [3]Physiol., Queen's Univ., Kingston, ON, Canada

Abstract: The countermanding paradigm has been developed to examine a subject's ability to withhold responses to a go stimulus when a stop signal is presented occasionally, as a measure of executive function (Logan & Cowan, 1984). Deficits in countermanding task stopping, which are indicative of impairments in behavioural inhibition, have been ameliorated with amphetamine treatment in humans and rats (de Wit et al 2002, Eagle et al 2003, Feola et al 2000). The countermanding task provides a separate measure of executive function through the analysis of performance monitoring by tracking trial-to-trial changes in task performance produced by differences in trial and performance history. The aim of our experiment was to examine performance monitoring and changes produced by amphetamine treatment in rats. Male Wistar rats were trained to respond to a visual stimulus (go signal) by pressing a lever below an illuminated light for food reward, but to countermand the lever press (25% of trials) subsequent to an auditory tone (stop signal) presented after a variable delay. Rats displayed go response time (goRT) speeding after consecutive go trials and goRT slowing on trials following errors. Amphetamine administration improved countermanding task performance by speeding goRTs and producing baseline-dependant alterations in stop signal response time. Preliminary results suggest that amphetamine administration impaired performance monitoring by decreasing goRT speeding and post-error slowing. Together, these results suggest that amphetamine administration in rats improves stopping, but may impair performance monitoring. These results may reveal dissociable measures of executive function for rats in the countermanding task. (Funded by NSERC)

Title: Behaviour and decision making: Neuroeconomics, corruption in higher education and shock waves

Authors: *M. ORKODASHVILI
Vanderbilt Univ., Tbilisi, Georgia

Abstract: The paper discusses the issue of corruption in higher education through neurocognitive prism. Mental causation, human behavior, cognitive processes taking place in the brain, risk-taking endeavors, all lend to *neurocognitive* field of research. The paper refers to the

examples of institutional and departmental mergers in higher education sphere that are usually accompanied by staff dismissals and shock effects that spread shock waves.
Departmental and institutional mergers at Tbilisi State University, Ilia State University and Tbilisi Free University present further instances that are useful for *neuroeconomic* and *neurocognitive* analysis of profit-maximization considerations, coercive pressures coming from governmental agents and brain's manipulative capacities that allowed for quality evaluation distortions in all those instances.
By explicitly modeling physiological properties, it is possible to provide *foundations for some elements of preferences traditionally considered exogenous*, such as risk aversion, ambiguity aversion, or time-preference rates. Choices involving risk, uncertainty, or time delays may require complex trade-offs. Measures of brain activity allow us to determine if the evaluation process is centralized or if different brain systems compete to influence the final decision. *Neuroeconomic* theory proposes to model the actual brain organization, determine the behavior that emerges from it, and evaluate which theory fits best.
Research uses neurobiological evidence to model inter-temporal choices as the result of a conflict between two brain systems, one interested in immediate gratification and one that can form a mental representation of future rewards.
The following important points have been singled out in the paper: • The amount of information available • Risk aversion strategies - increasing confidence level • How choices are made in the brain of an agent During staff and faculty dismissals at Tbilisi State University the linguistic means of communication, expressed through ambiguous syntactic structures, metaphors with dubious meanings and multiple neurolinguistic techniques engendered and deepened cognitive perceptions and feelings of insecurity, instability and intimidation among the dismissed individuals. The result was the 'production' of two main types of actors: those who were shocked, confused insulted, and intimidated, and those who got grips with the ongoing developments and joined in the manipulative and coercive circles of individuals who used the created shock waves, ambiguity and confusion to their advantage.1

Title: Impulsive choice is driven by perception of time in male, but not female, adolescent rats

Authors: *J. MCCLURE[1], F. JACKSON[2], H. N. RICHARDSON[3]
[1]Univ. of Massachusetts Amherst, South Hadley, MA; [2]Univ. of Massachusetts Amherst, Amherst, MA; [3]Univ. of Massachusetts, Amherst, MA

Abstract: Previous findings in our laboratory suggest that a measure of early adolescent impulsive choice can predict late adolescent alcohol consumption selectively in female rats while no relationship has been detected for males.
This lead to the question of whether different mechanisms underly the measured impulsive choice in the two sexes.
Impulsive choice can have both perceptual and cognitive components; variation in impulsivity may then be explained either by individual differences in the perception of time, or how individuals assign value to delayed rewards.
To explore whether male and female impulsive choice was driven by different mechanisms, we used a peak interval task to assess the accuracy and precision of each rat's perception of time after they had been scored on an impulsive choice task.
Overall sex differences in time perception were subtle, but there were notable differences in how this perception related to impulsivity.
Accuracy of timing was correlated with impulsivity in males, but not in females.
Males less accurate in timing were more impulsive.
Overall, this suggests that much of the observed variation in male impulsive choice can be explained by variation in temporal perception.
Variation in impulsive choice in females, however, is likely due to cognitive components of how values are assigned to rewards.
This may contribute to the observation of impulsivity relating to alcohol consumption selectively in female rats.

Title: Nicotinic acetylcholine receptors are necessary for learning and response inhibition during negative occasion setting

Authors: *D. J. BUCCI, R. B. PUTNEY
Dartmouth Col., HANOVER, NH

Abstract: Our laboratory has carried out a series of studies in rats investigating the neural basis of a form of learning known as negative occasion setting. In a typical negative occasion setting procedure, a subset of trials consists of presentation of a tone followed immediately by food reward. On other trials, a light precedes the tone and no food is delivered. Normal adults learn to discriminate between these two trial types after ~8 training sessions, indicated by approaching the food cup in anticipation of receiving a reward when the tone is presented by itself, but inhibiting that response when the light precedes the tone. We have previously shown that nicotine administration reduces the number of sessions needed to learn the discrimination and also enhances the magnitude of discrimination between trial types specifically by reducing responding during the non-reinforced trials (MacLeod et al., 2006; 2010). In the present study, we tested whether acetylcholine, acting through nicotinic acetylcholine receptors, is necessary for negative occasion setting. Adult male Long-Evans rats were maintained at 85% free feeding body weight and treated with mecamylamine (2.0 mg/kg), a broad acting nicotinic acetylcholine receptor antagonist, 20 minutes before each daily training session. Compared to vehicle-treated control rats, those treated with mecamylamine needed more sessions to learn the discrimination and also did not exhibit as robust discrimination between the trail types. Together with the finding that rats with lesions of the prefrontal cortex are impaired in negative occasion setting (MacLeod and Bucci, 2010), these data indicate that acetylcholine, acting through cortical nicotinic receptors, may be necessary for learning to inhibit behavioral responses. Moreover, these findings may inform our understanding of inhibition deficits associated with disorders such as ADHD and schizophrenia; two conditions characterized by very high levels of nicotine use.

Title: Spinal nerve ligation (L5) leads to neuropathic pain and memory (Episodic, Spatial and Emotional) deficits in rats.

Authors: *P. JAYARAJAN, V. GOURA, R. ABRAHAM, R. MEDAPATI, R. YARAMASU, R. NIROGI
Suven Life Sci. Ltd, Hyderabad, India

Abstract: The most common form of chronic pain is neuropathic pain. Clinical evidence has revealed that chronic pain patients usually suffer from memory deficits. The aim of this experiment was to evaluate the cognitive performance of neuropathy rats using the various methods of preclinical memory testing. In the present study, Male wistar rats underwent tight ligation of the left spinal (L5) nerve and in sham control, nerves were exposed but not ligated. We assessed mechanical allodynia using manually held Von Frey monofilaments, the animals which developed allodynia condition were selected and tested for episodic memory functioning using novel-object-recognition task. Spatial learning was assessed using T-maze and emotional memory was assessed using passive avoidance paradigm. In this study SNL rats with allodynia condition showed episodic, spatial and emotional memory deficits in novel-object-recognition task, T-maze and passive avoidance respectively in comparison with sham control and naive rats. The memory deficit in neuropathic pain rats is similar to the clinical condition of patients suffering with chronic pain. Spinal nerve ligation (L5) can serve as a model to assess pain associated memory deficits.

Title: The effects of parity and estrogen on learning bias in female rats.

Authors: *D. HUSSAIN[1,2], B. WOODSIDE[2], W. G. BRAKE[2]
[1]Montreal, QC, Canada; [2]Psychology, Concordia Univ., Montreal, QC, Canada

Abstract: Previous studies have shown that estrogen (E) affects whether a hippocampus-mediated place (allocentric) or a striatum-mediated response (egocentric) memory system is

employed when searching for a food reward in a maze (Korol, 2004; Quinlan, Hussain, & Brake, 2008). It has been suggested that reproductive experience alters the response to E in a variety of systems. To investigate whether reproductive experience would alter the effect of E on response and place learning in a maze, in this experiment, 35 ovariectomized nulliparous (*n*=16; no reproductive experience) and primiparous (*n*=19; having had one litter of pups) Wistar rats were trained on place and response plus-maze tasks. Rats were also exposed to two hormonal treatment conditions: they received low 17β-estradiol (E2) or high E2 replacement. Results showed a 3-way significant interaction between task type, E2 level, and parity. In congruence with previous findings, low E2 nulliparous rats took significantly fewer days to reach criterion on the response task than on the place task. However, high E2 nulliparous rats learned both tasks in the same amount of time. Interestingly, the facilitatory effect of low E2 on response task learning seen in nulliparous rats was not observed in low E2 primiparous rats. In conclusion, E2 levels do dictate the rate at which female rats learn a response task, but only in those with no reproductive experience.

Title: Posttraining peripheral administration of cannabinoid 1 (CB1) receptor agonist WIN 55,212-2 impairs the consolidation of dorsolateral striatal-dependent habit memory

Authors: *J. GOODMAN[1,2], M. G. PACKARD[2]
[1]College Station, TX; [2]Dept. of Psychology, Texas A&M Univ., College Station, TX

Abstract: Extensive research indicates that the cannabinergic system plays a major role in modulating memory processes. Previous studies have shown that the peripheral administration of cannabinoid 1 (CB1) receptor agonists impair, whereas CB1 receptor antagonists enhance, learning in hippocampal-dependent memory tasks. In the present study, we examined the effects of posttraining peripheral administration of CB1 agonists and antagonists on the consolidation of a dorsolateral striatal-dependent habit memory task. Adult male Long-Evans rats were trained for 5 days (6 trials per day) in a stimulus-response version of the water plus-maze task, in which they were released from different start points and had to make the same body turn response (i.e.

turn right) at the choice point to reach the hidden escape platform. Immediately following training for the first two days, rats received peripheral (i.p.) injections of either the CB1 receptor agonist WIN 55,212-2 (3mg/kg), the CB1 receptor antagonist AM 251 (3mg/kg), WIN 55,212-2 (3mg/kg) and AM 251 (3mg/kg) concurrently, or the vehicle treatment alone. Relative to the vehicle-treated controls, WIN 55,212-2 significantly impaired memory consolidation. AM 251 did not affect task aquisition. However, the dose of AM 251 that was ineffective when given alone was sufficient to block the memory enhancing effects of WIN 55,212-2 when rats received concurrent drug injections. Taken together, the results indicate that peripheral administration of a CB1 receptor agonist impairs consolidation of dorsal striatal-dependent habit memory and that this effect can be reversed by co-administration of a CB1 receptor antagonist. Considering evidence that activity of the dorsal striatal habit memory system may underlie the persistence or development of some anxiety disorders, the findings are consistent with the hypothesis that pharmacological agents that target the cannabinergic system may prove useful in the treatment of human psychopathology

Title: Voluntary consumption of a high-energy diet prevents the memory-enhancing effects of acute stress in male rats

Authors: *J. DARLING[1], A. P. ROSS[2], M. B. PARENT[2]
[1]Neurosci. Inst., Georgia State Univ., Atlanta, ; [2]Neurosci. Inst., Georgia State Univ., Atlanta, GA

Abstract: Over the past 5 decades, caloric intake has increased by approximately 28% in the United States. High-energy diets (HEDs), which contain excessive calories, negatively impact the hippocampus and hippocampal-dependent memory by decreasing neuronal growth factors, neurogenesis, and synaptic communication. Previous studies from our lab suggest that HEDs impair memory in stressful tasks such as water maze but not during less stressful tasks such as spontaneous alternation. Moreover, HEDs increase secretion of the stress hormones epinephrine and corticosterone. As a result, we hypothesized that HEDs impair memory, in part, through diet-

induced increases in the acute stress response. To test this, adult male Sprague-Dawley rats were fed a high energy cafeteria-style diet containing choices of standard lab chow, animal lard, tap water, and a 32% sucrose solution for 4 weeks. Control rats were fed standard chow and tap water. The rats were then trained and tested in a low stress or high stress version of a spatial object recognition task. Surprisingly, the HED did not impair memory. Instead, the HED prevented the memory-enhancing effects of stress that were observed in control rats. These findings are significant because they raise the possibility that some previous results suggesting that HEDs impair memory may actually reflect deficits in stress-induced facilitation of memory. Future experiments should investigate the role of epinephrine and corticosterone in the interaction between HEDs and stress on hippocampal-dependent memory.

Title: Effects of the phosphodiesterase (pde) inhibitor papaverine on alcohol consumption in mice.

Authors: *P. J. WEBSTER[1], Y. JIANG[1], L. LUEPTOW[1], S. DOPPALAPUDI[1], J. LU[2], H.-T. ZHANG[1]

Abstract: Alcohol abuse and excessive alcohol consumption kill 79,000 people per year and cost the US more than $200 billion annually according to the CDC. Phosphodiesterase 4 (PDE4), one of the 11 PDE families (PDE1-11), has been implicated in alcoholism; however, it is not known whether other PDEs are also involved in alcohol drinking behavior. In the present study, we examined the role of PDE10, a dual substrate PDE enzyme that hydrolyzes both cyclic AMP (cAMP) and cyclic GMP (cGMP), in ethanol intake and preference utilizing papaverine, a PDE10 inhibitor. C57BL/6J mice, a strain known to drink alcohol excessively, were provided 24-h access to water and various levels of ethanol in a two-bottle choice test to gauge intake and preference for ethanol. In the drink-in-dark test, ethanol intake was measured during the time with the peak of ethanol drinking, followed by determination of the blood ethanol concentrations

(BECs). Treatment with the PDE4 inhibitor rolipram (0.5 mg/kg) decreased ethanol intake and preference in both two-bottle choice and drink-in-dark tests. Similarly, treatment with papaverine at doses of 10 and 30 mg/kg reduced ethanol consumption in the drink-in-dark test, although at lower doses (0.3-3.0 mg/kg) papaverine did not significantly affect ethanol consumption in either of the tests. Consistent with the reduced ethanol consumption, BECs were decreased by rolipram and papaverine (30 mg/kg). Given that pretreatment with papaverine or rolipram increases striatal cAMP levels, the results suggest that inhibition of PDE10 decreases ethanol consumption most likely via activation of cAMP signaling in the striatum. PDE10 inhibitors may be used for treatment of alcoholism and alcohol abuse [This work was supported by a research grant from NIH/NIAAA (AA020042)].

Title: Modeling varieties of list learning: Surface, structural and observational learning effects in macaques

Authors: *B. GASSER, M. ARBIB
Neurosci. Grad. Program, USC, Los Angeles, CA

Abstract: Macaques have been shown to be able to reproduce simultaneously presented images in an arbitrary order through trial-and-error learning. Slowly, across many lists, they develop task expertise that increases learning rate and performance on novel list instances. Expert monkeys passively observing other expert monkeys executing novel lists subsequently perform at higher rates on those lists compared to other novel list instances in control conditions. Additional probe lists support the conclusion that the monkeys learn to use ordinal representations to organize their performance. Here, we present a computational model demonstrating these varieties of learning and the representations the monkeys use to organize their behavior. We provide explanations for the development of task expertise and show how distributed regions in parietal and frontal cortices contribute to the

performance of the animal.   Crucially, we explain the observational learning effects not as a form of 'cognitive imitation' as first proposed, but as an enhancement of attention to learned, task-relevant features which develop associations to the cognitive structures only an expert monkey would have developed. We consider data on gaze-following, and neural responses sensitive to others' gaze direction, such as recently discovered LIP 'mirror neurons', as supporting the notion that monkeys are sensitive to the attentional states of others. We hypothesize this sensitivity contributes to the observational learning effects demonstrated.

Title: Evoked neural activity following environmental enrichment in young rats: A initial c-fos study

Authors: W. C. WHITE, Jr[1], A. M. FRENCH[1], A. M. DOYLE[2], D. E. COBB[2], *M. C. ZRULL[1]
[1]Psychol, [2]Honors Col., Appalachian State Univ., BOONE, NC

Abstract: Environmental enrichment (EE), or exposure to a setting with opportunities for investing and interacting with objects and conspecifics, can have an impact on the brain and behavior. While many EE studies have focused on changes in neural morphology, trophic factors and/or neurogenesis, relatively fewer investigations have addressed how EE might evoke neural activity related to learning and memory in young rats. We used c-fos to examine changes in numbers active neurons at baseline and after EE in amygdalao-hippocampal transition area (AHA), hippocampus, and entorhinal cortex (EntCtx). Young Long-Evans rats (n=8) were exposed to EE in cages with ramps, platforms, inanimate objects, and other rats for 1.5 hr/day for two of every three days between postnatal days (PND) 34 and 64. Age-matched rats (n=8) served as not enriched controls. Between PND 77 and 79 and immediately prior to sacrifice, 4 EE and 4 control rats spent 120 minutes in the enrichment cage, and 4 EE and 4 control rats spent 120 minutes in the quiet and dark. Brains were processed using immunohistochemistry to visualize the c-fos protein. Light microscopy and stereology were used to examine neural activation in the AHA, EntCtx, subiculum (SUB), dentate gyrus (DG), and CA1 region by counting fos-positive neurons in multiple sample frames per section and structure. When compared to rats not

experiencing EE immediately prior to sacrifice, an EE session evoked activity across examined brain regions for rats with and without a history of EE exposures. The EE session increased the number of active neurons from a high of 233% in AHA (p<.01) to a low of 93% (p<.06) in EntCtx for rats with an EE history, and the session increased active neurons from 275% in CA1 (p<.01) to 101% in DG (p<.07) for rats without an EE history. For rats not experiencing a final EE session before sacrifice, a history of EE reduced (-42% in AHA, p<.02; -49% in DG, p<.09; -32% in SUB, p<.07) or did not appreciably alter (-15% in CA1, +5% EntCtx) numbers of fos-positive neurons relative to not enriched controls. While a series of enrichment experiences reduced or did not alter neural activity levels in the investigated structures, a single EE exposure produced neural activation in all examined regions: AHA, EntCtx, SUB, DG and CA1. However, the greatest increase in number of activated neurons over non-evoked baseline differed for rats with (AHA, DG) and without (EntCtx, CA1) an EE history. Although the results suggest a need for more research, the data do suggest that self-directed, not explicitly rewarded investigation of and interaction with objects can activate neurons in brain regions known to be important for learning and memory.

Abstract: The effects of environmental enrichment (EE) on recovery from brain injury, enhancing learning and memory in adults, furthering brain development of infant and very young animals, and aiding the aging brain are often researched. EE has a positive impact on both brain and behavior in these settings. In this study, we began examining how EE affects behavior in rats that might be classified as from a "juvenile through adolescent" age group. Young Long-Evans rats (n=16) were exposed to EE in cages with ramps, platforms, inanimate objects, and other rats for 1.5 hr/day for two of every three days between postnatal days (PND) 34 and 64. Age-

matched rats (n=16) served as not enriched controls. Animals experienced behavioral testing between PND 66 and 75. On PND 78, 8 EE and 8 control rats were sacrificed after 2 hr in the quiet and dark, and those brains were processed to visualize the c-fos protein. Light microscopy and stereology were used to examine neural activation in the amygdala. During the final 3 minutes of a 5 minutes open field trial (1-m x 1-m), EE rats spent 130% more time in the field interior (i.e., not along the walls) than control rats (p<.01). Similarly, EE rats moved through 140% more squares of the field interior than non-EE rats (p<.01). During Trial 2 of a two-trial object preference task (3 minutes per trial, 15 and 30 minute delays), little difference in exploration of a novel object was observed between EE and control groups after a 15 minute delay. However, with a 30 minute delay, EE rats spent 20% less time exploring the field area adjacent to a novel object than control rats (p<.02) and showed a 28% decrease in the proportion of time in contact with the novel object (p<.02). Behavioral data suggest that rats experiencing EE during adolescence show less fear and explore more in a new environment than not enriched controls; however, EE rats exhibit some generalized adaptation to a novel object in that environment. Histology revealed differences in the number of active neurons, as indicated by the presence of c-fos, between EE and control rats. In basolateral amygdala of EE brains, there was a 34% reduction in active neurons relative to controls (p<.01). Lateral amygdala of EE brains showed an 18% reduction in fos-positive neurons relative to controls. EE appears to reduce baseline activity in amygdala, which correlates with reduced fear observed in behavioral tasks. While our results are certainly preliminary, the data seem to suggest that in our rat model enrichment during "juvenile through adolescent" development enhances exploratory behavior in general and may also promote adaptation to novelty within new and familiar environments.

Title: Synaptic changes in strength at the hippocampal formation during the acquisition of classical eyeblink conditioning in behaving rabbits

Authors: *A. CARRETERO, SR[1], R. PACHECO-CALDERÓN[1], R. SÁNCHEZ-CAMPUSANO[1], M. T. HASAN[2,3], J. M. DELGADO-GARCÍA[1], A. GRUART[1]

Abstract: Despite of the high number of studies focused in elucidating the role of the hippocampus in learning and memory processes, the precise contribution of hippocampal circuits to those processes is still a matter of discussion. In this presentation, we will show data of hippocampal recordings carried out in conscious rabbits during the classical conditioning of eyelid responses. Briefly, four groups of rabbits were used, one of them for baseline recordings, one for pseudoconditioning, and the other two for classical eyeblink conditioning using delay or trace conditioning paradigms. The conditioned stimulus (CS) consisted of a tone, whilst the unconditioned stimulus (US) consisted of an air puff. For the baseline group, electrophysiological recordings of hippocampal field excitatory post-synaptic potentials (fEPSPs) were carried out whitout applying any conditioning stimulus, to see the putative effects of enviromental (i.e., context) influences on activity-dependent changes at the different hippocampal synapses. In the case of pseudoconditioning, the CS and US were presented at random to check if uncoupled stimuli evoked the same synaptic changes than in their coupled presentation. A pair of electrical pulses were applied to the perforant path (PP), or CA3, during the CS and before the US in the case of the delay paradigm, or during the CS-US interval for trace paradigm, in the CS for pseudoconditioning, and in a fixed interval of time for baseline. The slope of evoked fEPSPs did not change across baseline sessions except for the CA3-CA1 synapse. similar results were observed in the pseudoconditioning case. In contrast, an increase, or a decrease, tendency was observed in conditioning sessions depending on the synapse and on the paradigm used. These results show that a constant context do not evoke significant changes in strength at the hippocampal synapses, in contrast with changes evoked by relevant but uncoupled stimuli, and to those evoked because of the associative learning proccess. To understand the role of dentate gyrus in memory acquisition and retrieval processes, we used recombinant adeno-associated viruses, which were equipped with doxycycline (Dox)-controlled genetic switches for reversible silencing of synaptic transmission. With this method, a single intraperitoneal injection of Dox induced synaptic silencing within two days and unsilencing after ten days. Preliminary results indicates the important role played by the dentate gyrus in the acquisition and retrieval processes.

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by cognitive impairment across several domains, with only modestly effective treatments currently available. For these reasons, continued drug discovery efforts are critical, and may be enhanced by establishing reliable preclinical animal models. Non-human primates (NHPs) are an ideal species for studying complex cognitive functions and can enhance the translatability of data into clinical applications. The objective of these studies was to establish pharmacologically sensitive cognitive tasks in NHPs that were relevant to AD. In these studies, we trained separate cohorts of animals (n=8/group) to perform a delayed match-to-sample (DMTS) test of working memory, a continuous performance test (CPT) of sustained attention, and a self-ordered spatial search (SOSS) test of spatial working memory and executive function using the CANTAB® system, and then we assessed the properties of several cognitive enhancing and impairing agents in these models. In DMTS, NHPs were presented with a sample stimulus and following a short (3-10 sec), medium (11-30 sec) or long (31-100 sec) delay period were presented with the sample and a distractor stimulus. A food reward was obtained following correct match to the original sample. DMTS performance accuracy decreased with increased delay times and acute administration of nicotine and donepezil produced dose-related improvements in the long delay of the test. In CPT, NHPs were presented with a target stimulus and two distractor stimuli and were trained to touch only the target stimulus until performance was near maximal levels (i.e., 90-100% accuracy). Administration of the muscarinic receptor antagonist, scopolamine, dose-dependently increased reaction times and impaired the performance accuracy, which was reversed by acute nicotine treatment. Finally, in the SOSS paradigm NHPs were presented with 2, 3, or 4 identical stimuli and trained to touch each of the stimuli once without repeating to receive a food reward. Performance accuracy decreased with increasing trial difficulty, an effect that was dose dependently worsened with scopolamine. Both donepezil and nicotine reversed the scopolamine impairments in the SOSS paradigm. These data demonstrate the pharmacological

sensitivity of using NHPs to assess cognitive function and support the utility of this approach for improving translatability of preclinical data into the clinic for novel therapeutic assessments.

Title: Source memory in the rat

Authors: *J. D. CRYSTAL, W. T. ALFORD, W. ZHOU, A. G. HOHMANN
Dept Psychological and Brain Sci., Indiana Univ., Bloomington, IN

Abstract: An emerging body of evidence suggests that rats have a detailed representation of earlier episodes. This includes information about what-where-and-when an earlier episode occurred (Zhou & Crystal (2009) *PNAS* 106:9525-9529) and the ability to retrieve information that was incidentally encoded and unexpectedly requested (Zhou, Hohmann & Crystal (in press) *Current Biology*). Here we asked if rats remember the origin of encoded information. Source memory includes a representation of the origin (i.e. source) of information and is related to episodic memory. We developed an animal model of external source monitoring by asking if rats can discriminate self-generated (walking along a runway, encountering food) and experimenter-generated (placement at a food site without walking) events. Placement occurred at randomly selected chocolate- or chow-baited arms of a radial maze in a daily study phase. The source by which chocolate was obtained at a study location determined chocolate replenishment at the same location in a subsequent test. Other randomly selected locations in study and test phases were baited with chow, were encountered by walking along the runways, and did not replenish. Rats revisited the chocolate location at a higher rate in replenishment than non-replenishment conditions. A transfer test to a different room suggests that performance was not based on memorization of a series of spatial contingencies, documenting some degree of flexibility in source memory. Manipulation of the retention interval between study and test suggests that

source memory decayed during delays whereas flavor-location memory was intact, providing a dissociation between source and other memories. We next asked whether temporary inactivation of the hippocampus, a brain region critical for episodic memory, would preferentially impair source memory. Bilateral intra-hippocampal infusions of lidocaine before the study phase eliminated source memory whereas performance in control conditions was intact. Our studies suggest that rats remember source information about flavors and locations of previously encountered food.

Title: Deep brain stimulation of the fornix and entorhinal cortex in an experimental model of memory impairment

Authors: *S. HESCHAM[1], L. LIM[1], A. JAHANSHAHI[1], J. PRICKAERTS[1], H. STEINBUSCH[1], A. BLOKLAND[2], Y. TEMEL[1]
[1]Neurosci., [2]Psychology and Psychopharmacology, Maastricht Univ., Maastricht, Netherlands

Abstract: Deep brain stimulation (DBS) is a surgical treatment involving the implantation of electrodes which give electrical impulses to specific parts of the brain. Recently, DBS in the region of the fornix has been applied in Alzheimer's disease with the purpose of improving or reducing the progression of memory loss. When structures of the memory circuitry are stimulated, DBS is thought to enhance neural activity and thus improves performance on memory tasks. In the following study, we implanted bilateral electrodes at the site of the fornix and entorhinal cortex in order to detect which stimulation parameters provide beneficial effects in spatial memory. Rats were then tested in the Object Location Task with the following conditions: (i) with attachment of stimulation cable (off stimulation), and (ii) with DBS at various amplitudes (50 μA, 100 μA and 200 μA), 100 μs pulse width and 100 Hz or 10 Hz stimulation frequency. Intraperitoneal scopolamine injections 30 min before the first trial were given to imitate memory impairment. DBS of both regions reversed the scopolamine effects in high current densities and showed superior memory performance when compared to sham rats. With the most efficient stimulation parameter rats did not show anxiety-like behaviour in the

Open Field and Elevated Zero Maze, suggesting no potential side effects regarding anxiety levels or general motor activity.

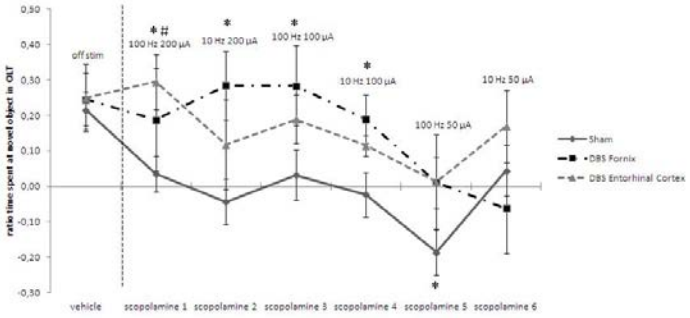

Figure: Ratio time spent at the new object for sham, DBS Fornix and DBS Entorhinal Cortex rats in the OLT. In the first session stimulation was off and saline was injected in all rats. In the following 6 sessions scopolamine was injected and DBS rats were stimulated with the parameters mentioned above. Sham rats only received scopolamine and were not stimulated. Significant effects were found for DBS Fornix rats (*) in high current densities (200 and 100µA) and independent of frequency (100Hz or 10Hz). DBS Entorhinal cortex rats (#) showed enhanced spatial memory at 100Hz and 200µA.

Title: Sex differences in operant responding and survivability following xposure to space radiation.

Authors: K. L. CARRIHILL-KNOLL[1], *B. M. RABIN[1,2], B. SHUKITT-HALE[2]
[1]Univ. Maryland Baltimore County, BALTIMORE, MD; [2]Human Nutr. Res. Ctr. on Aging, USDA-ARS, Boston, MA

Abstract: On exploratory class missions, such as a mission to Mars, astronauts will be exposed to types and doses of radiation (galactic cosmic rays [GCR]) which are not experienced in low earth orbit where the space shuttle and International Space Station operate. Despite the fact that

the crew on such a mission is likely to be composed of both male and female astronauts, little research has been done on the effects of the space radiation environment on females.
As part of a series of experiments on the long-term effects of exposure to heavy particles on cognitive performance using a ground-based model for exposure to GCR, 2-month old male and female rats were exposed to 12C and 56Fe particles. The rats were maintained in the animal facility at UMBC for up to 24 months following irradiation. They were checked daily for the development of tumors or other health problems. The rats were euthanized if an evident tumor was bleeding or had grown to 5 cm in size, if the rat showed signs of distress or pain, or if the rats stopped eating or showed a general deterioration in health.
Both male rats and ovariectomized female rats with estradiol implants showed an equivalent disruption of operant responding following exposure to both particles. However, the female rats exposed to either particle survived for a significantly longer period of time than male rats. Although the mechanisms underlying these differences in the effects of exposure to heavy particles on survival have yet to be elucidated, the results of these experiments may have implications for astronauts on exploratory class missions.

Title: Anterior vs. posterior lesions of the pedunculopontine tegmentum produce differential deficits in sensory gating and higher cognitive function

Authors: *J. ROBINSON, S. SCHMID
Neurosci., Univ. of Western Ontario, London, ON, Canada

Abstract: The pedunculopontine tegmentum (PPT) is part of the brainstem cholinergic system, composed of both cholinergic and non-cholinergic (Glu and GABA) cells. The posterior PPT receives sensory input whereas the anterior PPT receives forebrain (basal ganglia, amygdala) input, and there are both ascending and descending efferent connections. The proposed role of the PPT is two-fold: first, ascending connections regulate activity of thalamic and basal ganglia nuclei in relation to timing of sensory information, and second, descending connections provide forebrain machinery (i.e. basal ganglia) access to locomotor machinery in the brainstem and are

involved in sensory processing. Ascending cholinergic projections to the dopaminergic neurons of the substantia nigra (SNc) regulate timing of dopamine release in relation to sensory information, a process important for associative learning. Descending cholinergic projections to the brainstem are involved in prepulse inhibition (PPI), a basic form of sensory gating in which the startle response of a reflex-inducing startle pulse is attenuated when preceded by a sub-threshold stimulus, and potentially habituation. Disrupting ascending cholinergic projections should impair associative learning, and disrupting descending cholinergic projections should impair PPI and/or habituation. We lesioned the anterior or the posterior PPT bilaterally by microinjections of ibotenic acid, followed by testing of PPI and habituation in startle boxes, spatial memory in a Barnes maze, and locomotor behaviour in locomotor boxes. Preliminary results suggests that rats with posterior PPT lesions show impaired long-term habituation ($p = 0.033$) while short term habituation is unaffected. Interestingly, no effects on PPI were observed using 75dB or 85 dB prepulses and 10, 30, or 100 ms interstimulus intervals. In the Barnes maze test, animals with anterior and posterior lesions displayed a trend to slower learning than saline injected animals on day 1, and spatial memory was disrupted on day 12. Since the PPT degenerates significantly in Parkinson's disease and is currently a candidate for deep brain stimulation, understanding PPT function is of high clinical value. Future experiments will use a specific toxin for cholinergic neurons in order to separate cholinergic from non-cholinergic PPT function.

Title: Neurogenomics of social eavesdropping in zebrafish

Authors: *R. A. DE ABREU[1,2], R. F. OLIVEIRA[1,2]
[1]Champalimaud Neurosci. Programme, Lisbon, Portugal; [2]Unidade de Investigação em Eco-Etologia, ISPA - Inst. Universitário, Lisbon, Portugal

Abstract: In social species individuals need to continuously adjust their behavior as a function of the available social information, which can be collected first-hand by directly interacting with other individuals, or by observing others (social learning). We are using the model system zebrafish (Danio rerio) to study the role of social learning on behavioral plasticity and how changes in neurogenomic states allow for adaptive plastic responses to a fluctuating social environment. This plasticity may be achieved by rewiring or by biochemically switching nodes of the neural network underlying social behavior in response to perceived social information. Therefore, at the molecular level, it depends on the social regulation of gene expression, so that different neurogenomic states correspond to different behavioral responses and the switches between states are orchestrated by signaling pathways that interface the social environment and the genotype. Previous work in our lab has shown that the perceived outcome of agonistic social interactions in zebrafish has a major impact in the brain transcriptome profile that mediate the effects of prior social experience on subsequent behavior (i.e. winner and loser effects). Here we investigate if these effects are also present in bystanders who watch but do not participate in social interactions. For this purpose we established a protocol with three conditions, where isolated male zebrafish either: (1) observe an agonistic interaction between a pair of conspecifics; (2) observe a non-interacting conspecific male dyad; or (3) observe an empty adjacent tank. Brain gene expression levels are analyzed using the Affymetrix GeneChip Zebrafish Genome, which covers over 14.900 zebrafish transcripts. Behavior measures are obtained using an automated video tracking system. This study will help establish the impact of social eavesdropping at the transcriptome level, opening the way to future studies on the mechanisms of social learning in zebrafish by contrasting it with equivalent asocial learning mechanisms (e.g. stimulus enhancement). The comparison of the different profiles of gene expression across these studies will allow to test if social learning shares its neurogenomic mechanism with that of its corresponding asocial learning form.

Abstract: The striatum (STR) and medial frontal cortex (MFC) have been implicated in the control of motivated behavior. The functional output of STR and MFC circuitry is regulated in very complex ways, in part by the expression and activity of GABAergic interneurons. Both interneurons and projection neurons within these regions receive prominent dopamine (DA) input and express DA receptors as early as mid-gestation. Also, disruption of DA receptors and/or signaling early in development modulates GABAergic neuronal migration and differentiation. Our group and others have previously implicated D1 receptors in these responses; we now investigate potential roles for the D2 receptor (D2R) in interneuron development and function. First, we used immunohistochemistry to identify alterations in neuron-specific markers within the STR and MFC in D2R knockout (KO) mice. Significant increases in GAD67+ (GABAergic) neurons were found in D2R KO mice in both the STR and MFC. Parvalbumin, a marker of a subpopulation of fast-spiking GABAergic interneurons, was also significantly increased in both brain regions. No changes in parvalbumin or GAD67 were apparent in the somatosensory cortex, demonstrating neuroanatomical specificity. We also conducted several behavioral studies in wildtype and D2R KO mice. As previously described, D2R KO mice were significantly hypoactive in an open field. D2R KO mice also expressed reduced immobility in a tail suspension test, suggesting that genetic loss of D2 receptors may produce an antidepressant-like response. Ongoing studies attempt to relate our observed changes in GABAergic neurons with our behavioral findings. Taken together, these data demonstrate that the D2 receptor plays an important role in GABAergic interneuron expression in the MFC and STR and that perturbations of this receptor produce functional outcomes.

Title: Impulsive action is regulated by the infralimbic cortex; $D_{1/5}$ dopamine receptors in the infralimbic cortex are involved in milnacipran-enhanced inhibitory control

Authors: I. TSUTSUI-KIMURA[1], *Y. OHMURA[1], T. IZUMI[1], H. KUMAMOTO[1], T. YAMAGUCHI[2], T. YOSHIDA[1], M. YOSHIOKA[1]
[1]Neuropharm., Hokkaido Univ. Grad. Sch. of Med., Sapporo, Japan; [2]Pharmacol., Fac. of Pharmaceut. Sciences, Nagasaki Intl. Univ., Sasebo, Japan

Abstract: Disruption of inhibitory control of impulsive behavior is an intolerable symptom in various psychiatric disorders and also could be a risk factor for suicide, pressing for understanding the neural basis of inhibitory control. Previous lesion studies have demonstrated that the rat infralimbic cortex (IL), the ventral portion of the medial prefrontal cortex (mPFC), is implicated in inhibitory control. In addition, we previously revealed that nicotine, a major addictive component of tobacco, disrupted inhibitory control via stimulating α4β2 nicotinic acetylcholine receptor in the IL, but not the prelimbic cortex, the dorsal portion of the mPFC. We recently found that acute milnacipran, an antidepressant and a serotonin/noradrenalin reuptake inhibitor, could enhance inhibitory control in rats. However, the neural mechanisms underlying the effects of milnacipran on impulsive action remain unclear. Milnacipran increases not only extracellular serotonin and noradrenalin but also dopamine specifically in the mPFC.Our goals were to confirm the role of the IL in inhibitory control and to identify whether $D_{1/5}$ and/or $D_{2/3}$ receptors in the IL mediate the milnacipran-enhanced inhibitory control in the 3-choice serial reaction time task (3-CSRTT).We recorded single-unit activity in the IL of rats performing the 3-CSRTT. Fifty-six units were isolated from 8 rats and among which 38 (68%) of units were related to inhibitory control. Inactivation of the IL of other 9 rats by bilateral injection of muscimol (0, 0.1, 0.5 μg/side), a $GABA_A$ agonist, significantly disrupted inhibitory control in the 3-CSRTT. Other 20 rats were bilaterally injected with SCH23390, a selective $D_{1/5}$ receptor antagonist, (0.3 or 3 ng/side) or eticlopride, a selective $D_{2/3}$ receptor antagonist, (0.3, 1, 3 μg/side) into the IL after acute administration of milnacipran (10 mg/kg, i.p.). Intra-IL SCH23390 injections reversed the milnacipran-enhanced inhibitory control, while injections of eticlopride into the IL failed to block the effects of milnacipran on inhibitory control in the 3-CSRTT.These results suggest that the rat IL has a critical role in inhibitory control and $D_{1/5}$ receptors in the area are responsible for acute milnacipran-enhanced inhibitory control in the 3-CSRTT.

Title: Dopamine release in the prefrontal cortex is paradoxically smaller when preferred rather than non-preferred reward is delivered during a working memory task - a monkey microdialysis study

Authors: *T. KODAMA[1], K. HIKOSAKA[2], Y. HONDA[1], T. KOJIMA[1], M. WATANABE[1]
[1]Dept Physiological Psychology, Tokyo Metropol Inst. Medicalsci, Setagaya, Tokyo, Japan;
[2]Dept. of Sensory Sci., Kawasaki Univ. of Med. Welfare, Kurashiki, Japan

Abstract: Introduction: It has been well documented that optimal level of dopamine in the mammalian prefrontal cortex (PFC) is critical for higher cognitive control of behavior. We previously reported increase of dopamine release in the primate lateral PFC during the working memory (WM) task. Microinjection of dopamine and stimulation of dopamine D1 receptor in the PFC, dose-dependently modulates (enhances or suppresses) WM-related neuronal activity. When reward is delivered, increase of dopamine release is observed in many areas of the mammalian brain including PFC. It has also been indicated that preferred as compared with nonpreferred reward induces enhanced WM-related neuronal activity. We thus thought that there should be more dopamine release in the PFC when more preferred as compared with less preferred reward is delivered during the WM task.
Methods: Three monkeys were trained in a WM (spatial delayed alternation) task. We examined dopamine release while the monkey was (1) performing the WM task with a non-preferred reward (water), (2) performing the WM task with a preferred reward (grape juice) and (3) sitting quietly without task performance and without reward (no-reward). After insertion of the microdialysis probes into the PFC, we obtained dialysate samples for the next two consecutive days during the (1) water reward, (2) juice reward and (3) no-reward periods. Sampling time for each condition was 20 min. The dopamine level in the perfusate was determined by high-performance liquid chromatography and electrochemical detection.
Results and Discussion: Monkeys performed the WM task in more than 98 % correctness with the reaction time significantly shorter in juice than in water reward trials. Contrary to our expectation, dopamine level was higher when water was given than when juice was given as a reward. Considering our previous study indicating no dopamine change during the non-WM control task performance (where cognitive load was small but the reward was delivered),

dopamine release in the PFC appears to be more concerned with cognitive requirement rather than reward per se. It is speculated that when the monkey is less motivated to perform the task during the non-preferred reward condition, more cognitive resources may be required to perform the WM task and thus there would be more dopamine release.

Title: [^{18}F]FDG PET as a potential biomarker for mapping dopamine D1 receptor-induced changes in brain regional glucose metabolism associated with improvement of working memory.

Authors: *K. KUSZPIT[1], R. KOZAK[2], A. ZHU[1], G. CURRIER[1], D. MCGINNIS[2], V. GUANOWSKY[2], P. A. SEYMOUR[2], K. ZASADNY[1], L. CHEN[1], D. GRAY[3]
[1]PTx Precision Medicine, Preclinical BioImaging, [2]Neurosci. Res. Unit, Dept. of Psychiatry, [3]Neurosci. Medicinal Chem., Pfizer, Inc., Groton, CT

Abstract: Schizophrenia is a disabling neuropsychological illness causing substantial cognitive deficits including working memory (WM) deficits. Dopamine D1-like receptors (D1r) are the most expressed dopamine receptors in the neocortex, including the medial prefrontal (mPFC)/cingulate cortex. Studies in nonhuman primates have shown that WM, studied during delayed response paradigms, is critically dependent on appropriate stimulation of D1 receptors in the mPFC/cingulate cortex (Goldman-Rakic 2000, 2004). This finding suggests that targeting the activation of D1r is a valuable therapeutic intervention for treating cognitive deficits in schizophrenia. [^{18}F]FDG PET provides a non-invasive, *in vivo* measure of relative regional glucose metabolism that can be used to assess regional brain function in a variety of states, including the acute responses to psychoactive drugs. In the current study, we aimed to determine if [^{18}F]FDG PET could detect D1r-modulated changes in glucose metabolism in brain regions associated with WM. Forty-eight male rats were divided into four groups tested with either vehicle, A77363 (1mg/kg, sc) or SKF-38393, (0.32 & 3.2mg/kg, sc), D1-like receptor ligands that have different degrees of intrinsic efficacy (full and partial agonist respectively). Although both drugs showed similar capacity to reverse ketamine-induced impairment in a radial arm maze task, a rodent task of working memory, only A77393 increased locomotor activity in a

dose-responsive manner, while SKF-38393 had no effect. [^{18}F]FDG PET was performed on fasted rats using a Siemens Focus 220 microPET scanner at 60 mins post [^{18}F]FDG injection (~47 MBq, iv). PET data were reported in terms of the standard uptake values (SUV). SUV images for each animal were normalized to each animal's own mean whole brain uptake. PET imaging showed significantly reduced FDG uptake ($p<0.05$) in the mPFC/cingulate cortex of both drug-treated groups as compared to vehicle controls. However, the magnitude of the effect was related to agonist efficacy; A77363 showed significant further reduction in [^{18}F]FDG uptake in mPFC/cingulate cortex compared to SKF 38393. These finding suggest that this method can be used to assess dopamine D1-like agonist activity based on their effect sizes and demonstrates the utility of [^{18}F]FDG PET in mapping D1 agonist-induced changes in brain regional glucose metabolism associated with optimal prefrontal functioning. All animal procedures conducted were approved by an institutional review committee (IACUC).

Title: An astrocyte response to dopamine depletion of the prefrontal cortex

Authors: *P. J. VOLLBRECHT[1], H. WANG[2], A. DEUTCH[2]
[1]Neurosci., [2]Psychiatry, Vanderbilt Univ., Nashville, TN

Abstract: Dopamine loss in the prefrontal cortex (PFC), as has been reported in schizophrenia, results in a marked decrease in pyramidal cell (PC) dendritic spine density. The mechanisms through which cortical dopamine loss decreases the number of dendritic spines are not known. Changes in glutamate signaling are a major determinant of dendritic spine morphology and number. Over the past decade it has become clear that astrocytic proteins play a major role in regulating extracellular glutamate levels. In particular, the glial-specific glutamate transporter GLT-1 (EAAT2) and the group II metabotropic glutamate receptors (mGluRs), which are

expressed by both astrocytes and neurons, are key players in modulating extracellular glutamate levels. We determined if PFC dopamine depletion results in altered levels of astrocytic and neuronal proteins involved in extracellular glutamate homeostasis. Adult male rats received 6-hydroxydopamine (6-OHDA) lesions of the A10 dopamine neurons and were sacrificed three weeks later. Prefrontal cortical dopamine depletion significantly increased both GLT-1 and mGluR2/3 levels in membrane fractions from the prelimbic cortex, suggesting an enhanced clearance of extracellular glutamate in the PFC. The magnitude of the changes in GLT-1 and mGluR2/3 levels are inversely correlated with the extent of dopamine depletion in the PFC. Stereological assessment of GFAP-ir astrocytes uncovered no change in the number of astrocytes, nor were GFAP protein levels changed in the PFC. In contrast to the increased levels of the astrocytic protein GLT-1 and mGluR2/3, we did not observe significant changes in the expression of neuronal proteins involved in glutamate signaling, including AMPA and NMDA receptor subunits. These data suggest that dopamine depletion of the PFC leads to alterations in astrocytic regulation of extracellular glutamate, which may in turn determine dendritic spine plasticity.

Title: Synaptic activity unmasks dopamine d2 receptor modulation of a specific class of layer v pyramidal neurons in prefrontal cortex

Authors: *S. GEE, I. ELLWOOD, V. SOHAL
UCSF, San Francisco, CA

Abstract: Dopamine D2 receptors (D2Rs) play a major role in the function of the prefrontal cortex (PFC), and may contribute to prefrontal dysfunction in conditions such as schizophrenia. Here we report that in mouse PFC, D2Rs are selectively expressed by a subtype of layer V pyramidal neurons that have thick apical tufts, prominent h-current, and subcortical projections. Within this subpopulation, the D2R agonist quinpirole elicits a novel afterdepolarization that generates voltage fluctuations and spiking for hundreds of milliseconds. Surprisingly, this afterdepolarization is masked in quiescent brain slices, but is readily unmasked by physiologic levels of synaptic input which activate NMDA receptors, possibly explaining why this phenomenon has not been reported previously. Notably, we could still elicit this afterdepolarization for some time after the cessation of synaptic stimulation. In addition to NMDA receptors, the quinpirole-induced afterdepolarization also depended on L-type calcium channels and was blocked by the selective L-type antagonist nimodipine. To confirm that D2Rs can elicit this afterdepolarization by enhancing calcium (and calcium-dependent) currents, we measured whole-cell calcium potentials that occur after blocking sodium and potassium channels, and found quinpirole enhanced these potentials, while the selective D2R antagonist sulpiride had the opposite effect. Thus, D2Rs can elicit a calcium-channel-dependent afterdepolarization that powerfully modulates activity in specific prefrontal neurons. Through this mechanism, D2Rs might enhance outputs to subcortical structures, contribute to reward-related persistent firing, or increase the level of noise in prefrontal circuits.

Title: Defining the interspecies exposure-receptor occupancy-cognitive disruption relationship of (±)-ketamine

Authors: *C. L. SHAFFER, S. M. OSGOOD, D. L. SMITH, P. TRAPA, S. GRIMWOOD
Neurosci. Res. Unit, Pfizer Inc., Cambridge, MA

Abstract: Glutamate dysregulation and *N*-methyl-D-aspartate (NMDA) receptor hypofunction are hypothesized key contributors to the psychopathology of schizophrenia and the various cognitive impairments in this disease. The NMDA receptor antagonist (±)-ketamine has been shown to produce schizophrenia-like symptoms and cognitive impairment, including working

memory deficits, in healthy humans. Thus, (±)-ketamine has been used in rats and nonhuman primates (nhp) to replicate specific cognitive deficits in schizophrenia, and such models have been used to study potential nootropic agents. Accordingly, this work evaluates the interspecies (i.e. rat, nhp and human) translatability of (±)-ketamine-mediated cognitive disruption via normalization to NMDA receptor occupancy (RO); both (±)-ketamine and its 7-fold less potent active metabolite (±)-norketamine were evaluated simultaneously following (±)-ketamine administration. To achieve this, unbound compound concentrations (both plasma and brain) and observed NMDA RO from rat in vivo RO studies using [^{3}H]MK-801 were analyzed by both direct response and receptor-binding kinetic models to afford matrix-specific IC_{50} and K_D, respectively. Assuming similar neuropharmacokinetics and respective ligand-receptor binding kinetics across species, these values allowed estimates of NMDA RO over time using (±)-ketamine and (±)-norketamine plasma exposures following the administration of cognitively impairing acute doses of (±)-ketamine in rats (10 mg/kg, SC) or nhp (1 mg/kg, IM). This same methodology transformed published human plasma data at a (±)-ketamine dose (0.23 mg/kg IV bolus + 0.5 mg/kg infusion) impairing working memory clinically. Collectively, the presented data provide insights into the translational pharmacologic relationship of NMDA RO to cognitive disruption for (±)-ketamine in rats, nhp and humans.

Title: Environmental enrichment: differential effects on drugs on object recognition memory in rats

Authors: *A. BLOKLAND[1], S. AKKERMAN[2], J. PRICKAERTS[2]
[1]Fac. Psychol, Maastricht Univ., Maastricht 6200 MD, Netherlands; [2]Dept. of Psychiatry and Neuropsychology, Maastricht Univ., Maastricht, Netherlands

Abstract: Drug effects are usually evaluated in animals that are housed under standard conditions. However, it is assumed that rats raised in an enriched environment (EE) may be more

comparable to the human condition as compared to rats raised in a standard laboratory condition. Many studies have shown different expressions of biochemical markers in EE rats as compared to standard housed (SH) rats. Also, drug effects in various animal models differ between rats with different rearing histories Therefore the validity of the use of standard housed animals in drug research could be questioned. Moreover, there are no studies that have studied the effects of cognition enhancers in EE rats. In the present study we examined the effects of scopolamine and a PDE5 inhibitor on object recognition performance in standard housed and EE rats. SH and EE rats performed equally well when using a 1- delay but the EE rats outperformed the SH rats when using a 24-h delay. Scopolamine had similar effects in both standard housed and EE rats at the doses tested (0.03-0.3 mg/kg). As expected, a PDE5 inhibitor improved memory performance in SH rats. However, PDE5 inhibition did not improve memory performance in EE rats when using a 24-h delay (ceiling effect). Even when applying a 48-h interval PDE5 inhibition did not improve object recognition in the EE rats. These data suggest that scopolamine was effective to impair memory performance in EE and SH rats. However, memory enhancement was not found in EE rats. These data question the use of standard housed animals for the development of cognition enhancers in animal research.

Title: Analysis of the effects of chronic treatment of ayahuasca on memory and anxiety in rats.

Authors: *V. M. FAVARO[1], M. YONAMINE[2], M. G. M. OLIVEIRA[1]
[1]Dept. of Psycobiology, Federal Univ. of São Paulo, São Paulo, Brazil; [2]Univ. of São Paulo, São Paulo, Brazil

Abstract: Ayahuasca is a hallucinogenic beverage that combines the action of the agonist serotonin N,N-dimethyltryptamine (DMT) from Psychotria viridis with inhibition of monoamine oxidase (MAO) induced by beta-carbonyls from Banisteriopsis caapi. In recent years, the legalization of consumption of the drink in a religious context provided an increase in the

consumption of ayahuasca chronically worldwide, arousing interest of the scientific community about the effects of drink on the central nervous system. Thus, this study investigated the effects of chronic treatment of ayahuasca on memory and anxiety in rats using different behavioral models. We used male Wistar rats (3 mo) weighing 250-350g. Ayahuasca was freeze-dried and the doses used were 120, 240 and 480 mg/kg (p.o) and tap water as control (N=12/group). Chronic treatment based on the administration of a daily dose of tea for 30 days. The animals were placed on the elevated plus maze (EPM) for 5 minutes, 48 hours after the last administration of the tea. After an interval of 30 minutes, the animals were trained on tone fear conditioning task (TFC), where they received 5 pairings of sound (5s) + shock (1s - 0.6 mA) for 6 minutes and 24 hours after training, animals were exposed to the same context of training for 5 minutes, and 48 hours after training, the same animals were placed in a different context where the sound (5s) was presented 5 times for 6 minutes. The paradigm of the Morris water maze (MWM) - spatial version was initiated 48 hours after last administration of ayahuasca with a new group of animals and was based on five days of training (4 trials - 1min/animal), followed by a test day (one trial - 1min/animal) in which the platform was removed. We found no significant differences between groups in the number of entries and time spent in open arms of the EPM. In contextual fear conditioning (CFC), the animals that received a dose of 120 mg/kg had a greater total time of freezing when compared to other groups. In TFC there were no significant differences in freezing time between groups. In MWM we found no significant differences in performance between groups. The behavioral data showed that chronic administration of ayahuasca improved the performance of animals that received a dose of 120 mg/kg in the CFC test. Furthermore, there was no change in anxiety levels, or performance of animals in MWM and TFC tests.

Title: Central administration of angiotensin IV rapidly enhances novel object recognition among mice

Authors: *J. P. MCLAUGHLIN, S. O. EANS, E. MIZRACHI, K. J. REILLEY, M. L. GANNO, J. J. PARIS
Torrey Pines Inst. For Mol. Studies, Port Saint Lucie, FL

Abstract: Angiotensin IV (Val^1-Tyr^2-Ile^3-His^4-Pro^5-Phe^6), a metabolite of Angiotensins II and III, has demonstrated potential cognitive-enhancing effects. The present investigation aimed to assess and characterize: (1) angiotensin IV's dose-dependent effects for cognitive-enhancement in a C57BL/6J mouse model of a one-day novel object recognition task, (2) the time-course for these effects, and (3) the identity of residues in the hexapeptide important to these effects. Assessment of C57BL/6J mice in a novel object recognition task demonstrated that prior administration of angiotensin IV (0.1, 1.0, or 10.0 nmol, i.c.v.) significantly enhanced novel object recognition in a dose-dependent manner, with 0.1 nmol angiotensin IV proving the lowest, most efficacious dose as compared to vehicle administration. These effects were time dependent, as improved novel object recognition was observed when angiotensin IV (0.1 nmol, i.c.v.) was administered 10 min prior to the onset of the novel object recognition task, but not when administered 20 or 30 min prior to testing. Rotorod testing demonstrated no alterations of locomotion induced by any dose of angiotensin IV tested. A targeted alanine scan revealed that Ala-Val^1 replacement attenuated effects on novel object recognition, whereas Ala-Pro^5 replacement did not. Pretreatment with the angiotensin IV antagonist, divalinal-angiotensin IV, demonstrated the involvement of the angiotensin IV system in these behavioral effects. Overall, these data demonstrate that angiotensin IV produces a rapid enhancement of associative learning and memory performance in a mouse model, dependent on the valine residue in the first position of the peptide. Given reports of the conserved distribution of angiotensin IV binding in brain regions associated with mnemonic performance, the present results further support the potential of this ligand as a therapeutic to enhance cognition.

Title: Early life handling effects in an anxiety disorder model.

Authors: *M. L. RIBEIRO
Rio De Janeiro, Brazil

Abstract: The anxiety behavior is influenced by several factors, including environment, genetic and the interaction between them, which is the aim of this work. The neonatal handling procedure was performed with the Carioca rats, an anxiety disorder Wistar rat model, developed through selective lines matching based in a task of contextual fear conditioning, which gives rise to two different lines: CHF (Carioca High Freezing) and CLF (Carioca Low Freezing). In the neonatal handling study, CHF and Control rat pups were manipulated from PND1-21, daily, for 3min/animal (CHFH and CTRH groups), and evaluated in the Elevated Plus Maze (EPM) at PND28; other two groups did not received handling (CHF and CTR groups). A two-way ANOVA followed by LSD post-hoc test showed that he CHFH rats had the lowest rate entries in BA: CTR (Mean 4, SEM 0 ± 50, 73), CTRH (5.27 ± 0.52), CHF (3.44 ± 0.77) and CHFH (1.71 ± 0.75); $F(3,36) = 4.54$; $p < 0.05$. The CHF group had fewer entries in the BF than the CTR groups, independent of manipulation: CTR (8.70 ± 3.76), CTRH (11.00 ± 1.07), CHF (6.11 ± 0.81), CHFH (4.14 ± 0.86); $F(3,36) = 9.92$; $p < 0.05$. The procedure of handling reduced the relative frequency of entries in the BA in the CHFH group, without effect on group CTRH: CTR (31.87 ± 3.76), CTRH (32.51 ± 1.86), CHF (35.09 ± 5.89), CHFH (19.18 ± 6.98); $F(3,36) = 2.04$; $p < 0.05$. CTRH rats explored longer the center of the EPM: CTR (40.50 ± 3.99), CTRH (62.00 ± 6.79), CHF (27.56 ± 5.58) and CHFH (32.71 ± 11.18); $F(3,36) = 5.42$, $p < 0.05$. The CHF and CHFH groups spent less lime exploring the BA: CTR (14.80 ± 2.89), CTRH (15.30 ± 2.13), CHF (11.19 ± 2.93) and CHFH (4.33 ± 2.22); $F(3,36) = 3.27$; CHFH < CTR = CTRH, no significant difference between CHF and CHFH; $p < 0.05$. Conclusions: Animals of the CHF Group - manipulated or not - have lower rates of exploration of anxiogenic areas of the EPM compared with control groups. Manipulation, although not presenting significant variations in behavior related to anxiety, was able to change the ambulatory behavior (BF) and risk assessment (Time Center), but only in control rats. The handling has significantly changed the measure of entries in the BA group CHFH, reducing it, which is different than expected, indicating that these animals show a different behavior. The handling model was unable to reverse the behavioral pattern of anxiety in the experimental group CHF. The authors thank CAPES, FAPERJ and CNPq for the financial support.

Title: Genetic variant BDNF (Val66Met) polymorphism is associated with volumetric brain changes in the mouse

Authors: *J. SCHOLZ[1], A. VOINESKOS[2], F. S. LEE[3], S. SPRING[1], J. P. LERCH[1]
[1]Mouse Imaging Ctr. (mice), Hosp. For Sick Children, Toronto, ON, Canada; [2]Ctr. for Addiction and Mental Hlth., Dept of Psychiatry, Univ. of Toronto, Toronto, ON, Canada; [3]Dept. of Psychiatry, Weill Cornell Med. College, Cornell Univ., New York, NY

Abstract: Introduction
Brain-derived neurotrophic factor (BDNF) is a neurotrophine involved in growth and differentiation of new neurons and synapses. A single-nucleotide polymorphism in the BDNF gene (Val66Met) allows to study how BDNF contributes to affective disorders. In humans a methionine (Met) substitution for valine (Val) has been associated with changes in brain anatomy (Bueller et al, 2006) and memory (Hariri et al., 2003). In the mouse model decreased dendritic complexity in the dentate gyrus and increased anxiety-related behaviour has been observed (Chen et al., 2006). Here we test for volumetric brain changes across the whole brain between wild type (ET), heterozygous, and homozygous mice with post mortem magnetic resonance imaging (MRI). We hypothesize that the previously observed decreased neuronal complexity is associated with decreased volume.
Methods
69 (36 female) fixed mouse brains were examined, 43 WT, 13 (+/Met), 13 (Met/Met). MRI Acquisition: T2-weighted, 3-D fast spin-echo sequence (TR/TE = 2000/14 ms, 2 averages, field-of-view 14 x 14 x 25 mm3, matrix size = 250 x 250 x 450, imaging time = 11 h) (Lerch et al. 2011). Analysis: Images were aligned non-linearly (Lerch et al. 2011). The smoothed (FWHM 0.5 mm) Jacobians of the warp fields were used in an Anova design to test voxel-wise for differences between the three groups. Threshold-free cluster enhancement was used to correct for multiple comparisons (Smith et al., 2009). Voxels that passed the $p<0.05$ threshold were deemed significant.
Results
The voxel-wise test revealed that the three groups differed significantly in the area of the nucleus accumbens bilaterally ($p<0.01$, corrected). Averaging over the two significant clusters showed that the volume of the nucleus accumbens was significantly decreased in homozygous (10%, $p<0.01$), but not in heterozygous (4%, $p=0.21$). The was no significant effect of sex ($p=0.15$), but a significant interaction between sex and gene ($p=0.005$). WT and heterozygous males had smaller nuclei then their female counterparts. This relationship seemed to be reversed in

homozygous.
Conclusion
The nucleus accumbens plays an important role in processing reward and fear stimuli and has been implicated in vulnaribility to addictions. In humans deep brain stimulation of the right nucleus accumbens has shown to decrease the severity of anxiety disorders (Sturma 2003). It is possible that the polymorphism in the BDNF gene affects the structural organization of the nucleus accumbens resulting in increased anxiety. Future studies will investigate this link between behaviour and brain structure and might help to improve treatments of anxiety and addiction in the future.

Title: The object retrieval test in the non-human primate: effects of rolipram and scopolamine on cognitive performance

Authors: T. WOLINSKY[1,2], C. CRUZ[3], I. HUBERT[3], M. LEMAIRE[1,2], *D. J. VIRLEY[1,2]
[1]Pharmacology-CNS, PORSOLT, BOULOGNE-BILLANCOURT, France; [2]PORSOLT RESEARCH CENTRE, Le Genest Saint Isle, France; [3]PORSOLT INC. USA, San Antonio, TX

Abstract: The Object Retrieval Test (ORT) or 'detour reaching test' in non-human primates (NHPs) is an established cognitive task thought to engage attention, response inhibition and planning (i.e. executive function). Importantly this test, involving prefrontal mechanisms, has been shown sensitive to both cognition-enhancing and cognition-impairing agents from distinct pharmacological classes.These findings suggest that the ORT in NHPs is relevant for assessing the pharmacological efficacy and safety of novel compounds on cognitive function thereby providing a useful translational bridge from rodent to human clinical studies.
The aim of the present study was to investigate the effects of rolipram and scopolamine using a simplified version of the ORT. 4 cynomolgus monkeys (*Macaca fascicularis*) were trained from their home cages to retrieve food rewards from a small clear box over the course of 24 trials per test session. Sessions containing 12 easy and 12 difficult trials were presented to each monkey in a balanced order. The level of task difficulty was determined by the positioning of the food

reward and the orientation of the box. The measure taken was the percent success at first-reach at each difficulty level. Rolipram (0.003 - 0.03 mg/kg i.m.) and scopolamine (0.010 - 0.040 mg/kg i.m.) were compared to saline (i.m.) on performance in the ORT for each monkey using a randomized within-subjects design. Using a 'best dose' analysis, rolipram was shown to significantly improve the percentage of accuracy of first-reaches during difficult trials in each of the 4 monkeys, whereas a clear impairment in performance was observed with scopolamine. These data suggest that our version of the test in a small number of monkeys together with a 'best dose' analysis to control for individual differences in response to specific doses provides a sensitive evaluation of the potential efficacy and safety of new chemical entities (NCEs) on cognition. This simple test of executive function should therefore have utility in guiding dose-prediction of NCEs for clinical assessment, with respect to neuropsychiatric disorders such as Alzheimer's disease, Parkinson's disease, Huntington's disease and Schizophrenia.

Title: Extracellular levels of BDNF in the hippocampus measured with microdialysis, change differentially during and after place and response learning.

Authors: *D. L. KOROL[1], P. E. GOLD[1], C. J. SCAVUZZO[2]
[1]Dept. of Biol., Syracuse Univ., Syracuse, NY; [2]Neurosci. Program, Univ. of Illinois, Urbana-Champaign, IL

Abstract: The role of brain-derived neurotrophic factor (BDNF) in neural plasticity, learning, and memory has been well established by many approaches including the delivery of antagonists and agonists, genetic manipulations, and analysis of tissue levels of the protein, its mRNA, and activation of downstream targets. To study BDNF functions across multiple memory systems, we previously examined tissue levels of mature BDNF (mBDNF) after rats were tested on a hippocampus-sensitive working memory task or on a striatum-sensitive response learning task.

The results showed that mBDNF levels increased in the hippocampus or striatum in a task-dependent manner. To test more directly the role for endogenous BDNF release in modulating learning and memory processing in these brain regions, we used in vivo microdialysis methods in the current study to measure changes in the concentration of mBDNF in the extracellular fluid (ECF) of the hippocampus, while rats were trained on a hippocampus-sensitive place task or a striatum-sensitive response task. Both tasks were conducted on the same 4-arm radial maze using food reward. The microdialysate was collected into micropipette tips (0.5 µl / min, 90 min samples) and diluted with sample buffer prior to analysis with ELISAs to determine BDNF concentration. The results indicate that ECF concentrations of hippocampal mBDNF increase from baseline during place training and continue to increase during the 90 min following training. In contrast, ECF mBDNF in the hippocampus falls below baseline and continues to decrease during the 90 min after response training. Because we interpret changes in ECF BDNF to reflect release of the protein, these data show that extracellular levels of mBDNF can be measured in awake, behaving animals and that mBDNF release is sensitive to cognitive demands. Moreover, the striking dissociation in the dynamics of extracellular hippocampal BDNF after place and response training suggests that brain site-specific patterns in BDNF release may reflect the cognitive strategies engaged by training in different tasks.

Title: Engagement in a spatial working memory task enhances subsequent place and response learning through BDNF signaling

Authors: *C. J. SCAVUZZO[1], D. L. KOROL[2], P. E. GOLD[2]
[1]Neurosci Program, Univ. of Illinois at Chicago, Champaign, IL; [2]Dept. of Biol., Syracuse Univ., Syracuse, NY

Abstract: This study examines a possible mechanism through which learning can be enhanced by prior experience. Rats were tested on a spontaneous alternation (SA) task using spatial

working memory immediately, 1 hr, or 24 hrs prior to learning a hippocampus-sensitive place task or a striatum-sensitive response task. Place and response learning were both assessed in a 4-arm maze for food reward. SA testing immediately and 1 hr, but not 24 hr, prior to training enhanced learning in both place and response versions of the maze. Previously we showed that improvements in place and response learning following physical activity relied on BDNF signaling during learning; blockade of TrkB receptors just prior to place and response testing attenuated improvements seen after three weeks of voluntary exercise. Because mature BDNF (mBDNF) release and signaling have been implicated in learning and memory, we tested whether, like physical activity, the cognitive activity induced by SA testing primes later place and response learning through BDNF-dependent events. First, rats were sacrificed immediately, 1 hr, and 24 hrs following SA testing to measure whole tissue concentrations of mBDNF in the hippocampus and striatum using ELISAs. Increased concentrations were detected in the hippocampus within 1 hr after SA, returning to baseline within 24 hrs. Striatal mBDNF concentrations increased at 1 hr after SA testing, increasing further at 24 hrs. Second, the importance of the changes in BDNF signaling to learning was examined using an inhibitor of the TrkB receptor, K252a. Rats trained on the place and response tasks 1 hr after SA testing received injections of K252a or vehicle into hippocampus and striatum, respectively, 30 min after SA testing, i.e. 30 min prior to place or response training. K252a infusions attenuated enhancements in place and response learning produced by prior SA testing. Blockade of TrkB signaling in rats without prior SA training did not impair performance. These results showing increased BDNF expression and attenuation of learning enhancements by K252a after cognitive activity are analogous to those seen when place and response learning are enhanced by prior physical exercise, suggesting common mechanisms to the effects on learning from both cognitive and physical activity.

Title: The effects of exercise on learning and hippocampal succinate dehydrogenase histochemistry: Sex differences and the interaction of estradiol

Authors: *K. L. MITTERLING[1], K. ANDERSON[2], D. L. KOROL[1]
[1]Dept. of Biol., Syracuse Univ., Syracuse, NY; [2]Psychology Dept, Univ. Illinois Urbana-Champaign, CHAMPAIGN, IL

Abstract: Epidemiological studies show that exercise and estrogen treatment enhance learning during healthy aging. Both treatments may also slow age-related memory decline or the progression of neurodegenerative diseases. Interventions started in young adulthood may confer even greater protection in old age and estrogen therapy may be more effective in women that are fit. Physical activity and exposure to estrogens can modulate brain metabolism, a possible shared mechanism for the neuroprotective effects of these treatments. Male and female young adult Long-Evans rats were trained on a hippocampus-sensitive spatial learning task following three weeks of voluntary running wheel access or sedentary housing in standard cages. Males were left gonadally intact while females were ovariectomized one week prior to separation into exercise (EX) or sedentary (SED) groups. Females received subcutaneous injections of 17β-estradiol benzoate (45 μg/kg) or sesame oil 48 and 24 hours prior to testing. Immediately after testing, rats were euthanized and brains harvested for hippocampal succinate dehydrogenase (SDH) histochemistry. Exercise significantly enhanced place learning in males compared to male sedentary controls. In females, the group that received EX+estradiol had enhanced learning relative to EX+oil, SED+oil, and SED+estradiol groups; learning in the latter three groups did not differ from each other. The finding that enhanced learning was evident only in the combined EX+estradiol groups suggests a synergistic effect between the treatments. In the female exercise conditions, estradiol enhanced total distance run in the 48 hours prior to testing compared to the EX+oil group. It is possible that the increase in physical activity contributed to the enhanced learning in this group. Unlike previous studies using Sprague-Dawley rats, estradiol alone failed to enhance place learning in Long-Evans females. The lack of enhancement by estradiol in sedentary females may be due to strain differences in estradiol sensitivity or may have been obscured because many sedentary rats failed to reach criterion within the 75 trial maximum; this ceiling effect may have precluded the ability to detect differences in criterion performance. After maze training, prior exercise significantly increased SDH staining density in the hippocampus in males vs their sedentary controls but did not significantly change SDH staining density in any female groups. Thus, while increased SDH expression may contribute to the ability of exercise to enhance place learning in males, a different cellular or metabolic pathway in females appears to contribute to the enhanced learning after EX+estradiol.

Title: A role for astrocytes in metamodulation of memory: Working memory and hippocampal extracellular lactate levels vary based on prior training

Authors: *P. E. GOLD[1], L. A. NEWMAN[1,2], C. J. SCAVUZZO[3], D. L. KOROL[1]
[1]Syracuse Univ., Syracuse, NY; [2]Psychology, [3]Neurosci. Program, Univ. of Illinois at Urbana-Champaign, Urbana-Champaign, IL

Abstract: Astrocytic glycogen provides an energy reserve that can supplement total energy available to neurons. Particularly during times of high demand such as during memory processing, astrocytes provide energy by breaking down glycogen to lactate and then supplying the lactate to neurons. Recent findings suggest that lactate is an important modulator of memory processing and show that extracellular (ECF) lactate levels increase selectively in brain regions engaged during learning and memory. Moreover, experience-dependent changes in glycogen stores are task specific: training on a hippocampus-sensitive spatial task can lead to long-lasting increases (>30 days) in glycogen content in the hippocampus while training on a striatum-sensitive response task leads instead to similar increases in glycogen content in the striatum. The present experiment was designed to determine whether these changes in glycogen resources are functionally significant. Rats were trained for food reward on either a place or response version of a 4-arm radial maze; controls underwent the same food restriction schedule but were not trained. After training, ad libitum access to food was returned for 28 days. At that time, rats were tested for spatial working memory on an unrewarded spontaneous alternation task. During alternation testing, ECF levels of lactate in the dorsal hippocampus were measured in 1-sec intervals using biosensor probes. Rats that had received prior place training had higher alternation scores on the spatial working memory task and had higher lactate release during alternation testing than did rats that had received prior response training. Second-by-second analyses of hippocampal lactate during alternation testing revealed significantly greater increases in lactate after completion of an alternation in previously place-trained rats as compared to response-trained rats. These findings reveal a form of metamodulation in which prior experience

primes subsequent memory in a task-specific manner with concomitant potentiation of energy reserves in specific brain regions. Thus, long-lasting changes in astrocytic glycogen reserves and lactate provision to neurons may play a substantial role in modulation and metamodulation of memory. Importantly, the response of ECF lactate levels to a working memory task is differentially affected by an experience at least 28 days before, in a manner consistent with the long-lasting changes in glycogen levels we have seen previously. Moreover, the present findings indicate that both long- and short-term changes in ECF levels of lactate are significantly related to past and current experience, respectively.

Title: Site- and task-specific ERK activation following genistein treatment corresponds to temporal aspects of learning

Authors: *S. L. PISANI[1], V. E. JUNG[2], D. L. KOROL[3]
[1]Neurosci. Program, [2]Sch. of Mol. and Cell. Biol., Univ. of Illinois at Urbana-Champaign, Champaign, IL; [3]Dept. of Biol., Syracuse Univ., Syracuse, NY

Abstract: The hippocampus and striatum undergo specific changes in cell signaling, gene transcription, and partitioning of metabolic substrates following place and response learning respectively. We previously found that oral treatments of genistein, a botanical estrogen found in soy, to young ovariectomized rats mimics estradiol-induced shifts in learning. Estrogens enhanced hippocampus-sensitive place learning but impaired striatum-sensitive response learning. Because local signaling via ERK plays an important role in estrogenic enhancement of hippocampal-sensitive memory tasks, we examined whether changes in ERK activation in hippocampus and striatum align with the magnitude and direction of shifts in place and response learning. Using quantitative Western blot analysis, ERK activation was measured in the

hippocampi and striata of rats trained on place or response learning tasks with or without genistein treatment. Simple increases and decreases in ERK activation in hippocampus and striatum following genistein were not observed. However, hippocampus to striatum (H:S) ratios of ERK activation corresponded to several features of learning. Placed-trained rats had approximately 2-fold higher H:S ratios of ERK activation than did response-trained rats, representing greater contribution of the neural structure critical for each respective task. Interestingly, in rats from the highest-performing treatment groups in each task, namely genistein-treated rats on the place task and vehicle-treated rats on the response task, faster task acquisition was associated with lower H:S ERK activation. We hypothesize that this greater striatal, or lower hippocampal, contribution represents a shift to habit/procedural memory through the over-training of rats that acquired the tasks quickly. In rats that acquired the tasks more slowly, i.e. the vehicle-treated rats on the place task and the genistein-treated rats on the response task, H:S ERK activation was correlated with the total duration of training. Specifically, rats with the slowest learning had the highest H:S ratios. Thus, the hippocampus appears to be engaged during early phases of acquisition of both place and response tasks, while the striatum dominates later in training after substantial learning. These results suggest a dynamic temporal relationship, rather than strictly competition or independence, between these neural systems in the acquisition and performance of different types of learning.

Title: Targeted deletion of ERK5 MAP Kinase in adult neurogenic regions attenuates hippocampal adult neurogenesis and hippocampus-dependent memory formation

Authors: *Y.-W. PAN[1], H. SAKAGAMI[2], M. G. GARELICK[1], G. C. K. CHAN[1], C. T. KUO[3], X. WANG[4], C. TOURNIER[4], D. R. STORM[1], Z. XIA[1]
[1]Univ. of Washington, Seattle, WA; [2]Kitasato Univ. Sch. of Med., Sagamihara, Japan; [3]Duke Univ. Med. Ctr., Durham, NC; [4]Univ. of Manchester, Manchester, United Kingdom

Abstract: Recent studies have led to the exciting idea that newly generated neurons in the adult dentate gyrus of the hippocampus may play a role in hippocampus-dependent memory formation. However, signaling mechanisms that regulate adult hippocampal neurogenesis are not well defined. Here we report that ERK5, a MAP kinase, is selectively expressed in the two neurogenic regions of the adult mouse brain. This unique pattern of expression distinguishes ERK5 from other signaling molecules implicated in adult neurogenesis, such as Wnt, PI3K-Akt and BDNF, which are more widely expressed in the brain. It also suggests that ERK5 may be critical in regulating adult neurogenesis. Indeed, shRNA knockdown of ERK5 in cultured aNPCs or conditional deletion of the ERK5 gene specifically in the neurogenic regions of the adult mouse brain reduces neurogenesis *in vitro* and *in vivo*, respectively. By contrast, ectopic activation of endogenous ERK5 signaling via expression of caMEK5 promotes neurogenesis in cultured aNPCs as well as in the dentate gyrus of mouse brains. These data suggest that ERK5 signaling is an important regulator of adult neurogenesis in SGZ cells *in vitro* and *in vivo.* Importantly, targeted deletion of ERK5 specifically in neural progenitors of the adult mouse brain caused deficits in the more challenging forms of hippocampus-dependent learning and memory including contextual fear when a weaker foot shock was administered. Conditional ERK5 KO mice are deficient in fear extinction and reversal water maze training and spatial memory, suggesting that ERK5 and ERK5-mediated adult neurogenesis is important for those forms of learning that require active forgetting of a prior memory. Furthermore, our data suggest a critical role for ERK5 and ERK5-mediated adult neurogenesis in pattern separation, a form of dentate gyrus-dependent learning and memory. Finally, conditional ERK5 KO mice have no remote memory in the passive avoidance test, suggesting for the first time a pivotal role for adult hippocampal neurogenesis in the maintenance of long term memory. Together, our results implicate ERK5 as a novel signaling molecule regulating adult neurogenesis and provide strong evidence that adult neurogenesis is critical for hippocampus-dependent memory formation and for the maintenance of long-term memory.

Title: Basolateral amygdala stimulation produces heterosynaptic suppression of inputs from other temporal cortical structures in the prefrontal cortex

Authors: *H. A. TEJEDA[1], T. SHIPPENBERG[2], P. O'DONNELL[3]
[1]Integrative Neurosci. Section, Nida-irp/University of Maryland, Baltimore, BALTIMORE, MD; [2]Natl. Inst. on Drug Abuse, Baltimore, MD; [3]Univ. of Maryland, Baltimore, Baltimore, MD

Abstract: The prefrontal cortex (PFC) is critical for executive control of behavior, behavioral flexibility, and working memory. These functions are dependent on highly interconnected circuits that include limbic substrates, such as the amygdala and hippocampus, as well as primary and associative cortices. Afferents arriving from the basolateral amygdala (BLA) likely provide information related to emotional states and may adjust PFC function. It is conceivable that strong amygdala activation reduces PFC synaptic responses to other afferents. Here, we examined the interactions between BLA inputs and those from other temporal cortical nuclei including the ventral hippocampus and the amygdalopiriform transition area (APiri), an associative cortical structure, using in-vivo intracellular recordings in anesthetized rats. Using sharp microelectrodes, medial PFC (mPFC) neurons were recorded intracellularly, and synaptic responses were generated by electrical stimulation of the BLA and fimbria (the fiber bundle carrying hippocampal projections to the PFC) or APiri. To determine whether BLA train stimulation attenuated hippocampal or APiri-evoked responses in the mPFC, a baseline test pulse (S1) was applied to the fimbria or APiri followed by conditioning burst stimulation of the BLA (10 pulses; 10, 20, or 50 Hz) 500 ms later. A test synaptic response (S2) was evoked at varying delays (50, 100, 150, 300, or 500 ms) after the last BLA pulse in the train. BLA burst stimulation attenuated fimbria- and APiri-S2-evoked EPSP amplitudes in a time- and frequency-dependent manner, with S2 responses at short delays being inhibited more robustly than those at longer delays. These effects were also observed using optical stimulation of the fimbria in rats expressing a light-sensitive cation channel in ventral hippocampal neurons. This effect is activity-dependent as single pulse BLA stimulation is without effect on fimbria- or APiri-evoked S2 responses at all delays. Fimbria and APiri train stimulation did not alter BLA-evoked responses, suggesting that heterosynaptic suppression of temporal cortical inputs is unidirectional and only produced by activation of the BLA-mPFC pathway. A BLA-evoked heterosynaptic suppression of other temporal cortical inputs could be critical for the selection of the appropriate behavioral response to fear-inducing or conditioned stimuli that would activate the amygdala. The mechanisms involved in this interaction remain to be discovered.

Title: Functional neuroanatomy of rat presubiculum

Authors: J. SIMONNET, E. EUGÈNE, I. COHEN, R. MILES, *D. FRICKER
CHU Pitié-Salpêtrière, CRICM, Paris, France

Abstract: The presubiculum, at the transition from hippocampus to cortex, is a key area for spatial information coding. We used patch clamp recordings from horizontal slices of rat (p21-35) hippocampus to establish the first detailed neuroanatomical description of this 6-layered cortex. Neurons were filled with biocytin for post hoc analysis. Principal neurons were classified on the basis of 15 anatomical and 14 electrophysiological parameters. Neuronal subpopulations were defined using Ward's unsupervised clustering from 58 completely characterized presubicular cells.
We found three main cell types that followed the laminar distribution of somata. Cluster 1 contained principal neurons in layers II and III (n = 24), small pyramidal shaped regular spiking cells. This group was homogeneous, with the most negative resting membrane potential (RMP, -77.5 ± 0.8 mV), compared to all other groups. Dendrites were confined to superficial layers only. Cluster 2 contained intrinsic bursting pyramidal cells (n = 6) in layer IV, previously not described. These low resistance neurons had a RMP of -62.1 ± 1.4 mV, close to firing threshold. Bursting neurons had a high sag index, 1.23 ± 0.03, suppressed by ZD7288 (20 µM). Cluster 3 contained regular spiking neurons of layers V and VI cells with large action potential widths. Two subclusters rapidly emerged: 3.1 with diverse shapes, including pyramidal, multiform and inverted pyramidal cells (n = 17); 3.2 with high resistance pyramids, more excitable than the other clusters (n = 11).
Some presubicular cells provide maintained head direction signals in vivo. Similarly, firing frequency adapted very little during maintained depolarization in vitro, for most regular spiking presubicular cells. A late adaptation index was calculated for 20 Hz maintained firing over 800 ms, showing a mean diminution of firing frequency of less than 10 %.
Thus, the presubiculum contains the cellular elements of cortical circuits. Regular spiking

neurons in superficial and deep layers possess an unusually weak firing adaptation, while layer IV neurons are intrinsically bursting.

Abstract: Interactions between the hippocampal formation (HF) and the parahippocampal region (PHR) contribute to encoding, consolidation and retrieval of declarative memories. Knowledge of the neuroanatomical connections of the HF and PHR is a prerequisite to understand how these neural interactions affect for example memory processing. To provide this knowledge in a comprehensive and transparent way, we constructed a connectome in which the three-dimensional organization of the projection patterns between and within the 14 sub-regions of the HF and PHR are displayed in an interactive visualization. This connectome has several unique

features. First, the three-dimensional topographical detail is as high as current knowledge permits. Second, the connectome is interactive, i.e. connections can be switched on and off. Third, through decades of neuroanatomical research, the nomenclature has changed significantly. This connectome provides a translation of one nomenclatures into another via a 'Rosetta Stone'. The 2012 update of this project introduces a new project website with an online interactive literature search tool, advanced PubMed queries aimed at finding the right connectivity literature and a more detailed description of the 14 sub-regions incorporated in the interactive connectome. The search tool allows one to interactively search for literature describing connections between a set of brain regions that are part of the connectome. In addition, access to advanced PubMed search queries is provided to help researchers create more effective searches. The expanded section on hippocampal anatomy allows both students and experienced researchers to experience new things about hippocampal anatomy. The poster will be accompanied with a live demonstration of the new online resources.

Title: Brainstem afferents to the hippocampal formation: Comparative immunohistochemical study in the Macaca fascicularis monkey

Abstract: The synaptic plasticity of the Hippocampal Formation (HF, which includes the dentate gyrus -DG-, CA3, CA2, CA1, subiculum, pre-parasubiculum and the entorhinal cortex -EC) is strongly influenced by neurotransmiters (presumably Dopaminergic -DA, Ventral Tegmental

Area-VTA; Noradrenergic -NA, Locus Coeruleus-LC and Serotoninergic -5-HT, Raphe Nuclei-RN, respectively), (Otmakhova and Lisman, 1996; Katsuki et al., 1997), although the anatomical basis of the chemical modulation of memory in the HF is far from being understood.
The neuroanatomical connections between the brainstem and in the HF in the nonhuman primate are still unclear. Previous tracer studies showed retrogradely labeled neurons in the brainstem areas including the VTA, LC and RN, after deposits in the hippocampus (Amaral and Cowan, 1980), as well as in the EC (Insausti et al., 1987). In order to characterize the neurochemical nature of those projections, as well as their topographic and laminar differences, we studied comparatively the distribution on those substances in the HF using immunohistochemical techniques.
Immunohistochemistry for each DA (Tyrosine Hydroxylase, TH), NA (Dopamine Beta Hydroxylase -DBH-, and 5-HT) as well as double-immunohistochemical techniques using Alexa 488 (5-HT detection) and Alexa 568 (TH or DBH labeling) disclosed that:
•The polymorphic layer of the DG had fibers with the three neurotransmitters, whereas the molecular layer showed only TH and 5-HT immunolabeling, without double-stained processes.
•The pyramidal layer of CA3 showed denser 5-HT fiber labeling than TH; CA1 showed only scattered TH and 5-HT fibers, without double labeling profiles.
•The subiculum and presubiculum showed fibers immunoreactive for TH, SER and BHD in the molecular layer. No double-labeled TH-5HT or DBH-5HT fibers were seen.
•The superficial layers of the rostral EC (I and II) displayed TH- or 5-HT-labelled processes, while the most lateral subdivisions of EC (ELR/ELc) had TH- or DBH-positive fibers; they did not show co-localization.
The preferential location of these positive fibers in ELR/ELc is significant, as this portion of the EC receives abundant unimodal and polymodal sensory input and innervates the body and tail of the hippocampus, and therefore it might be an important step for the monoaminergic modulation memory consolidation. Our preliminary anatomical results suggest that the HF function may be modulated independently by monoaminergic neurotransmitters.

Title: A tract-tracing study of entorhinal cortex afferents to the dorsolateral frontal cortex in the nonhuman primate (Macaca fascicularis).

Authors: *M. LEGIDOS GARCIA[1], M. M. ARROYO-JIMÉNEZ[1], E. ARTACHO-PERULA[1], S. CEBADA-SÁNCHEZ[1], J. GONZALEZ-FUENTES[1], D. HERNÁNDEZ-MOMBIELA[1], M. IÑIGUEZ DE ONZOÑO[1], M. J. Abstract: Retrograde tracing studies in the nonhuman primate have shown that the dorsolateral prefrontal cortex (DLPFC) presents a paucity of afferents to the entorhinal cortex (EC, Insausti et al., 1987). Further experiments with anterograde tracers (Insausti et al., 2005) confirmed this fact. In contrast, the rodent EC provides a broad innervation of all frontal cortex (Swanson and Köhler, 1986; Herrero et al., 1987). Given the importance of the DLPFC in different cognitive and behavioural functions such as encoding and retrieval of declarative memory, it is striking that the nonhuman primate DLPFC is scarcely connected by direct projections to the EC, the main gateway to the hippocampus. In order to clarify whether the EC projects to the DLPFC in a reciprocal fashion to the same areas it gets afferents from, or whether it is able to influence to a higher degree the DLPFC, we studied the prefrontal afferents to the EC by neuroanatomical anterograde tracing techniques.
We analyzed nine cases of Macaca fascicularis with byotinilated Dextran Amine (BDA, mw 10,000) deposits in various portions along the medio-lateral and rostro-caudal axes of the EC. A magnetic resonance (MR) examination to localize the stereotaxic coordinates of the injection site was performed in all the animals. After 2 weeks survival, animals were perfused through the heart with 4% paraformaldehyde. Other cases were injected with 3H-aminoacids and PHA-L resulting in deposits in various portions along the EC.
The main finding is that, relative to other prefrontal regions as the orbitofrontal (OFC) and medial frontal (MPFC) cortices, the EC afferents were overall, negligible. BDA deposits in the intermediate portion of the EC resulted in the densest projection, which was located in Areas 9 and 8, in reciprocity with retrograde studies. Other cases, with deposits placed at other locations of the EC, showed only scattered fibers in the white matter, some of the which, seemed to reach layer VI. The distribution of labeled fibers after mid entorhinal cortex portions showed labeled fibers in layers I and VI of Areas 9 and 8. The weakest labeling resulted after deposits in caudal portions of the EC, suggesting that little or no direct interplay between this portion (which projects to the body and tail of the hippocampus), and the dorsolateral prefrontal cortex is present in the nonhuman primate.

Our results suggest that the hippocampal output to the DLPFC is not direct, but mediated by the relay of other prefrontal regions as MPFC and OFC.
The functional significance of this particular pattern of connectivity between the hippocampal formation and the dorsolateral prefrontal cortex warrants further investigation.

Title: Connections between the medial temporal lobe and the lateral mediodorsal thalamic nucleus in macaque monkey

Authors: *V. L. MCCOY[1], D. S. MELCHITZKY[1,2], S. L. ERICKSON[2], D. A. LEWIS[2,3]
[1]Biol., Mercyhurst Univ., Erie, PA; [2]Psychiatry, [3]Neurosci., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The mediodorsal thalamic nucleus (MD) is the principal source of subcortical input to the prefrontal cortex (PFC) with different domains within MD targeting particular prefrontal cortical areas. The medial temporal lobe (MTL) is comprised of the hippocampal formation and the perirhinal and parahippocampal cortices and plays a fundamental role in memory functioning. Understanding the topography of the projections from the MTL to different domains within MD will help determine the specific types of information available to each MD domain and subsequently to the PFC. In this study, injections of the retrograde tracer cholera toxin b subunit (CtB) were made into discrete locations of the lateral portion of the MD in four macaque monkeys. Two of the animals had CtB injections in both hemispheres, resulting in six injections sites for analysis. Bilateral coronal sections through the MTL in each animal were processed immunocytochemically to visualize the CtB. Drawings of CtB- immunoreactive cells in the MTL were made from sections spaced 50 microns apart using a camera lucida drawing tube attached to a microscope, and Nissl- and Geimsa- stained sections were used to delineate the borders between the various areas of the MTL. Each injection site had a unique distribution of

retrogradely-labeled cells throughout the MTL and the proportion of labeled neurons in each component of the MTL differed greatly across injection sites. For example, an injection in the ventrolateral MD resulted in a large proportion of labeled neurons in the presubiculum (77%) with very few cells in the CA fields (1.3%). In contrast, the largest proportion of labeled cells following an injection in the caudoventrolateral MD was found in the CA fields (61%). Initial inspection of an anterodorsal injection site suggested a more evenly distributed pattern of labeling between the CA fields and subicular areas. Differences in the proportion of labeled neurons in both the perirhinal and parahippocampal cortices were also seen across the injection sites, although none of these cortical areas contained the majority of labeled neurons from any injection site. These findings suggest that individual locales within the lateral MD receive topographically distinct projections from the MTL, implying that a different complement of information from the MTL is relayed to specific domains of MD.

Title: Neural mechanisms mediating the use of imagery and inferential reasoning by rats in ambiguous situations.

Authors: *C. D. FAST, M. M. FLESHER, S. R. STERLACE, N. A. NOCERA, M. S. FANSELOW, A. P. BLAISDELL
Univ. of California - Los Angeles, LOS ANGELES, CA

Abstract: Fast & Blaisdell (2011) demonstrated that prior learning influenced how rats behave in ambiguous situations. Rats that had learned a challenging, non-linear negative patterning task (where two cues are reinforced when presented individually but not when they are presented in compound) responded significantly differently when one cue was occluded from view (ambiguously absent) compared to when it was explicitly absent. Specifically, rats behaved as if they were unable to determine if an ambiguous trial constituted an elemental or compound trial

from training by emitting significantly fewer instrumental lever presses when the cue was ambiguous compared to when it was explicitly absent - suggesting an image of the ambiguous cue was active. Rats that had learned a simple linear positive patterning discrimination (individual presentations of each cue are not reinforced while the compound presentation is), on the other hand, did not respond differently in the two test situations. Interestingly, rats trained on a positive patterning task do show sensitivity to the ambiguous test situation if they had also been trained on a negative patterning task. After learning both discriminations, rats responded significantly more during ambiguous test trials with cues that had previously served in the positive patterning discrimination compared to test trials when the cue was explicitly absent. These results suggest that the more complex task of negative patterning engaged representational processing capacities necessary for sensitivity to ambiguity that were otherwise not engaged by positive patterning. Acetylcholine is known to regulate cognitive tasks through its impact on both the processes of attention and plasticity (Reber, Luechinger, Boesinger, & Henke, 2012; Zeithamova, Schlichting, & Preston, 2012). Therefore, as an initial step toward identifying the brain mechanisms responsible for this behavioral sensitivity to ambiguity, we tested subjects after administering the muscurinic cholinergic antagonist scopolamine. In a follow-up experiment, we specifically investigated the role of the hippocampus through temporary inactivation. The results have interesting implications for representational processes and the underlying neural mechanisms engaged in problem solving.

Title: Enzymatic analysis of glutathione reductase in wistar rats with moderate traumatic brain injury: A dosage dependent approach

Authors: *J. T. JOHNSON[1,1], Z. P. SELLERS[1], T. T. REED[1], P. G. SULLIVAN[2], A. SEBASTIAN[2]
[1]Chem., Eastern Kentucky Univ., Richmond, KY; [2]Univ. of Kentucky, Lexington, KY

Abstract: Imbalances in the production of reactive oxygen species (ROS) and native antioxidant mechanisms result in oxidative stress(1). Glutathione is a key antioxidant in the neutralization of the ROS, and it is hypothesized that when γ-glutamylcysteine ethyl ester (GCEE), a glutathione mimetic, is administered a decrease in oxidative stress will be shown in the moderate traumatic brain injury rat model. Glutathione reductase is responsible for reducing oxidized glutathione to allow further protection against oxidative stress via the oxidation of β-nicotinamide adenine dinucleotide phosphate. Reduced glutathione can initiate ROS reduction to protect against oxidative stress. GCEE was administered using a dosage dependent approach, and the significance of each dose was determined by examining the activity of glutathione reductase in brain samples treated with GCEE and brain samples treated with saline at time intervals of either 30 or 60 minutes post injury. Each sample was analyzed using a glutathione reductase assay modified from Sigma Aldrich (St. Louis, Missouri, USA). Enzyme kinetics analysis for the assay was examined using spectrometric analysis. Brain samples treated with a dosage of 150 mg/kg of body weight of GCEE yielded an increase in the activity of glutathione reductase compared to those treated with saline, indicating the presence of increased levels of reduced glutathione. The increased activity correlates with elevated antioxidant capacity. This lowers overall oxidative stress making this a potential post injury therapeutic strategy for moderate traumatic brain injury. Ongoing future research is being conducted to determine how GCEE affects other key enzymes such as glutathione peroxidase, glutathione S-transferase, and glucose-6-phosphate dehydrogenase.

Title: 3-nitrotyrosine as an oxidative stress indicator in wistar rats involving moderate traumatic brain injuries for proteomic analysis

Authors: *M. T. HENDERSON, J. JOHNSON, J. VANZANT, Z. SELLERS, T. REED
Chem., Eastern Kentucky Univ., Richmond, KY

Abstract: 3-Nitrotyrosine(3-NT) is one of the most frequently observed byproducts from reactive nitrogen species (RNS) reacting with proteins. As a biomarker of nitrosative stress, elevated levels of 3-NT signify the presence of oxidative stress and decreased levels of antioxidant enzymes. Traumatic brain injury (TBI) is profoundly related to oxidative stress, which has been indicated as a mechanism of secondary neuronal injury in TBI that can ultimately result in numerous related neurological maladies. Therefore, 3-NT can be utilized as an *in vivo* marker of oxidative nitric oxide damage following TBI. By using a moderate traumatic brain injury model with Wistar rats, it is hypothesized that the role of 3-NT formation as an intermediate will predict the involvement of protein nitration and oxidative stress in the brain. In this experiment, the levels of 3-nitrotyrosine were significantly elevated in TBI injured, saline treated rats compared to those who sustained an injury and were treated with the glutathione mimetic, GCEE. Determining the existence of elevated 3-NT levels provides insight into the relationship between protein nitration and oxidative stress which can determine the pathogenesis and progression of specific neurological diseases.

Title: Gamma-glutamylcysteine ethyl ester as a post therapeutic treatment for moderate traumatic brain injury in rat: Insights into glutathione elevation

Authors: *Z. SELLERS, T. T. REED
Chem., Eastern Kentucky Univ., Richmond, KY

Abstract: Glutathione is a multifunctional tripeptide found in millimolar concentrations in the human brain. As a detoxifying agent, glutathione plays an integral role in maintaining cellular

integrity, serving as both an antioxidant and a conjugant for exporting toxic species (*1*). Traumatic brain injury (TBI) causes initial tissue damage in the brain, but also leads to secondary injuries mediated in large part by free radicals (*2*). Thus, glutathione requirements in the brain are greatly increased following TBI. Gamma-glutamylcysteine ethyl ester (GCEE) is an analog to a natural glutathione precursor that has been shown to increase intracellular glutathione levels in the human brain (*3*). Using a cortical contusion model for moderate traumatic brain injury in male Wistar rats, we are measuring the effect of post-TBI GCEE treatment on oxidative stress parameters in rat brain. We hypothesize that GCEE treatment will significantly increase overall glutathione concentration and the ratio of reduced glutathione to oxidized glutathione in the brains of male Wistar rats following moderate TBI. To test this hypothesis, the brain samples are first standardized by measuring their protein concentrations photometrically via the bicinchoninic acid assay method. Kinetic assays are then performed on each sample to test for reduced glutathione, oxidized glutathione, and total glutathione concentrations. These assays employ the reduction of 5,5'-dithiobis-(2-nitrobenzoic acid) via the oxidation of reduced glutathione, which is measured photometrically at 412 nm. For measuring total glutathione levels, glutathione is recycled by glutathione reductase and reduced nicotinamide adenine dinucleotide phosphate during the assay. Oxidized glutathione is measured by first neutralizing reduced glutathione using 2-vinylpyridine, then assaying the sample in combination with the glutathione recycling method. By testing our rat models for glutathione elevation, we hope to offer insight into the development of post therapeutic treatment options for traumatic brain injury patients.

Title: N-methyl-d-aspartic acid receptor distribution in fear-conditioned, socially partnered and socially isolated Wistar rats

Authors: E. HUSAIN[1], J. DASILVA[1], Y. LEI[1], A. MORRISON[2], *S. M. TEJANI-BUTT[1]
[1]Philadelphia Col. Pharm, Univ. Sci. Philadelphia, Philadelphia, PA; [2]Dept. of Animal Biol., 2University of Pennsylvania Sch. of Vet. Med., Philadelphia, PA

Abstract: Resilience or vulnerability to stress involves both genetic and environmental factors. Compared to other out-bred rat strains, the Wistar (WIS) rat exhibited reduced freezing behavior to predator odor, suggesting that the WIS rat may be a more resilient strain. We had previously reported that cued fear-conditioning (CFC) increased freezing behavior in socially isolated WIS rats with little effect on sleep microarchitecture. While the freezing response to CFC was attenuated on Day 1 in socially partnered WIS rats, social partnering induced a fragmented rapid eye movement sleep pattern that was independent of CFC. Given that extensive connections between the limbic and forebrain regions are thought to regulate fear responses, the goals of the present study were to investigate the effects of CFC on N-methyl-D-aspartate (NMDA) receptors in socially isolated (CFC-SI) and socially partnered (CFC-SP) environments in WIS rats. The binding of [^{3}H] MK-801 to NMDA receptors was measured in the prefrontal cortex (PFC), basolateral amygdala (BLA), central amygdala (CeA), CA1/CA2, CA3, dentate gyrus (DG), ventral tegmental area (VTA), nucleus accumbens core (NAcc), nucleus accumbens shell (NAcsh), caudate putamen (CPU) and substantia nigra (SN). The results indicated that while CFC-SI rats exhibited decreased binding of [^{3}H] MK-801 to NMDA receptors in the PFC, BLA, CA1/CA2, DG, NAcc, VTA, CPU and SN as compared to control WIS rats, CFC-SP rats exhibited increased binding in the PFC, BLA, CeA, CA1/CA2, CA3, DG, NAcc, NAcsh, CPU and SN as compared to the CFC-SI group. It has been hypothesized that glutamatergic inputs to the amygdala from the PFC function to modulate fear output pathways via activation of inhibitory interneurons within the amygdalar microcircuitry. Decreased NMDA receptor densities in the PFC, BLA and hippocampus of CFC-SI rats may reflect a mechanism of receptor down-regulation in response to increased glutamatergic activation and inhibition of the amygdala, supporting our previous observations that CFC did not alter sleep in socially isolated WIS rats. In contrast, social partnering increased NMDA receptor density in the PFC, amygdala and hippocampus of CFC-SP rats. These results suggest that complex interactions between the PFC, amygdala and the hippocampus as well as several limbic regions are differentially involved in the modulation of freezing behavior and sleep disruptions in WIS rats.

Title: N-methyl-d-aspartic acid receptor distribition in fear-conditioned, socially partnered and socially isolated wistar-kyoto rats

Authors: *J. K. DASILVA[1], E. HUSAIN[2,1], Y. LEI[1], G. L. MANN[3], A. R. MORRISON[3], S. TEJANI-BUTT[1]
[1]Pharmaceut. Sci., Univ. of the Sci., Philadelphia, PA; [2]Applied Med. Sci., Univ. of Tabuk, Tabuk, Saudi Arabia; [3]Animal Biol., Univ. of Pennsylvania Sch. of Vet. Med., Philadelphia, PA

Abstract: Social environment has a profound effect on the susceptibility to developing stress-induced disorders. The Wistar-Kyoto (WKY) rat strain is known for its stress-sensitive phenotype. We have previously reported that socially partnered WKY rats exhibited a reduced effect on sleep-wake behavior in response to cued fear conditioning (CFC) compared to their socially isolated counterparts. Extensive connections between limbic regions and the forebrain are thought to regulate fear responses, and altered glutamatergic neurotransmission in these regions has been implicated in stress-induced psychiatric disorders. The goals of the present study were to investigate the effects of CFC on N-methyl-D-aspartate (NMDA) receptor binding in socially partnered (CFC-SP) and socially isolated (CFC-SI) WKY rats. The binding of [3H] MK-801 to NMDA receptors was measured in the prefrontal cortex (PFC), basolateral amygdala (BLA), central amygdala (CeA), CA1/CA2, CA3, dentate gyrus, ventral tegmental area, nucleus accumbens (NAc), caudate-putamen (CPU) and substantia nigra (SN). The results indicated that CFC in a socially isolated environment increased [3H] MK-801 binding in the PFC and SN, but CFC in a socially partnered environment increased binding in the BLA, CeA, and NAc. It has been hypothesized that glutamatergic projections from the PFC modulate fear expression by inhibiting amygdalar activity. Increased NMDA receptor density in the PFC of CFC-SI rats may reflect a mechanism of receptor up-regulation in response to decreased glutamatergic activation and disinhibition of the amygdala, supporting our previous observations that CFC-SI WKY rats exhibited increased freezing behavior and disrupted sleep. Furthermore, social partnering normalized PFC receptor density in CFC WKY rats and increased NMDA receptor density in the BLA and CeA, consistent with our previous observations of reduced freezing behavior and an absence of sleep disruption in these animals. No effect was observed in the hippocampal NMDA

receptor density of CFC-SP rats suggesting that the decreased behavioral response to conditioned fear may not involve NMDA receptor mediated mechanisms in the hippocampus. Thus, the attenuated conditioned fear response in socially partnered WKY rats may be occurring via the engagement of the PFC, amygdala and NAc but not the hippocampus or CPU.

Title: Juvenile social defeat alters fear extinction learning during adolescence and impairs social behavior into adulthood.

Authors: *L. A. FARNBAUCH, A. M. JASNOW
Psychology, Kent State Univ., Kent, OH

Abstract: Anxiety is important for health and survival, but can become excessive, as exemplified by Post Traumatic Stress Disorder (PTSD); arising after trauma and eventually leading to a host of maladaptive behaviors, causing memory disturbances and impairing decision making. Anxiety disorders can present early in life, during brain development, and can influence judgment and interfere with social relationships. Moreover, there is a very strong relationship between the level of childhood trauma and adult anxiety disorder symptoms in humans. In the current study, we used acute social defeat as an animal model of trauma and stress to investigate the effects of social stress on subsequent social behavior, anxiety-like behavior, as well as fear learning and extinction in adolescent and adult mice. Juvenile (PND 28±4) male C57Bl6/J mice were subjected to social defeat and tested 24 hours and thirty days later for social interaction. 24 hours after social interaction testing the mice were tested for anxiety-like behavior using an elevated-plus maze. One week or five weeks post-defeat we used a standard cued fear conditioning procedure to examine the effects of prior social defeat on the acquisition, expression and extinction of fear. Juvenile mice exhibited normal social interaction compared with non-defeated controls when tested with an age-matched CD1 stimulus mouse, but interacted less when tested with an adult CD1 mouse 24 hours after defeat. When these mice were tested as adults (30 days post defeat), defeated mice still exhibited significantly reduced social interaction compared with control mice. Mice defeated as juveniles displayed normal fear acquisition during

adolescence as well as in adulthood, but extinction learning was impaired during adolescence only. These effects were observed without apparent alterations in anxiety-like behavior. We demonstrate that acute social defeat during the juvenile period produces long-term, yet differential effects on social behavior and cued fear during adolescence versus adulthood.

Title: Sex differences in the generalization of contextual fear

Authors: *J. F. LYNCH, III, M. LATSKO, P. K. CULLEN, A. M. JASNOW, D. C. RICCIO
Psychology, Kent State Univ., Kent, OH

Abstract: There is a high prevalence of anxiety disorders among adults,and females are 60% more likely to suffer from an anxiety disorder than males. One hypothesis for these findings may be that females exhibit higher rates of fear generalization than males. It has been demonstrated that the generalization gradient for contextual cues flattens over time whereas retention of the learned response remains intact in male subjects.The current experiment was designed to investigate the possibility of sex differences in the generalization of contextual cues. 184 male and female Long-Evans rats were trained and tested in a passive avoidance procedure to examine sex differences in the forgetting of stimulus attributes, as inferred from flattening of the generalization gradients. Rats were tested at different retention intervals (1, 3, 5, or 7 days) in either the same context as training or in a significantly altered context. At 1 day, male and female rats displayed equivalent levels of reduced fear when tested in a novel context, as expected (i.e., the context shift effect). Males continued to express reduced fear in a novel context across all retention intervals, whereas females exhibited comparable levels of fear in either context after 3 days. Overall, females showed no significant differences in the expression of fear between contexts at the 3, 5, and 7 day retention intervals. These results demonstrate that the generalization gradient for contextual cues flattens at a faster rate in female rats. Current work in the lab is attempting to elucidate the role of estrogens in the forgetting of contextual cues.

Title: Cell-type specific optogenetic activation mediates fear inhibition in the basolateral amygdala

Authors: *A. M. JASNOW[1], D. EHRLICH[2], D. C. CHOI[2], M. E. BOWERS[2], D. G. RAINNIE[2], K. J. RESSLER[3,2]
[1]Dept. of Psychology, Kent State Univ., Kent, OH; [2]Psychiatry and Behavioral Sciences, Ctr. for Behavioral Neurosci., Emory Univ. Sch. of Med., Atlanta, GA; [3]Howard Hughes Med. Inst., Bethesda, MD

Abstract: Previous research identified distinct neuronal circuits within the basolateral amygdala (BLA) that differentially correlate with fear expression and inhibition. Here we examine if optogenetic activation of a cellular subpopulation within the BLA would differentially support fear conditioning vs. fear inhibition / extinction. Using transgenic mice, we demonstrated that a Thy1-channelrhodopsin-2 (Thy1-ChR2-EYFP) expressing subpopulation of BLA pyramidal neurons was activated by fear expression and extinction. Optogenetic stimulation of these neurons inhibited a subpopulation of medial central amygdala (CeM) neurons and shunted excitation from the lateral amygdala (LA). Brief activation of these neurons during training disrupted fear memory when tested 24 hr later. Furthermore, optogenetic activation during unreinforced stimulus exposure enhanced extinction retention, but not within-session extinction, and had no effect on fear expression, locomotion, or open-field behavior. Furthermore, optogenetic-induced enhanced extinction consolidation also inhibits renewal of fear. These data suggest that Thy1-ChR2 expressing BLA neurons provide an important molecular and pharmacological target for inhibiting fear and enhancing extinction in fear-related disorders.

Title: Impaired social interaction and fear extinction in a mouse social defeat model of PTSD.

Authors: *J. D. MEDURI, B. N. DULKA, A. M. JASNOW
Psychology, Kent State Universty, Kent, OH

Abstract: Posttraumatic stress disorder (PTSD) is an anxiety disorder that results after single or repeated exposure to a traumatic event. In humans, this disorder is associated with significant deficits in the ability to extinguish fear responses. Social stress is one of the most prevalent stressors experienced by many animal species. For instance, interpersonal violence is a significant contributor to the development of PTSD in humans. Several studies demonstrated that the experience of social defeat produces drastic and prolonged alterations in subsequent agonistic behavior. However, it is unclear how social stress modifies subsequent responses to other emotionally relevant stimuli. In the current study, we used acute social defeat as an animal model of trauma and stress to investigate the effects of social stress on subsequent social behavior, anxiety-like behavior, as well as fear learning and extinction. Mice were subjected to social defeat and tested 24 hours later for social interaction. 24 hours after the social interaction test, mice were tested for anxiety-like behavior using an elevated-plus maze. One week post-defeat we used a standard cued fear conditioning procedure to examine the effects of prior social defeat on the acquisition, expression and extinction of fear. Acute social defeat produced long-term effects on social behavior both 24 hours and 30 days post-defeat, with no apparent alterations in anxiety-like behavior. In addition, acute social defeat had no significant effect on the acquisition of fear conditioning but disrupted the within-session extinction and extinction retention. We demonstrate here that acute social defeat produces long-term changes in both social behavior and subsequent cued fear extinction. These data suggest that exposure to social stress may act to reorganize fear circuits resulting in prolonged alterations in subsequent emotional learning.

Title: The role of presynaptic inhibition in the generalization of context memory

Authors: *P. K. CULLEN, S. TRASK, B. DULKA, D. C. RICCIO, A. M. JASNOW
Psychology, Kent State Univ., Kent, OH

Abstract: Contextual fear conditioning involves pairing a novel context (conditioned stimulus) with several footshocks (unconditioned stimulus) that serve to condition fear to that context. Many studies have demonstrated that shifting contextual cues following context fear conditioning results in reduced freezing, (i.e., the context shift effect). At early time points rodents can discriminate between a training and novel context. However, these shifts in contextual cues become less disruptive as the retention interval between training and testing increases (context specificity is lost by 14 days post-training). In other words, the fear memory is no longer precise or context-specific, but has generalized to novel contexts. In an attempt to investigate potential mechanisms underlying the generalization of fear responses over time, we have identified presynaptic inhibition as playing a role in the precision of context memory. Specifically, we discovered that mice lacking a GABAB1 receptor subtype, GABAB1a, exhibit a loss of context discrimination compared to wild-type animals. Animals lacking GABAB1a receptors showed a significant, but not complete loss of context specificity 24 hours post-training. However, GABAB1a knock out mice exhibited a complete loss of context discrimination (i.e. generalization) by 5 days post-training. Our results indicate that presynaptic inhibition is required for the discrimination of context and identify GABAB1a receptors as a potential mechanism underlying context fear generalization. We are currently investigating the specific neural location that these receptors are required for context discrimination.

Title: Dopamine controls the precision of long-term fear memory

Authors: *C. A. LEPPLA, S. TRASK, A. M. JASNOW
Psychology, Kent State Univ., Kent, OH

Abstract: It is well established that the hippocampus plays an important role in the formation and consolidation of contextual memory, but the underlying biological mechanisms of retention and precision in this system are still not fully understood. Many studies have demonstrated that shifting contextual cues following context fear conditioning results in reduced freezing, (i.e., the context shift effect). At early time points rodents can discriminate between a training and novel context. However, these shifts in contextual cues become less disruptive as the retention interval between training and testing increases (context specificity is lost by 14 days post-training). In other words, the fear memory is no longer precise or context-specific, but has generalized to novel contexts. Rossato et al. (2009) demonstrated that a weak context memory persisted up to 14 days in rats after a 12-hour post-training hippocampal infusion of a D1 agonist was administered, whereas control animals lost the memory after 2 days. This study provided evidence that dopamine is required for the persistence of a context memory, but it is unclear if dopamine is involved in the maintenance of the precision of the memory. The current study explores the role of dopamine in regulating contextual memory precision in long-term memory. C57BL/6 mice were given bi-lateral infusions of a D1 agonist (SKF38393, 0.50μL 25μM) into the dorsal CA1 region of the hippocampus 12 hours after context fear training. Mice infused with SKF38393 exhibited greatly reduced context generalization when tested 14 days later in a novel context compared with vehicle controls. This suggests that dopamine not only plays an important role in regulating the persistence of contextual fear memory, but also the precision of those memories.

Title: Adult fear expression as a function of early life attachment and motherhood

Authors: *R. E. PERRY[1,2,3,4], R. M. SULLIVAN[1,2,3,4]
[1]Emotional Brain Inst., Nathan Kline Inst., New York, NY; [2]Child and Adolescent Psychiatry, NYU Sch. of Med., New York, NY; [3]NYU Child Study Ctr., NYU Langone Med. Ctr., New York, NY; [4]Neurosci. & Physiol., NYU Sackler Inst. for Grad. Biomed. Sci., New York, NY

Abstract: In a fearful situation, individuals can respond passively (i.e. freezing, risk assessment) or actively (i.e. fleeing, exploring, fighting), with fear expression being dependent on context and prior experience. Early life abuse and motherhood have been shown to alter later life fear expression, although the mechanisms by which early life experience and motherhood shape fear expression are not fully understood. Here we examine how infant abuse and motherhood program the adult to be primed for active fear expression.
Methods: Rat pups were reared with either a normal or abusive mother (PN8-12), and were permitted to reach adulthood and give birth. Fear expression in virgin controls and mothers (with and without pups), was assessed with two tests: 1) Naturally fearful odor presentation (predator odor) and 2) Learned fearful odor presentation (after odor-0.7mA shock conditioning). For both tests, we explored active and passive fear responses and maternal behavior.
Results: Early life abused and mother rats differed significantly from control rats in both tests. In the predator odor test, mothers and early life abused rats spent more time near the predator odor and less time hiding compared to virgin controls. Mothers and early life abused rats exhibited more active fear responses in both tests. In the learned fear cue test, mothers abused in infancy displayed decreased active fear responses compared to normally reared mothers.
Conclusion: Early life abuse and motherhood change fear expression from passive (freezing, risk assessment) to active (fleeing, and approaching danger) fear. These data suggest that both early life abuse from the caregiver and becoming a caregiver may alter the response selection process for fear expression.

Title: A blast from the past: How prior experience modulates transmission of fear

Authors: *A. CRUZ, M. A. MOITA
Champalimaud Neurosci. Programme, Lisboa, Portugal

Abstract: In natural populations social cues are often used to avoid danger. This transmission of information can account, in part, for the success of social species, as an animal does not need to experience the threat in order to avoid it.
Previous studies showed that prior experience with shock is necessary for robust transmission of fear during a social interaction between rats.
What happens during prior experience with shock that makes an animal respond to the distress of others? Is it just the experience of an aversive event? Is learning involved? To test these possibilities, we performed experiments where receiving footshock could be dissociated from fear learning. We found that rats that receive shocks but were not allowed to express fear responses prior to the social interaction did not display vicarious fear, even when they learned to fear the environment where footshocks were delivered. Thus, experiencing footshocks or contextual fear learning per se was not sufficient to facilitate vicarious fear.
One possibility is that stress during prior experience sensitizes the amygdala, thus determining the strength of the transmission of fear during the social interaction. To test this we measured corticosterone levels from animals that experienced immediate shocks (without fear learning), and compared them to animals that received spaced shocks in a familiar environment (yields fear learning and facilitates vicarious fear). We found that shock alone is a weak stressor, which might account for the absence of response of these animals to the display of fear by their con-specifics. Future experiments will be conducted to further elucidate the role of stress in this process.

Title: Adolescent traumatic stress experience shapes adult fear conditioning responses in rats

Authors: *N. L. MOORE, S. GAUCHAN, R. F. GENOVESE
Ctr. for Military Psychiatry and Neuroscience, Behavioral Biol. Br., Walter Reed Army Inst. of Res., Silver Spring, MD

Abstract: Recent studies have brought attention to the possibility that early-life traumatic stress exposure may influence the response to stress in adulthood. In order to better characterize these potential developmental alterations, a traumatic stress paradigm (underwater trauma, UWT) was used to model an intense developmental stress event during adolescence and evaluate behavioral effects lasting into adulthood. Adolescent rats (postnatal day 37) were exposed to UWT or swim without submersion. Behavioral evaluations using an elevated plus maze (EPM) and acoustic startle tests were conducted at baseline, immediately after UWT, and seven days later. Rats were then allowed to reach adulthood and fear conditioned using light and sound (conditioned stimulus) paired with a footshock (unconditioned stimulus). Testing was conducted the day before footshock, and immediately afterward. UWT during adolescence decreased open-arm time on the EPM through the seven-day testing timepoint. Testing before fear conditioning revealed similar pattern of behavior on the EPM in early adulthood regardless of adolescent treatment condition. However, following footshock, preliminary data suggest a differential change in both serum corticosterone and EPM activity across adolescent treatment conditions. These data suggest that alterations in fear conditioning response may be found in adult rats exposed to a developmental traumatic stress, relative to rats that were not stressed during the adolescent developmental period.

Title: Oxytocin in the central nucleus of the amygdala mediates social buffering of fear in rats

Authors: *E. M. RICKENBACHER[1], M. MOITA[2]
[1]Radiology, [2]Behavioral Neurosci., Champalimaud Fndn., Lisboa, Portugal

Abstract: Social interactions can decrease anxiety and fear in a variety of circumstance, a phenomenon known as social buffering. Even tough oxytocin has been implicated in this process, its underlying neural mechnisms remain poorly understood. We use auditory fear conditioning, during which an animal can learn to fear a neutral tone when it is paired with aversive footshocks, to test the effect of social buffering on fear conditioned rats. We conditioned rats to fear a tone and the next day, we exposed them to the tone in the presence or absence of their cagemate. We found that rats tested in the presence of their cage-mate showed less freezing than if tested alone. In addition, when tested again, now alone, rats that were previously exposed in the presence of their cagemate still froze less than the ones exposed alone showing that social buffering has long lasting effects on fear. Finally, we are currently testing the role of oxytocin in the central nucleus of the amygdala (CeA), a major output station that controls several defense responses. Preliminary data suggests that blocking oxytocin in CeA blocks the immediate and long lasting effect of social buffering on freezing.

Title: Neural activity of Purkinje cells and IPN neurons covaries with theta oscillations in the cerebellum during trace eyeblink conditioning

Authors: *C. HOU, L. HOFFMAN, S. BERRY
Psychology Dept., Miami Univ., Oxford, OH

Abstract: The cerebellum is an essential brain structure for acquisition of trace eyeblink conditioning. Purkinje cells in the cerebellar cortex receive input from climbing fibers and parallel fibers, projecting to the interpositus nucleus (IPN), which facilitates the acquisition of conditioned responses (CRs). The firing patterns of Purkinje cells and neurons in the IPN reflect cerebellar information processing during training, which predicts how well-learned responses are executed. In the current study, theta oscillations in the IPN were used as the criteria for triggering training trials. For cerebellar theta-triggered rabbits (T+), a trial was initiated when the proportion of theta was high for ~1 second immediately before the trial. For cerebellar nontheta-triggered rabbits (T-), a trial was initiated when there was virtually no theta oscillation for a ~1 second pretrial period. Upon reaching behavioral asymptote, Purkinje cells from both T+ and T- groups were observed to increase their firing rates after the onset of the tone, compared to their responses at the beginning of training. Purkinje cell activity during the trace period, however, varied according to T+ or T- training. More Purkinje cells displayed excitatory activity during the trace in the T+ group, compared to the T- group. Also, cerebellar T+ or T- training was found to affect when the inhibition of Purkinje cells would occur, with T+ inhibition of cortex occurring more often in the second half of the trace period when IPN cells must fire if CRs are to occur. Many theories suggest that the cortical control of IPN is involved in precise, adaptive timing of the behavioral responses, with IPN disinhibition allowing CRs during the second half of the trace interval. Thus, increased IPN firing rates permitted by T+ training can activate significantly greater responses in the IPN late in the trace period, supporting the execution of adaptive, well-timed CRs. These results demonstrate that significant theta-related modes of cerebellar information processing accompany substantial differences in behavioral eyeblink conditioning.

Title: Theta-dependent hippocampal field potentials during delay eyeblink conditioning

Authors: M. A. SPIES, L. C. HOFFMANN, *S. D. BERRY
Psychology Dept., Miami Univ., Oxford, OH

Abstract: Previous research has demonstrated significant learning rate improvements during hippocampal theta during delay and trace eyeblink classical conditioning (EBCC). Neural correlates of these behavioral effects during trace EBCC have been reported, however these analyses have yet to be extended to delay EBCC. In the present study, two groups of rabbits received daily trials of delay EBCC in the explicit presence or absence of naturally occurring theta, while two additional groups were used as yoked behavioral controls. For rabbits trained in the presence of theta, local field potential analysis showed rhythmic time-locked post-trial theta across animals, corresponding to important behavioral learning milestones. Rhythmic oscillations were absent in the post-trial period in those animals trained without theta. Analysis of the yoked controls revealed the presence of time locked theta in response to conditioning stimuli, although the phase relationship varied across animals. These findings provide new insights into hippocampal functional and non-functional states during learning that is modulated by, rather than essentially dependent upon, hippocampal processes.

Title: Comparison of identified neural response profiles in CA1 and CA3 during theta-contingent eyeblink conditioning.

Authors: *J. J. CICCHESE, S. D. BERRY
Psychology, Miami Univ., Oxford, OH

Abstract: The hippocampus has proven to be a critical structure in the acquisition of trace eyeblink classical conditioning (EBCC). Many studies on the role of the hippocampus in associative learning have focused on neurobiological oscillations, particularly the hippocampal theta rhythm. Our lab has developed a brain-computer interface (BCI) capable of initiating conditioning trials in the presence (T+) or absence (T-) of hippocampal theta. Utilizing this BCI in conjunction with single-unit recording techniques, we have previously shown that interneuron firing behavior is highly correlated to hippocampal theta state in CA1. While these patterns have been identified in CA1, it is still unclear if theta-contingent training affects single-unit response profiles in other hippocampal subfields. In the present study, custom-made drives were used to lower multiple tetrodes into CA1 and CA3 of four groups of rabbits (Oryctolagus cuniculus) to allow for simultaneous recording from both subfields. Units were sorted and each was categorized based on firing properties as pyramidal cell or one of the known interneuron types. Response profiles of identified cell types were characterized across paired and unpaired presentation of the conditioning stimuli in both T+ and T- theta conditions. The results of the present analyses provide additional insight into our current understanding of theta modulated response properties of hippocampal CA1 and CA3 cell populations engaged during hippocampal-dependent forms of EBCC.

Title: Oscillatory potentials reveal differential information processing in hippocampus-dependent versus independent tasks based on theta state

Authors: *L. C. HOFFMANN, M. A. SPIES, S. D. BERRY
Dept Psychology, Miami Univ., OXFORD, OH

Abstract: The hippocampus plays a modulatory role in acquisition of delay eyeblink classical conditioning (EBCC), but as task demands increase in complexity, such as in trace EBCC, it becomes essential. Our lab has developed a brain-computer interface (BCI), which allows for the comparison of two naturally-occurring extremes of hippocampal functioning (theta and non-theta). Using this technology, we have demonstrated that the absence of pretrial theta impedes learning rate during delay EBCC, while the presence of theta significantly enhances learning rate during trace EBCC. The behavioral effect of hippocampal theta triggering is twice as strong for trace as it is for delay EBCC. Here, we present an analysis of differences in the hippocampal local field potentials that accompany the two-fold learning rate differences in these two behavioral paradigms. The neural data provide evidence that theta activity represents a specific, active state of the hippocampus that becomes more beneficial when the hippocampus is essential to the task (as in trace EBCC). In contrast, the non-theta condition is more disruptive to delay EBCC than it is to trace which may suggest a different role for hippocampal theta states depending upon whether the hippocampus is essential or part of a parallel, modulatory circuit. In full, these data support the growing evidence for the influential role of theta frequency oscillations in hippocampus-involved associative learning processes.

Title: Dialogue between the lateral habenula and the hippocampo-cortical system during the sleep-wake cycle and a spatial recognition test

Authors: *R. GOUTAGNY[1], J. JACKSON[2], M. LOUREIRO[1], J. CHAUMONT[3], S. WILLIAMS[2], P. ISOPE[3], J.-C. CASSEL[1], L. LECOURTIER[1]
[1]Univ. de Strasbourg, CNRS UMR7237, Strasbourg, France; [2]Dept. of Psychiatry, Douglas institute research center-McGill Univ., Montréal, QC, Canada; [3]INCI - UPR3212-CNRS, Strasbourg, France

Abstract: Recently, the lateral habenula (LHb), wich is directly or indirectly connected with the hippocampo-cortical system, has been postulated to play a role in hippocampo-cortical dependent processing of contextual informations and elaboration of spatialmemories. To test this hypothesis, we recorded local field potentials (LFP) simultaneously within the LHb, the CA1 area of the dorsal hippocampus (dHPC) and the medial prefrontal cortex (mPFC) in freely moving male Long-Evans rats (n=5), during a continuous 24-hour recording session as well as during a spatial recognition test in an open-field. During the 24-hour recording session, we first showed that local activity within the LHb was modulated according to brain states, with prominent theta rhythm during wake (W) and REM sleep. During these states, LHb theta oscillations were significantly coherent with both dHPC (0.72±0.022 during REM vs 0.64±0.03 during W, p=0.009) and mPFC (0.57±0.01 during REM vs 0.66±0.025 during W, p=0.0871). To test if the LHb can genuinely generate theta oscillations, we performed single-cell recordings in urethane anaesthetized rats (n=4) using glass microelectrodes and found LHb cells (n=5) which fire selectively during episods of cortical theta oscillations induced by tail pinch (theta-on cells) suggesting that local LHb circuits operate at theta rhythm. To further test whether these coherent theta oscillations might have a functional role in a dHPC-mPFC dependant task, we performed LFP recordings within the three structures during a spatial recognition test designed to evaluate reactions to changes in the spatial layout of three objects within an open-field (n=5 rats). To that matter, following three consecutive sessions during which the objects remained in the same location (habituation sessions), in a subsequent session (test session), whereas one of the objects was left in place (“unmoved” object), one object was placed at the former location of the remaining one (“replace” object), the latter being moved to a location previously free of any object (“moved to a new location” object). During the test session, rats preferentially explored the “moved to a new location” object ($p<0.01$), showing that they remembered the previous layout of the context. Interestingly, this preference for the “moved to a new location” object was correlated to a specific and significant increase in theta power within the LHb ($p<0.05$). In conclusion, we have shown for the first time that the LHb is functionally connected with the hippocampo-cortical system and that it plays a role in the processing of contextual informations and the elaboration of spatial memory.

Title: Evidence that focal hippocampal interneuron loss disrupts theta- and gamma- band activity

Authors: *C. A. ROSSI, M. J. LEHMKUHLE, F. E. DUDEK
Physiol., Univ. of Utah, Salt Lake City, UT

Abstract: Hippocampal theta (6-12 Hz) and gamma (40-100 Hz) activity are oscillatory local field potentials (LFPs) that are thought to play a critical role in the encoding and storage of new information. GABA-ergic interneurons are hypothetically involved in the generation and pacing of these oscillatory patterns of activity. The current study aimed to directly test the hypothesis that interneurons are responsible for local gamma and theta generation in the dorsal CA1 region of the hippocampus in mice.
Selective focal interneuron lesions were made by intrahippocampal injection of the targeted neurotoxin SSP-Saporin into dorsal CA1 in the hippocampus of GAD67-GFP transgenic mice. Chronic recording electrodes were also implanted in the lesion area. LFPs were monitored continuously, along with video recordings of the subjects, for a period of several weeks. LFP recordings were analyzed over 24-hour periods for the occurrence of theta- and gamma-band activity.
Analysis of LFP data revealed attenuation of both local theta and gamma activity in SSP-saporin-injected animals compared to controls.
These results suggest a direct role of GABA-ergic interneurons in the generation of local rhythmic activity in these two frequency bands, and, by extension, an important role in learning and memory processes.

Abstract: Gamma (30 - 80 Hz) and beta (13 - 30 Hz) frequency oscillations are found in neocortex and hippocampus and are thought to bind together different aspects of the stimuli and thus thought to be the substrate of cognition. With an interdisciplinary approach of a behavioral place avoidance task to test cognitive ability, injection of several drugs which influence gamma and beta oscillations, EEG and hippocampal local field potential (LFP) recordings, and a detailed hippocampal computer model, we showed that oscillation-modifying drugs change cognitive behavior in *in vivo* Alzheimer mouse models and WT mice just as predicted by computer simulations modeling their effects on gamma and beta oscillations: (1) J20 Alzheimer mouse models show slower learning curves than WT mice in the *in vivo* place avoidance task. (2) This is true as early as at 4 months of age, while robust Alzheimer pathologies have so far only been shown in J20 mice at 6 months of age. This seems to point away from static pathologies (like plaques) and point towards more fluid, physiological deficits (like oscillation deficits) as the origin of cognitive deficits in J20 Alzheimer mouse models. (3) *In vivo* EEG and hippocampal LFP recordings show reduced gamma and beta oscillations in J20 compared with WT mice (4) As predicted by the computer model the 5-HT_4 agonist RS67333, which depolarizes pyramidal cells and increases gamma and beta oscillation power, significantly improves learning in J20 mice. (5) 5-HT_4 agonists also influence learning in WT mice: they significantly improve cognition in bad learners, but reduce the cognitive ability of the best learners. This could be explained with the effect of 5-HT_4 agonists on gamma and beta oscillations and the assumption that cognition functions best with an optimal level of gamma and beta oscillations: According to this hypothesis the best learners should have an optimal level of gamma and beta oscillations. Further depolarizing pyramidal cells and increasing the oscillation power above this 'optimal' level will generate too synchronous oscillations which should impair information processing. (6) Contrary to its normal use to impair cognitive ability, but as predicted by its action on oscillations, the cholinergic antagonist scopolamine can *improve* learning under very special circumstances: Performance of the very best mice in the place avoidance set-up was impaired by the 5-HT_4 agonist RS67333 but is increased again by addition of scopolamine. This is consistent with the hypothesis that the 5-HT_4 agonist RS67333 and the cholinergic antagonist scopolamine influence cognition via gamma and beta oscillations.

Title: Hippocampal EEG power changes associated with novel object recognition

Authors: *S. HUITRON-RESENDIZ, A. J. ROBERTS
Dept Molec and Integ Neurosci MB-18 & Mouse Behavioral Assessment Core, The Scripps Res. Inst., LA JOLLA, CA

Abstract: Theta and gamma oscillations in the hippocampus have been related with attention and learning processes. While many studies have largely focused on the role of these EEG rhythms on working memory, only a few studies have attempted to evaluate these neuronal rhythms during a simple recognition task. Therefore, the goal of this experiment was to examine theta and gamma power in mice during the novel object recognition test. Under isoflurane anesthesia, a standard set of stainless steel screw electrodes was implanted in male C57BL/6J for chronic EEG recordings. The EEG was recorded from electrodes placed in the frontal and parietal bone over the hippocampus. One week after surgery, mice were habituated individually to their own recording chambers during 48 hours with food and water available ad libitum. After the habituation period was over, the EEG was recorded throughout novel object testing. One object (small plastic toy) was placed in one corner of the chamber, approximately 2cm from the walls. Mice were allowed to explore the object for five minutes, and then the object was removed from the chamber for one minute. The same object was moved back into the chamber in the same location, and then the mice were allowed to explore it for another 5 minutes. Then object was moved out for one minute. Four trials were done using the same object, whereas for the fifth trial a novel object was introduced into the chamber in the same position as the previous object. Mice were allowed to explore the object for 5 minutes. All behavior was video recorded and then the number of contacts each mouse made with the object was scored along trials. A contact was defined as a nose/object touching interaction or nose pointing at the object with the vibrissae moving, and within 0.5 cm of the object. The EEG was displayed on a computer monitor and stored with a resolution of 128 Hz in the hard drive of a computer for the off-line analysis of the

vigilance states and spectral analysis. In the object habituation trials, mice showed a reduction in the number of contacts along the trials, whereas during the novel object trial, the number of contacts was increased. The EEG power analysis showed a significant increase in the fast gamma power associated with detection of novelty (45.1-60 Hz), while both the slow gamma (30-45 Hz), and theta power (6-12 Hz) did not show significant differences, compared to baseline conditions. These data suggest that the fast gamma oscillations are a component of the hippocampus processes of novel object recognition.

Title: Theta phase precession of grid and place cell firing in 2d.

Authors: *A. JEEWAJEE[1,2,3], C. BARRY[4,3,5], C. LEVER[7], V. DOUCHAMPS[7], D. MANSON[6], N. BURGESS[3,5]

Abstract: Theta-phase precession (O'Keefe and Recce, 1993; Skaggs et al., 1996), a remarkably robust example of temporal coding in the brain, is found in two types of spatially tuned neurons in the hippocampal formation. It has been explored in some detail in place cells, and to a lesser degree in grid cells, with most analyses concentrating on firing on linear tracks. Here we characterize the theta-phase of firing of grid cells and place cells in rats foraging in open field environments. Firing phase relative to the theta rhythm of the local field potential is described as a function of the animal’s location within the current firing field relative to the running direction

during reasonably straight runs, extending the idea of “directional rate zones” (Burgess et al., 1993; Huxter et al., 2008). Consistent with data from linear tracks (Hafting et al., 2008), phase precession is most reliable in non-directional grid cells from superficial layers, while directional (or conjunctive) cells exhibit no or extremely weak phase precession. Place cells and grid cells with phase precession show firing phases that transition from “late” phase (and low phase variance) in the first half of the field, to an earlier phase (and high phase variance) after the animal moves through the field by a distance equivalent to the field radius. This relatively sharp transition is obscured when combining runs into “linearized” plots that ignore the lateral displacement of the run from the field centre.

Title: Delta phase modulation of gamma oscillations in the BLA and mPFC during fear learning and expression in freely moving rats

Authors: *T. E. MADSEN[1,3], D. G. RAINNIE[2,3]
[1]Neurosci. Grad. Program, [2]Psychiatry and Behavioral Sci., Emory Univ., Atlanta, GA;
[3]Behavioral Neurosci. and Psychiatric Disorders, Yerkes Natl. Primate Res. Ctr., Atlanta, GA

Abstract: In mice, fear memory recall has recently been shown to correlate with the appearance of a low theta (4-6 Hz) oscillation in local field potentials (LFPs) that is expressed coherently between the basolateral complex of the amygdala (BLA) and the medial prefrontal cortex (mPFC, reviewed in Pape & Pare 2010). However, in rats, we have previously demonstrated that a similar increase in power and coherence between LFPs in the BLA and mPFC occurs instead in a tightly tuned delta (1-4 Hz) frequency band during fear memory acquisition and recall. Moreover, spectral analysis further revealed a strong increase in gamma (45-65 Hz) power in LFPs in both the BLA and mPFC, especially immediately after the shock during fear acquisition and to a lesser extent at the end of the cue presentation early in extinction training. In the hippocampus, the amplitude of gamma can be modulated by the phase of theta oscillations. Furthermore, a 4 Hz phase modulation of gamma amplitude has recently been reported in the prefrontal cortex of rats performing a working memory task. Hence, we hypothesized that gamma may be similarly modulated by delta in the rat BLA and mPFC during fear learning and expression.

Here, we report that the amplitude of the gamma oscillations is indeed dramatically modulated by the phase of the delta oscillations, specifically during and after the presentation of conditioned tones. The raw LFPs were first corrected for frequency-varying timing delays that occur as a result of analog filters in the headstage and pre-amplifier using Plexon's FPAlign. Custom Matlab scripts, adapted from those provided by the Kopell lab, were then used to filter the aligned LFPs into delta and gamma bands and then perform a Hilbert Transform to extract the phase and amplitude envelope, respectively. The Modulation Index (MI) and its significance were then calculated by the method described in Tort *et al* 2010. In four of the five rats tested, the amplitude envelope of the gamma (45-65 Hz) filtered LFPs was significantly modulated by the phase of delta (1-4 Hz) filtered LFPs, especially in the mPFC during fear recall. Specifically, the gamma amplitude was highest approximately 20° past the trough of the delta filtered LFP. The fifth rat showed no peak in the gamma frequency range of its power spectra.

To our knowledge, this is the first demonstration of cross-frequency coupling within the amygdala. With an eye to demonstrating a functional relevance for this phase-amplitude modulation in affective processing, ongoing analysis is focused on examining the change in MI over time, both within and across trials and phases of fear and extinction learning.

Title: Hippocampal-prefrontal cortical neuronal assemblies in a delayed non-match to position operant working memory task

Authors: M. T. KUCEWICZ[1], M. D. TRICKLEBANK[2], E. S. J. ROBINSON[1], *M. W. JONES[1]

Abstract: Rhythmic network activity supports cognitive processing in hippocampus and prefrontal cortex and is presumed to underpin behavior-dependent coordination of neuronal assemblies. However, the nature of assembly formation and coordination across multiple brain regions, learning stages and cognitive task phases remains largely undocumented.
Simultaneous tetrode recordings from dorsal CA1 and the medial prefrontal cortex (mPFC) of six adult rats learning and performing a working memory-dependent, delayed-non-match-to-position (DNMTP) operant task were used to detect groups of co-activated neurons using methods described by Lopes-dos-Santos et al. (2011). Sample, delay and response phase-selective activity included hippocampal units showing discriminative encoding of position and prefrontal units that maintained differential firing on sample specific trials throughout entire delay periods (up to 16s). Of 350 CA1 and 372 mPFC units isolated, approximately 30% and 20% respectively participated in coactive assemblies: distinct assemblies included 37 intra-CA1, 26 intra-mPFC and 26 incorporating units from both CA1 and mPFC. Individual assemblies were consistently and preferentially active during either sample, delay or choice stages of the task. Accordingly, assembly-active units showed significantly more task phase-specific firing than other task-active neurons. The number of delay-selective mPFC assemblies detected increased as delay was extended from 0-16s.
The spike-timing of units contributing to hippocampal-prefrontal cortical assemblies was highly correlated, and unit pair cross-correlations strongly modulated in the theta frequency range (approximately 5Hz). This rhythmic modulation of assembly activity was disrupted by CP55940, an agonist of cannabinoid receptors that severely reduced the number of cross-structure assemblies and impaired DNMTP performance (cf Kucewicz et al. 2011).
Our results suggest that loading, maintenance and retrieval of working memory is reflected by

coordinated assemblies of highly specialized neurons within and across cortical-limbic networks.

Title: An improved permutation test to detect significant spike-LFP phase-locking reveals frequency-specific synchronization patterns of single ACC/PFC neurons

Authors: *T. WOMELSDORF[1], S. ARDID[2], S. EVERLING[3], M. VINCK[4]
[1]Biol., York Univ., Toronto, ON, ON, Canada; [2]Biol., York Univ., Toronto, ON, Canada; [3]Western Univ., London, ON, Canada; [4]Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: We develop a novel permutation test to detect at which frequency-bands single neurons reliably synchronize to Local Field Potential (LFP) oscillations. In many applications, the preferred frequencies of spike-LFP locking are not a priori known, e.g. because multiple rhythms co-occur in the same area.
The structure of the statistical algorithm is as follows. A permutation distribution is constructed under the null hypothesis of no significant spike-LFP phase-locking such that statistical dependencies between spike phases (Vinck et al 2011, J Comp Neurosci) and across frequencies are preserved. We then identify clusters of significant frequencies (Rayleigh $p<0.05$), and compute for each cluster the sum of PPCs (Pairwise Phase Consistency) (Vinck et al 2010, NeuroImage), a statistic that is unbiased by spike number and controls for dependencies between spike phases within trials. Significance is then determined based on PPC cluster-mass or on the maximum PPC value. A peak-detection algorithm based on local minima and maxima of the PPC spectrum is employed to detect significant peaks within significant frequency bands. Our

procedure has two main advantages relative to standard available techniques to detect significant phase-locking. By incorporating that many dependent (across frequencies) statistical (Rayleigh) tests are performed the algorithm shows enhanced sensitivity compared to other Bonferroni or FDR multiple comparison correction techniques. In addition, it avoids the problem that the Rayleigh test is sensitive to non-Poissonian history effects (e.g., bursting) within the same trial, meaning that the underlying assumptions of the Rayleigh test are typically violated.
We use the technique to analyze population-wide synchronization patterns in an ACC/PFC dataset (Kaping et al 2011, PLoS Biol) containing >800 neurons. In the majority of cells (>70%), significant clusters of frequencies are detected. For >20% of cells, multiple clusters of significant frequencies are detected. The distribution of preferred frequencies in the ACC/PFC reveals frequency-specific synchronization patterns relative to the same and different electrodes within the ACC/PFC.

Title: GABA blockade in the medial septum disrupts hippocampal theta and leaves place cell coding intact

Authors: *K. A. BOLDING[1], S. E. FOX[2], R. U. MULLER[2]
[1]Dept. of Physiol., SUNY Downstate Med. Ctr., BROOKLYN, NY; [2]Physiol., SUNY - Downstate Med. Ctr., Brooklyn, NY

Abstract: As an animal explores its environment, individual 'place cells' in the hippocampus demonstrate location-specific firing, representing a neural substrate for the computations involved in spatial navigation. Also during active exploration, the hippocampal local field potential is dominated by a 5-12 Hz oscillation known as theta rhythm. Place cell firing patterns are exquisitely organized in relation to the field theta oscillation, raising the possibility that this temporally-structured activity contributes to spatial processing. Hippocampal theta can be disrupted by lesioning or inactivating the medial septal area in the basal forebrain, and these manipulations affect place cell firing characteristics. However, the medial septum serves a dual role in modulating hippocampal activity as the rhythmic pacemaker for theta oscillations and the

primary source of cholinergic input to the hippocampus. To assess the relative importance of these functions for location-specific coding, hippocampal local field potentials and place cell activity were monitored after intraseptal injection of tetracaine (local anesthetic), muscimol (GABA-A agonist), or gabazine (GABA-A antagonist). Septal inactivation by injection of either tetracaine or muscimol reduced theta power in the local field potential and place cell activity in the CA1 and CA3 regions of the hippocampus. Injection of gabazine robustly disrupted hippocampal theta oscillations while increasing power in the delta and fast gamma (50-90 Hz) ranges. These results indicate that GABAergic transmission in the medial septum is necessary for theta rhythmic activity and that septal output influences a broad range of oscillatory activity in the hippocampus. During extended periods of minimal theta power in the hippocampus, place cell activity was not substantially altered. This observation limits the role for theta oscillations in the expression of location-specific coding and emphasizes the influence of cholinergic modulation on spatial processing in the hippocampus.

Title: Hippocampal theta reflects on anticipation of food localization and consumption

Authors: *E. WASSERMAN, T. PELC, M. MINTZ
Tel Aviv Univ., Tel Aviv, Israel

Abstract: The dorsal hippocampus has a key role in construction of cognitive spatial maps, as evidenced by spatially-related activity of its place-cells. Analysis of the related place-fields demonstrates skewed distribution with high resolution around zones with emotive significance. This 'remapping' may be induced by emotive appraisal toward objects in the space, for example by the amygdala, or by emotive appraisal of the spatial context, for example by the ventral hippocampus. However, the mechanism of spatial remapping by emotion is presently not known. We argue that the mediating mechanism is the hippocampal theta rhythm that paces the place cell firing, and which disruption compromises place cell functionality and disorganizes behavioral navigation. Locomotion and theta rhythm activity in the dorsal hippocampus was monitored in rats foraging for food in a maze consisting of home-base and target chambers

connected by an alley. Rats experienced four consecutive conditions: no food in the maze; small food pellet found and consumed in the target chamber; large food pellet found in the target chamber and carried to the home-base chamber where it was consumed, i.e., hoarding; and finally, no food in the maze. HHT analysis demonstrated an increase in theta frequency along the trajectory toward the small and large food pellet in the target chamber and along the trajectory back toward the home-base chamber where the large food pellet was consumed. In contrast, theta frequency decreased along the trajectory to the target chamber when food was omitted. These findings suggest that theta rhythm projects on the dorsal hippocampus the emotive appraisal of the spatial trajectories. Currently we aim to test the impact of the observed changes in theta frequency on the representation of the trajectories by the hippocampal place-cells.

Title: Multiplexing of theta-nested gamma oscillations and grid firing fields in an attractor network model of layer II of the medial entorhinal cortex

Authors: *L. SOLANKA, H. PASTOLL, M. C. W. VAN ROSSUM, M. F. NOLAN
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Grid cells in the medial entorhinal cortex (MEC) encode location through firing fields that form grid-like maps of the environment. At the same time network activity in the MEC is dominated by oscillations in the theta (4-12 Hz) and gamma (30-100 Hz) bands. The relationship between oscillatory activity and grid firing is not known. Our recent experimental data established that feedback inhibition between excitatory stellate cells and inhibitory fast spiking interneurons dominates the synaptic connectivity in layer II of the MEC. To determine if this circuit is sufficient to explain both the network oscillations and grid firing fields, we constructed a network of model stellate cells and interneurons. In this model, stellate cells connect exclusively to interneurons, while interneurons contact only stellate cells. We show that external

excitatory conductances can drive the network into an attractor state. Feedback inhibition onto the model stellate cells has a synchronizing effect. Synaptic input to both populations of neurons is synchronized in the gamma frequency range (30 - 100 Hz). When coupled with a theta modulated external drive (8 Hz), we observed network synchronization during the trough of the theta signal only. When the borders of the network are connected with a twisted torus topology (Guanella et al. 2007) and velocity modulated inputs are applied to the circuit, excitatory neurons in the circuit generate grid-like firing fields. Due to limited stability of the attractor, the grid fields were blurred. However, it was possible to obtain stable grid fields by including a place cell resetting mechanism as an additional input to the network (Guanella et al. 2007). These results demonstrated that the same local circuit architecture - feedback inhibition - supports emergence of attractor states and nested gamma oscillations. This has implications for mechanisms of both formation of grid-like receptive fields as well as population coding and information transmission between brain areas.

Title: Theta dynamics: The relationship between theta frequency and locomotor speed in familiar and novel environments

Authors: *J. R. HINMAN[1], L. L. LONG[1], M. A. ESCABI[2,3], J. J. CHROBAK[1]
[1]Dept. of Psychology, [2]BiomedicalEngineering, [3]Electrical and Computer Engin., Univ. of Connecticut, Storrs, CT

Abstract: Changes in theta amplitude and frequency have been linked to the execution of ongoing motor programs, as well as cognitive processes such as attention, encoding and retrieval. Theta in the rat hippocampus exhibits significant variation across the laminarly arranged somatodendritic field of hippocampal neurons, as well as across the septotemporal (long) axis. This variation can be correlated to ongoing changes in a rat’s behavior, environment and

cognitive performance. We have previously demonstrated that the relationship between locomotor speed and theta amplitude systematically decreases across the long axis. In contrast, the relationship between speed and theta frequency is invariant across the long the axis. Previous demonstrations of the relationship between speed and theta frequency have been limited to a single recording condition, yet there are numerous demonstrations of theta frequency changing across conditions (e.g. novelty).
We asked whether the relationship between speed and theta frequency changes across multiple sessions in a familiar and a novel environment. Electrodes were implanted at multiple septotemporal levels of CA1 and local field potential theta signals were recorded as rats (N = 10) ran laps around a rectangular linear track. Three recording sessions (10 minutes in length) were conducted each day for multiple days in a familiar environment and then multiple days in a novel environment. Despite performing a well-learned task in a familiar room, theta frequency systematically increased within sessions, as well as across sessions within a single day at sites across the long axis. Upon exposure to the novel environment theta frequency decreased compared to the familiar environment, although this decrease was relatively short lived. By the second session in the novel room theta frequency had returned to levels similar to the familiar room. A multiple regression analysis was conducted that included time within a session and speed as predictors of theta frequency and it was observed that the relationship between speed and theta frequency positively covaried in both the novel and familiar environments. Yet in both environments higher intercepts were associated with lower slopes, thus indicating that the relationship between locomotor speed and theta frequency is not constant. This may be a fundamental feature of the relationship between speed and theta frequency.

Abstract: The neural substrate of memory formation resides within the function connectivity of ensembles of neurons and their dynamical interactions. The laminar and afferent organization of the hippocampus allows for the observance of synchronizing rhythms such as theta (6-12 Hz). Theta is observed in the extracellular local field potential (LFP) where these potentials reflect the summation of synaptic potentials that determine neuronal discharge and orchestrate ensemble interactions. Endless evidence now demonstrates that variation in the theta signal is predictive of memory encoding and subsequent cognitive performance during retrieval or recognition tasks. Previously, we have reported a dominant relationship between speed and theta power at septal hippocampal sites and that this relationship diminishes systematically with distance from the septal pole of the hippocampus in both CA1 and DG. The current data focus on the relationship between acceleration and velocity (directionality) and how these indices contribute to variability in the theta signal. Recordings were obtained while rats shuttled between both ends of a linear track for a palatable food reward. As previously shown, theta amplitude was positively modulated by speed at septal CA1 sites with speed accounting for 40-80% of the variability. In addition to speed, positive acceleration significantly accounted for 5-15% of theta variability, although no significant relationship was observed for deceleration (negative acceleration). Velocity (directionality) did not account for any significant modulation of theta amplitude at CA1 sites. Currently we are assessing the relationship between acceleration and velocity at DG sites as well as variability at distinct laminar positions within CA1 (eg, stratum oriens, radiatum and stratum lacunosum moleculare). These findings demonstrate that locomotor speed and positive acceleration are main predictors of theta amplitude in septal hippocampus. An open question remains on whether speed and acceleration are constant contributors to variation in the theta signal or whether behavioral/cognitive context alter the relationship between speed/acceleration and theta amplitude. Importantly, a better understanding of the relative contribution of these highly quantifiable variables and their potential dynamic variation should facilitate analyses of how variation in theta relates to cognitive/memory processes.

Title: Theta dynamics: Septotemporal differences in response to habituation, spatial novelty and the absence of expected reward

Authors: *J. CHROBAK[1], L. L. LONG[1], M. A. ESCABI[2,3], J. R. HINMAN[1]

Abstract: Novel and unexpected experiences engage neural circuits including the hippocampus. The once-thought regular drumbeat of the hippocampal theta signal has experienced a resurgence of research interest with evidence demonstrating its dynamic qualities and its predictive relation to memory processing in humans. The theta signal exhibits variation within the laminarly arranged somatodendritic field of hippocampal neurons, as well as across the septotemporal axis. Local theta signals correlate with changes in a rat's behavior, environment, experience and memory performance. The present study examined theta local field potential signals at sites across the septotemporal axis of the CA1 region while rats (N = 10) ran unidirectional laps around a rectangular linear track over repeated exposures to both a familiar room and a novel room, as well as to the novel experience of the absence of expected reward. To ensure that any changes in theta power did not result from changes in running speed (Hinman et al 2011), we conducted a multiple regression analysis to take the speed of the animal into consideration.
In agreement with previous findings (Hinman et al., 2011), theta power habituated at temporal CA1 sites, but not at septal sites, across multiple sessions within a single day in a familiar room. Exposure to the novel room resulted in a significant increases in theta power at both septal and temporal CA1 sites compared to the familiar room. Theta power habituated in both septal and temporal CA1 across sessions on the first day in the novel room, although habituation was greater in temporal CA1 as compared to septal CA1. Theta power in the novel room stabilized to levels observed in the familiar room within three days. Exposure to the novel experience of the absence of an expected reward resulted in a substantially greater increase in theta power at temporal as compared to septal CA1 sites. The findings demonstrate dynamic septotemporal variation in the theta signal: they highlight conditions that may engage the temporal hippocampus and provide clues into functional differentiation across the septotemporal axis of the hippocampus.

Title: The role of L-type voltage-gated calcium channels in age-related cognitive decline

Authors: *S. J. MOORE[1], J. N. SLATER[1], G. G. MURPHY[1,2]
[1]Mol. & Behavioral Neurosci Inst., [2]Mol. and Integrative Physiol., Univ. of Michigan, Ann Arbor, MI

Abstract: Although cognitive impairments in the aged population are generally associated with neurodegenerative disorders like Alzheimer's disease, they more often occur in the absence of any overt neurological pathology. However, the neurobiological mechanisms underlying this age-related cognitive decline remain relatively poorly understood. In rodent models, aging is associated with an up-regulation of L-type voltage-gated calcium channels (L-VGCCs) and this increase has been correlated with poorer performance in a hippocampus-dependent learning and memory task. We have used a novel transgenic mouse line in which the αCamKII promotor drives over-expression of the CaV1.3 subtype of L-VGCCs in young animals (CaV1.3 OE) to directly examine the relative contribution of this increased expression to cognitive deficits. While CaV1.3 OE mice exhibit normal sensory, motor, and anxiety-like behaviors, they show impairments in performance on several learning and memory tasks, including the Morris water maze and discrimination in contextual fear conditioning. Taken together, our results suggest that the age-dependent up-regulation of CaV1.3 contributes to cognitive deficits in learning and memory. Because this increase precedes many other age-related changes, CaV1.3 may represent a novel therapeutic target for the amelioration of age-related cognitive decline.

Title: The PKCβ selective inhibitor, Enzastaurin, impairs learning and memory without changes to hippocampal transcription

Authors: *M. TURK[1,2,3], S. E. MENNENGA[1], A. SINIARD[2,3], J. J. CORNEVEAUX[2,3], L. HEWITT[1], C. TSANG[1], J. CASELLI[1], B. B. BRADEN[1], H. A. BIMONTE-NELSON[1,3], M. J. HUENTELMAN[2,3]

Abstract: Enzastaurin (ENZ) is a Protein Kinase C-β (PKCβ) selective inhibitor currently in Phase I/II trials as a treatment for various types of difficult to treat chemo-resistant tumors. PKCβ is an important enzyme in modulating a variety of neuronal functions. In particular, previous rodent studies have reported a deficit in spatial and fear-conditioned learning and memory with decreased endogenous concentration of PKCβ. Due to ENZ's mechanism of action, the present study investigated the consequences of ENZ on learning and memory in 12-month-old Fischer-344 male rats. Rats were treated daily with either vehicle (polyethylene glycol, n=10) or subcutaneous injections of ENZ (25mg/kg; 0.4mL, n=8), and tested using a Morris Water Maze (MWM) 30 minutes post-injection. The MWM is a spatial memory task that is sensitive to age-related memory changes, and depends on hippocampal integrity. Swim distance to the platform was calculated using tracking software (Ethovision XT 5.1, Noldus). Each rat underwent six trials a day for three days. A probe trial was performed on the final day as a seventh trial. The group treated with ENZ had higher swim distance on days two and three ($p<0.05$), indicating impaired spatial reference memory, and also showed decreased overnight retention ($p<0.05$).. However, there were no differences during the probe trial, in which the platform was removed from the maze, indicating localization to the target maze quadrant. Immediately after the final day of testing, rats were anesthetized with inhalent isofluorane and brains were rapidly dissected and frozen. RNA from the CA1/CA2 region of the left hippocampus was extracted, isolated, and purified for mRNA next generation sequencing (Illumina) to examine the potential transcriptional differences between the two groups. Data were analyzed using Cufflinks to quantitate gene expression in Fragments Per Kilobase of transcript per Million mapped reads (FPKM). No significant transcriptional changes were found at the gene expression level (using a Kruskal Wallis test) indicating that the consequences of ENZ are exerted primarily through a direct effect on the target kinase, and not at the transcriptional level. These results suggest that PKCβ inhibition impairs spatial memory performance in middle-aged animals, and support the incorporation of cognitive testing in future human clinical trials that utilize this drug to determine if impairments are noted concordant with ENZ administration in humans as well.

Abstract: It is well established that hypertension (HTN) in humans can lead to regional brain atrophy and cognitive decline. With a high prevalence in the community-dwelling elderly population, HTN may be an important factor influencing the development and progression of cognitive aging. We sought to investigate the effects of HTN on gray matter volume from magnetic resonance imaging (MRI) scans of the brain obtained in a rodent model of HTN. Since the onset and progression of HTN in humans often occurs gradually after middle-age, we used transgenic rats that allow for the gradual induction of HTN in middle-aged animals (Mitchell et al., 2006). The inbred male rats, with a Fischer 344 background, have the cytochrome P450 promoter (Cyp1a1) inserted to up-regulate the expression of the mouse renin (Ren2) gene. Administration of 0.15% indole-3-carbinol (I3C) activates the Cyp1a1 promoter to induce a gradual onset of HTN. We administered an I3C augmented diet at 16 months of age over a 6-week interval to produce a HTN group of Cyp1a1-Ren2 rats (N = 5), whereas the control group

of transgenic rats (N = 5) received normal food pellets. Volumetric T2-weighted MRI scans were acquired at 7.0 T with 150-micron isotropic voxel resolution for both the HTN and control groups. Multivariate network analysis with voxel-based morphometry (VBM) and the Scaled Subprofile Model (SSM; Alexander and Moeller, 1994) was used to identify a regional network pattern of MRI gray matter that differed between the groups. The HTN group had higher mean systolic (p < 0.009) and diastolic (p < 0.016) blood pressures during the 6-week interval than controls. Additionally, when analyzed as a proportion of body weight, heart and kidney weights were increased for the HTN group compared to controls (p < 0.009). SSM analysis of MRI VBM with bootstrap re-sampling of the HTN and control groups combined identified two regional network patterns of gray matter that distinguished the hypertensive rats from controls (p < 0.009). This linearly combined pattern was characterized by gray matter reductions in the vicinity of the thalamus, basal ganglia, cerebellum, and a region of the hippocampus with relative increases observed in selective frontal and temporal areas. Together, these findings provide preliminary support for the use of the Cyp1a1-Ren2 rat to help advance translational research on the cerebrovascular effects of HTN during aging. The use of such transgenic rodent models combined with high resolution MRI and network analyses may aid efforts in the evaluation of new treatments and prevention therapies for the brain changes associated with healthy and pathological aging.

Title: Changing characteristics of neural stem cells across the lifespan during aging

Authors: *K. SMITH, C. A. BARNES, M. J. CORENBLUM, L. MADHAVAN
Neurol., The Univ. of Arizona, Tucson, AZ

Abstract: In the context of understanding plasticity in the brain during aging, we have begun to characterize the properties of neural stem cells (NSCs) obtained from the subventricular zones of Fisher 344 rats in vitro over an aging continuum of 2 (adolescent), 9 (mature), 15 (middle-aged) and 24 (old) months. Characterization in this manner provides a comprehensive view of the population as it changes throughout a lifetime rather than comparing only the young and old endpoints. To begin with, significantly greater numbers of NSCs were isolated from the more younger (2, 9 months) than the more older (15, 24 months) animals. The isolated adolescent, mature, middle-aged and old NSCs differed in size and morphology although being immunophenotypically similar with no difference in the expression of NSC markers, Nestin or Sox2. The proliferative capacity of the NSCs was next determined by quantifying sphere formation using a serial dilution assay as well as incorporation of the thymidine analog bromodeoxyuridine (BrdU). The dilution assay indicated that adolescent and mature younger cells formed significantly greater number of neurospheres than the middle aged and old cells at every dilution level. Concurrent with this, a significant decline in the fraction of BrdU labeled cells was observed with increasing age. Interestingly, in both the dilution and BrdU assays, NSCs isolated from the middle-aged (15 months) animals showed greater impairment in proliferative ability compared to the cells from old (24 months) animals. In support of the proliferation data, survival of NSCs measured using a live/dead cell assay did not show any significant differences between adolescent, mature and old age groups, but the middle-aged cells displayed a considerably greater fraction of dead cells. Further, adolescent, mature, and old cells were found to be capable of being propagated in culture for a greater number (>15) of passages than middle-aged cells (<10). NSC differentiation was also examined. While the number of RIP+ oligodendrocytes remained fairly constant, TUJ1+ neurons declined, and S100B+ astrocytes increased with age. Overall, the results indicate (1) increased senescence, (2) reduced survival, proliferation, and neuronal differentiation of NSCs as aging progresses, and (3) suggests a particular vulnerability of cells during middle-age which needs to be analyzed further. These ongoing studies will help establish baseline changes in characteristics of NSCs throughout the natural lifespan, and provide a framework for further investigations of underlying factors, as well NSC potential to modify the aged brain.

Title: Aging does not affect the proportion of dorsal medial entorhinal cortex cells active during track running behavior.

Authors: *J. LIANG[1,2], J. P. LISTER[1,2], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Previous work has shown that hippocampal place cells in aged rats show changes in their population dynamics: in CA1 there are errors in retrieving the correct map for a known location (e.g., Barnes et al., 1997), and in CA3 they exhibit difficulty in establishing a new map for a novel location (Wilson et al., 2005). The entorhinal cortex provides input to the hippocampus and could contribute to these observed age-related changes in the population code for space. The medial entorhinal cortex (MEC) contains "grid cells" that fire in a highly spatially regular fashion (e.g., Hafting et al., 2005). These cells fire in repeating patterns across an entire environment and are believed to contribute significantly to the spatial signal within downstream hippocampal regions. The current experiment investigated whether aging affects population activity in MEC during track running, by quantifying expression of the immediate early gene *Arc* using the "catFISH" method (Guzowski et al., 1999). The rigid kinetics of *Arc* localization to distinct cellular compartments allows this gene to mark neuronal activity during discrete behavioral epochs. Young (9 months) and old (24 months) Fischer 344 male rats (N = 24 at each age) were divided into three groups: caged control (CC), maximal electroconvulsive shock control (MECS), and track running behavior. Rats learned to run alternating clockwise and counterclockwise laps on a circular track (48 inch diameter) for food reward. For the experiment, CC rats were sacrificed immediately from home cages, and the MECS group was sacrificed following a shock that activates Arc expression in all neurons capable of expressing the gene. Rats in the running group performed two 5 min sessions of track running, separated by a 20 min rest period in their home cage. Immediately after the second session, animals were sacrificed. After sacrifice, brains were flash-frozen to preserve mRNA, sectioned on a cryostat, stained for *Arc* expression with fluorescence *in situ* hybridization, and the dorsal MEC was examined in each rat (3 sections per brain). Neurons were quantified as nuclear positive (Nuc+), cytoplasmic positive (Cyto+), or double-labeled (Dbl+). Repeated measures ANOVA revealed a significant ($p<0.01$) effect of the *Arc*-compartment factor - there was a significantly higher proportion of Dbl+ neurons than Nuc+ or Cyto+ in both age groups. The age factor was not significant,

indicating that the ability of MEC to reactivate the same populations during the two sessions of track running in the same environment is not affected by age. This suggests that at least the cellular composition of the path integration input to the hippocampus is preserved during aging.

Title: Effect of aging on the activity pattern of Arc expression in the deep layers of lateral entorhinal cortex.

Authors: *J. P. LISTER[1,2], S. J. CLASEN[1,2], A. L. HARTZELL[1,2], S. N. BURKE[1,2], C. A. BARNES[1]
[1]Evelyn F. McKnight Brain Inst., Univ. Arizona, TUCSON, AZ; [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Age-related changes in hippocampal function have been studied extensively, but less is known about the effect of aging on input from entorhinal cortex. Neurons of lateral entorhinal cortex (LEC) lack spatial specificity in their firing properties (e.g., Hargreaves at al., 2005) and are thought to provide the hippocampus with information about the contents of the environment. Data from earlier experiments indicate that neither age nor changing environmental features altered the proportion of cells with *Arc* activation in superficial layers of LEC (Lister et al., SfN 2011). These data were not consistent with the suggestion that object identity information was carried by LEC cells in this layer, leaving open the possibility that perhaps cells in the deep layers may do so. Here we report results from deep layers of LEC in 24 young and 24 old F344 rats. There were four groups: 1) caged control, 2) positive control with electroconvulsive shock, inducing maximal expression of the immediate early gene *Arc*, 3) an A/A behavioral group that explored for two 5 min sessions in a box populated with the same set of 5 objects during both sessions, and 4) an A/B group, identical to A/A with entirely dissimilar objects during the second session compared to the first. Behavior rats had a 20 minute rest period between sessions and were sacrificed immediately after the second session. This design tests the hypothesis that the

identity of objects will be critical to individual neuron activity and that this function will be affected by aging. The kinetics of *Arc* mRNA within discrete intracellular compartments (nucleus or cytoplasm) allows each *Arc*+ neuron to be identified as active within a specific temporal window, including the ability to identify cells active in both sessions. 3 sections per brain from posterior LEC were stained for *Arc* expression via fluorescence *in situ* hybridization and imaged using confocal microscopy. *Arc*+ neurons were classified as foci-positive (Foci+), cytoplasmic-positive (Cyto+), and double-labeled (Dbl+) using the ImageJ software package. Repeated measures ANOVA showed that there were no significant differences in age or object change treatment (AB) factors. About a third of the cells counted in this layer were active in response to the behavioral treatment overall, and half of these were active in both epochs of behavior, regardless of object identity. The proportion of neurons active in both sessions (Dbl+) was significantly greater than either Foci+ or Cyto+ positive neurons alone. Thus, while half of the responsive cells do show stable activity across behavioral treatment sessions, these cells do not appear to carry information about distinct object identities.

Title: The effects of age and environmental change on Arc transcription in perirhinal cortical ensembles following object exploration

Authors: *S. N. BURKE[1,2], A. L. HARTZELL[1,2], J. P. LISTER[1,2], L. T. HOANG[1,2], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., Univ. Arizona, TUCSON, AZ; [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Object recognition memory requires the perirhinal cortex (PRC) and this cognitive function declines during normal aging. Specifically, old animals are able to retain the memory of a familiar object but they are more likely to falsely recognize a novel stimulus (Burke et al.,

2010). This 'false memory' for novel stimuli observed in aged rats also occurs when the environmental context is changed between the familiarization and test phase of the spontaneous object recognition task. Recent electrophysiological recordings from awake-behaving rats have shown that neurons in the PRC of young rats are activated by 3-dimensional objects (Burke et al., 2012). Thus, it is possible that age-related object recognition deficits could be due to alterations in how PRC neuron activity is modulated by objects in older animals. The present study used cellular compartment analysis of temporal activity by fluorescence *in situ* hybridization (catFISH) with confocal microscopy to monitor subcellular distributions of activity-induced *Arc* RNA in the PRC. Activity was monitored during two distinct epochs of object exploration. In one group of rats (6 young and 6 aged) an animal was placed in a familiar testing arena and was allowed to explore five different 3-dimensional objects for two 5-min sessions separated by a 20-min rest (AA condition). The second group of animals (6 young and 6 aged) explored the same five 3-dimensional objects for two 5-min sessions but the environment was changed between the first and the second epoch of exploration (AB). Behavioral data showed that both young and aged rats spent less time exploring objects during the second epoch of behavior in both conditions, indicating successful object recognition. Interestingly, the reduction in object exploration during the second epoch relative to the first was not associated with reduction of cells that expressed *Arc* between epochs. This indicates that similar populations of neurons are activated by exploring the same objects during two distinct epochs, even when the objects are familiar and the environment changes. When numbers of *Arc* positive neurons were compared between age groups, the old rats had significantly lower proportions of *Arc*-positive PRC neurons for both the AA and AB behavioral conditions. The age-related reduction in the population of PRC neurons that express *Arc* during object exploration could reflect reduced glutamate levels in aged compared to young rats that have been reported for this brain region (Rushaidhi et al., 2012). Together these data support the hypothesis that age-associated functional alterations in the PRC contribute to declines in stimulus recognition over the lifespan.

Title: The influence of advanced age on noradrenergic-dependent novelty detection

Authors: *J. FRIEL[1,2], J. J. FERNG[1,2], A. L. HARTZELL[1,2], S. N. BURKE[1,2], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Previous research has shown that age-associated object recognition deficits are not due to aged rats 'forgetting' a previously experienced stimulus, but because old animals are more likely to identify novel objects as familiar (Burke et al., 2010). The extent that this impairment can be explained by object discrimination problems, or a problem in novelty detection has not been examined. Previous studies have suggested that a functionally intact noradrenergic system is necessary to facilitate novelty detection (Sara et al., 1995). The main source of noradrenaline in the brain, the locus coeruleus (LC), shows several age-associated changes including, altered activity levels (Olphe & Steinmann, 1982; Shirokawa et al., 2000), differences in gene expression (Zhu et al., 2005), and changes in its metabolic pathways (Shirokawa et al., 2003; Matsunaga et la., 2004). The current experiment tested the hypothesis that these alterations in the LC may partially account for the inability of aged rats to correctly respond to novel objects using a task that is known to require noradrenergic activity (Sara et al., 1995). Young (9 months) and old (24 months) rats were placed in a hole board apparatus for a habituation and novel-object detection phase separated by a 3-hour period. The 9 holes of the apparatus were left empty for the habituation phase. In contrast, during the novelty-detection phase the holes were filled with 4 identical objects. Novelty detection was quantified by comparing the number and duration of nose pokes in holes with objects relative to the holes without objects. Because rats were not required to discriminate between novel and familiar objects, this task allows one to measure the ability of animals to detect novelty in the absence of stimulus discrimination requirements. Contrary to the idea that age-related changes in the LC contribute to impairments in object recognition, there was no significant difference in the performance of young and old animals on this task. These data suggest that the decline in the ability of aged rats to appropriately identify novel objects is due to a reduced capacity to discriminate between novel and familiar stimuli, which critically relies on the perirhinal cortex, rather than to an overall decline in LC-dependent novelty detection.

Abstract: Aged animals exhibit a sensitized neuroinflammatory response to a peripheral increase in pro-inflammatory agents relative to adult animals (Abraham et al., 2008; Barrientos et al., 2006, 2009; Chen et al., 2008; Godbout et al., 2005). This increased neuroinflammatory response to peripheral infection occurs in conjunction with hippocampus-dependent learning and memory impairments (Barrientos et al., 2006, 2009). However, the mechanism by which this neuroinflammatory response undermines memory processes in older animals is not understood. The immediate-early gene *Arc* is known to play a critical role in the regulation of synaptic plasticity and long-term memory in the hippocampus (i.e., Guzowski et al., 2000; Plath et al., 2006; Miyashita et al., 2008). Previously, it has been shown that a peripheral *Escherichia coli* infection suppresses basal *Arc* gene expression in the whole hippocampus as measured by RT-PCR, as well as *Arc* gene expression induced by contextual fear conditioning, in the hippocampus of aged rats (Frank et al., 2010). We investigated the effect of peripheral *E. coli* infection on *Arc* expression patterns in individual cell regions within the dorsal hippocampus after contextual fear conditioning in adult and aged rats, using compartmental analysis of temporal activity by fluorescence *in situ* hybridization (catFISH) (Guzowski et al., 1999). This technique permits inferences about the subcellular distribution of *Arc* mRNA based on the activity history of cells. Populations of adult and aged rats were injected with *E. coli* four days before contextual fear conditioning. *Arc* expression patterns revealed that a smaller proportion of granule cells within the dentate gyrus of aged rats express *Arc*, possibly due to changes in methylation status of the Arc gene during aging as suggested by previous studies (Small et al.,

2004; Penner et al., 2011). Additionally, peripheral *E. coli* infection had no effect on the proportion of cells expressing *Arc* in the dentate gyrus in response to contextual fear conditioning in aged or adult animals. This result in conjunction with the finding that peripheral *E. coli* infection suppresses *Arc* gene expression (Frank et al., 2010) suggests that it may reduce the amount of *Arc* mRNA transcribed on an individual cell basis but does not effect the total number of cells transcribing *Arc* in response to contextual fear conditioning in the dentate gyrus. The CA regions are currently under investigation.

Title: Diminished place field density and direction-dependent learning in the aged rat

Authors: *L. A. SCHIMANSKI[1,2], P. LIPA[1,2], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Remembering the locations of specific stimuli within an environment becomes more difficult during senescence. The changes in neural information processing underlying this age deficit are not yet fully understood. In this study, the simultaneous activity of ensembles of hippocampal CA1 principal neurons (‘place cells’) was recorded from 6 young adult (9-12 month) and 6 aged (26-28 month) male F344 rats, while they learned the locations of eye-blink stimuli on a circular track. Rats were trained to run alternating clockwise and counterclockwise laps on this circular track with a barrier at 12 o’clock, where they received food reward. Using electrical stimuli applied to the eyelid, the animals were conditioned to blink at two distinct locations on the track: one eye-blink stimulus location was conditioned in only the clockwise running direction while the other one was only administered in the counterclockwise direction. As reported by Schimanski et al. (2011), young and old rats exhibited equivalent accuracy of the blink response at both conditioned locations, but old rats were less successful in restricting the

blink response to the conditioned running *direction*. Here we examine place field firing properties of young and old pyramidal cells under these conditions in more detail. When the number of place fields identified per CA1 pyramidal cell was measured in both running directions, the aged rats exhibited fewer place fields per cell than did young rats. These data suggest a subtle difference between age groups in how the CA1 'map,' or population code represents the same environmental experience. Moreover, when we applied a random sampling algorithm to the place field data (Monte Carlo method), the outcome showed that the number of bidirectional fields observed in young and old rats was close to what one would expect from 'accidental' overlap of firing in opposite direction trajectories, given the situation that each unidirectional field was randomly positioned to occur in either the clockwise or counterclockwise direction. Taken together, these findings imply that because the number of CA1 place fields per cell is reduced during aging, the number of bidirectionally-active place fields also must decline accordingly. These age-dependent alterations of the population code may contribute to the reduced ability of aged rats to discriminate one running direction from another in learning this location- and direction-dependent version of eye-blink conditioning.

Title: Spiking of theta-firing neurons in medial prefrontal cortex precedes population activity during behavior and rest

Authors: *N. INSEL[1,2], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., Univ. Arizona, Tucson, AZ; [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Neural activity in the medial frontal cortex can become synchronized within a 6-10 Hz "theta" oscillation, which is thought to underlie communication with more posterior brain regions during selection of actions, emotions, or memories. Cortical circuits are made-up of multiple cell types, and the dynamics among these with respect to the theta oscillation are not

well established. We identify a small (1-3%) proportion of neurons, recorded primarily from dorsal anterior cingulate and dorsal prelimbic cortices, which exhibit regular bursts of action potentials at theta frequency. Action potentials in these neurons had shorter peak-to-trough latencies compared with averages across the populations of regular- and burst-firing neurons, but they were wider than fast-spiking neurons. When rats performed a decision task, theta-firing was coherent with local field potentials recorded from the dorsal hippocampus, with burst intervals averaging 8.4 Hz. During rest epochs, theta-firing was observed in a largely-overlapping set of neurons, and average burst intervals were reduced to approximately 7.5 Hz. Cross correlations revealed that activity among theta-firing neurons preceded activity in fast-spiking and regular-firing neurons by tens of milliseconds. Theta-firing neuron activity also appeared to precede increases in theta-frequency bursting among other burst-firing neurons. Individual theta-firing neurons were selective for trial phases and session epochs; on average, however, these neurons were most active during the choice phase of a decision task. Neither trial phase nor session epoch influenced the temporal relationships between theta-firing neurons and other neurons in the population. One interpretation of these data is that theta-firing neurons represent a specific component of the cortical circuit that are the first to respond to presynaptic regions oscillating at the theta frequency, and may contribute themselves to local theta synchronization. If they do play a role in synchronization, then the observation that each neuron exhibits specific selectivity patterns may indicate that increased network synchronization reflects increased numbers of theta-firing neurons becoming active, as opposed to graded changes across all theta-firing neurons.

Title: Grey matter volume in the orbital prefrontal cortex correlates with reinforcer devaluation but not reversal learning performance in bonnet macaques

Authors: *K. PLANGE[1,2], S. N. BURKE[1,2], A. THOME[1,2], J. R. ENGLE[1,2], T. P. TROUARD[3], K. M. GOTHARD[4], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., Univ. Arizona, TUCSON, AZ; [2]ARL Div. of Neural Systems, Memory & Aging, [3]Dept. of Physics, [4]Dept. of Physiol. and Col. of Med., Univ. of Arizona, Tucson, AZ

Abstract: Behaviors that rely on the prefrontal cortex are particularly vulnerable to the process of normal aging, but the neurobiological changes that occur over the lifespan in the different subregions of this brain structure are not completely understood. In the current experiment, young (n = 7) and aged (n = 9) bonnet macaques were trained on reversal learning and reinforcer devaluation tasks using a Wisconsin General Testing Apparatus. The reinforcer devaluation task tests the degree to which response selection can be guided by reward value, by pairing two different food rewards (food 1 and food 2) with distinct sets of objects. Monkeys learn this association over weeks and are then satiated on food 1. Successful performance occurs when the animal selects the objects associated with the non-satiated food 2. In contrast, reversal learning tests an animal's ability to learn that a previously rewarded stimulus is no longer associated with a reward on an object discrimination task. Data from lesion studies suggest that the orbital prefrontal cortex (OFC) is necessary for successful performance on both of these tasks (e.g., Gallagher et al., 1999; Bohn et al., 2003). To assess the extent that OFC structural integrity predicts performance on these two tasks, anatomical MRIs were obtained from 7 young and 6 aged monkeys that had completed both behavioral conditions. Boundaries of the OFC were manually determined by three independent observers blind to the age and behavioral performance of the animal (high inter-rater reliability was obtained for all comparisons, $r_{[12]} > 0.7$, $p < 0.01$). Although as a group the aged monkeys performed significantly worse than did young animals on both the reinforcer devaluation ($T_{[14]} = 2.07$, $p < 0.05$) and the reversal learning tasks ($T_{[14]} = 3.80$, $p < 0.01$), there was no significant difference in total OFC volume between age groups ($T_{[12]} = 0.88$, $p = 0.15$). While there was no significant correlation between OFC volume and reversal learning performance ($r_{[12]} = -0.22$, $p = 0.46$), a significant correlation was found between OFC volume and performance on the reinforcer devaluation task ($R_{[12]} = 0.61$, $p < 0.05$). Together these data suggest that OFC grey matter volume is associated with an animal's ability to guide its behavior based on predicted reward value, but not to reverse a previously learned association. Because reinforcer devaluation performance requires functional connectivity between the amygdala and the OFC (Baxter et al., 2000), these data suggest that alterations in structural integrity of the OFC may be involved in defective communication between these two brain structures, which disrupts an animal's ability to use reward value to guide behavior.

Title: Senescence modifies the structure of information encoding in the medial temporal lobe

Authors: *A. THOME[1,2], P. LIPA[1,2], C. A. ERICKSON[1], C. A. BARNES[1,2]
[1]Evelyn F. McKnight Brain Inst., Univ. Arizona, TUCSON, AZ; [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ

Abstract: Primates are remarkably adept at categorizing and remembering visual objects. The ability for organisms to discriminate and recall previously encountered information is critically dependent on the integrity of the medial temporal lobe (MTL) and inferior temporal cortex (ITC) (e.g., Mahut et al., 1982; Zola-Morgan et al., 1994; Buffalo et al., 2000). Lesions of these structures produce profound deficits on a variety of recognition memory and perceptual discrimination tasks. Data across a number of species indicate that these processes are similarly disrupted in senescence (e.g., Moss et al., 1988; Burke et al., 2011). However, the neural mechanisms underlying age-related deficits are poorly understood.
Information processing in the ventral visual stream is believed to proceed along a hierarchy of association, in which the responses in one region reflect the conjunctions of stimulus features represented discretely in upstream cortical areas (e.g., Barlow, 1961; Mishkin et al., 1983). Single-unit recording studies in primates have demonstrated that neurons in these regions represent information via population codes (e.g., Tanaka et al., 1991; Gross, 1992; Logothetis et al., 1995). However, the stability of a population code rests on the reliability of the responses of individual neurons. One theory of cognitive aging proposes that deficits in perceptual discrimination may be tied to deficits in sensory processing (e.g., Baltes and Lindenberger, 1997; Li and Lindenberger, 2002). Selective degradation of sensory information in lower level sensory areas may result in instability of information representation in higher level association areas. A number of theoretical and empirical findings now indicate that behavioral accuracy may rely on the stability of these responses.
To test this hypothesis we recorded the activity of 1633 units from 2 old and 3 young chronically implanted rhesus macaques (*macaca mulatta*) during two different visual tasks. A variety of

analytical techniques were used to examine the tuning characteristics on individual neurons, as well as the underlying signal to noise ratio. These data show that in aged animals there exists a significant decrease in quality of information encoding across the hippocampus (CA3/CA1) as well as upstream cortical structures (EC/PRC/TF). These results provide not only validation of a number of theoretical proposals and behavioral results, but further open new avenues for the development of cognitive and therapeutic approaches.

Title: Mapping the spatial navigation network of young and aged rhesus macaque monkeys: A positron emission tomography study.

Authors: *J. R. ENGLE[1,3], C. J. MACHADO[3], A. P. MAURER[1,2], M. PERMENTER[3], J. VOGT[3], C. A. BARNES[1,2,3]
[1]Evelyn F. McKnight Brain Inst., [2]ARL Div. of Neural Systems, Memory & Aging, Univ. of Arizona, Tucson, AZ; [3]California Natl. Primate Res. Ctr., Davis, CA

Abstract: Activation of the neural substrates devoted to spatial navigation is largely dependent upon behavioral and environmental cues. Much of our current understanding of how such cues engage these neural substrates comes from studies of freely moving rodents, as it is technically more difficult to study this problem in the nonhuman primate brain. To gain a better understanding of nonhuman primate spatial navigation networks and how they change with age, four rhesus monkeys were trained to freely or passively traverse a long enclosure, and to walk on a treadmill. We measured cerebral glucose metabolism with the radiotracer 2-deoxy-2[^{18}F]-fluoro-D-glucose (FDG) and high-resolution positron emission tomography (microPET). Two of the four monkeys have been successfully scanned after the four conditions given in

pseudorandom order: 1) freely traversing the enclosure, 2) passive traversals in the same enclosure not excluding optic flow, 3) walking on a treadmill without optic flow, 4) sitting in a cage (control condition). We used ROI analysis to assess the contributions of behavioral state and age on spatial navigation network activity. Our preliminary results from two monkeys (12 and 27 years old) suggest that ROIs in the right hemisphere overall had a significantly greater uptake of FDG than ROIs in the left hemisphere (t-test, $p < .001$). The magnitude of the percent change across the behavior conditions, however, interacted with age. The difference in FDG uptake compared to the control condition was more pronounced when the young monkey was considered separately, although movement behavior was matched across age. This interaction was found in the right medial temporal lobe, area TE, anterior cingulate, retrosplenial and medial occipitoparietal area ROIs. These preliminary results suggest that the right hemisphere of the rhesus monkey may contribute to spatial navigation, and may undergo similar age-related changes in the spatial navigation network that has been reported in aged rodents.

Title: Age-related changes in spatial pattern separation in rats

Authors: *E. I. GRACIAN[1], L. E. SHELLEY[2], A. MORRIS[3], A. NAJJAR[2], P. E. GILBERT[4]
[1]Psychology, [2]Dept. of Psychology, San Diego State Univ., San Diego, CA; [3]Ctr. for the Neurobio. of Learning and Memory, Univ. of California, Irvine, Irvine, CA; [4]UCSD-SDSU Joint Doctoral Program in Clin. Psychology, San Diego, CA

Abstract: Pattern separation is described as a mechanism for separating partially overlapping patterns of activation so that one pattern may be retrieved as separate from other patterns. Recent studies have reported that spatial pattern separation may be impaired in older adults; however, little is known about age-related changes in spatial pattern separation in rats. Therefore, the current study tested young and old Fischer/Brown Norway rats 6 mo ($n = 18$) and 24 mo ($n = 18$) of age on a task shown to be dependent on the DG subregion of the hippocampus (Morris et al., 2012). Each rat was randomly assigned to an adjacent or a separate condition and tested on a

place-learning task using a radial eight-arm maze (McDonald & White, 1995). Rats were trained to discriminate between a reward arm and a non-reward arm that either were adjacent to one another (high interference/ high demand on pattern separation) or separated by a distance of two arm positions (low interference/ low demand on pattern separation). Each rat received 10 trials per day and was tested until the animal reached a criterion of nine correct choices out of 10 consecutive trials across two consecutive days of testing. The results did not reveal significant differences between young and old rats in the number of trials required to reach the learning criterion in the adjacent or separate condition. However, rats required significantly more trials to reach the learning criterion in the adjacent condition compared to the separate condition. An examination of the total errors committed before reaching the learning criterion revealed that old rats make significantly more errors than young rats. In addition, more errors were committed in the adjacent condition than the separate condition. In the adjacent condition, there may be high overlap among the external cues associated with the non-reward and reward arms, potentially requiring more pattern separation due to heightened interference. In contrast, there likely is less interference among the external cues in the separate condition resulting in less need for pattern separation. The results suggest that spatial pattern separation may be less efficient in old rats and are consistent with recent human studies.

Title: Somatostatin-positive interneuron loss in the aged memory-impaired rat dentate hilus

Authors: *A. M. SPIEGEL, M. GALLAGHER
Dept of Psych & Brain Sci., Johns Hopkins Univ., BALTIMORE, MD

Abstract: Accumulating evidence indicates that a failure to maintain balance in excitatory and inhibitory processes is a central component of memory loss associated with aging and Alzheimer’s disease (AD) in humans. Studies examining individuals with mild cognitive impairment or others at risk for AD show increased activation in the hippocampus that is localized to the denate gyrus/CA3 subregions. Similarly, patterns of aberrant hippocampal

activity occur in a memory-impaired subgroup of a rodent model of neurocognitive aging. In this model aged Long Evans rats exhibit stable individual differences in cognitive outcomes, similar to humans, when trained on a hippocampus dependent spatial memory task. In aged impaired animals, increased activity of the DG/CA3 network correlates with impaired pattern separation function, resulting in an inability to rapidly encode new information. It is postulated that a decline in inhibitory control within the aged hippocampus may contribute to excess activation in the network. In support of that idea, we have shown that memory impairment in the aged Long Evans rat is associated with a specific reduction in hilar interneuron integrity (Spiegel & Gallagher, SFN 2011). The hilus contains a functionally heterogeneous population of interneurons providing one of the strongest inhibitory controls over principal cell activity found in any cortical region. Given this diversity, identifying the integrity of specific subpopulations of hilar interneurons in conditions of cognitive impairment is important for understanding what components of this inhibitory circuitry are most susceptible to the effects of aging. Somatostatin (SOM) and Neuropeptide Y (NPY) expressing hilar interneuron subgroups regulate granule cell excitability at the perforant path termination zone and contribute to pattern separation processes. We studied the condition of NPY- and SOM-immunoreactive interneurons in relation to cognitive status in behaviorally characterized young and aged Long Evans rats. Using immunohistochemistry with stereological quantification, we found that SOM-positive hilar interneurons were reduced in aged rats with memory impairment relative to both young adults and aged cohorts with intact cognitive function, while NPY-positive hilar interneuron number did not differ between young and aged rats. These data coincide with evidence from models of AD and risk for AD, (e.g. carriers of apoE4) which also demonstrate early decline in SOM positive interneurons. Together these data highlight the importance of SOM-positive hilar interneurons in maintaining proper memory function and inhibitory processing in the aged hippocampus.

Title: Declines in social interaction and social recognition memory are associated with deficits in synaptic plasticity in aged mice

Authors: *X. S. XIE[1], L. YANG[2], B. ZOU[2], C. PASCUAL[2], A. MALIK[2], J. XIE[2]
[1]Afasci Res. Laboratory, Afasci, Inc., Redwood City, ; [2]Afasci Res. Laboratory, Afasci, Inc., Redwood City, CA

Abstract: Social withdrawal and decline of social recognition memory manifest with aging in humans. Here we tested the hypothesis that aged mice display decreases in social interaction and social recognition memory are associated with deficits in hippocampal synaptic plasticity.
Social cues (strange mice taken from different homecages) were introduced to the test mice (3-4 month old vs 12-14 month old, female, n=8) in a homecage after habituation. Time spent for investigation of each social cue was automatically quantified using the SmartCage™ (AfaSci, Inc). Direct contact social test with a social cue was conducted using manual scoring. Field synaptic potential was recorded in CA1 and dentate gyrus (DG) of hippocampal slices from the young and aged mice.
In the automated social interaction test, aged mice spent significantly less time interacting with stranger 1, indicating a lack of sociability, although their social novelty preferences to the stranger 2 were comparable to young mice. However, if the social novelty test was delayed in 10 min, the social novelty preference disappeared in aged mice. In contrast, young mice recognized the Stranger 1 for at least 1 h and disappeared in 24 h. Moreover, the aged mice could not recognize their littermates after separation for 20 min, while young mice retention was up to 24 h. In the direct contact test, aged mice spent significantly less time interacting with strangers compared to young mice. Their social recognition retention in this direct contact setting disappeared in 3 h, whereas young mice preserved in 3 h and disappeared in 24 h.
The input-out curves and population spike in CA1 area was significantly lower (1.4 ± 0.1mV, mean ± SEM, in old vs 3.7 ± 0.6mV in young,), and paired-pulse facilitation was significantly less in DG (123.3 ± 4.8% in old vs. 259.6 ± 22.1% in young). Long-term potentiation (LTP) could not be induced in DG of old mice (103.5 ± 14.9% of baseline), while the amplitude of population spike in the young DG increased to 217.7 ± 46.8% of baseline at 45 min after two trains of 100 Hz stimulation. These results indicate that aging significantly decreases social interaction and social recognition memory, and is associated with deficits in basal synaptic neurotransmission and plasticity in the hippocampus.

Title: Hippocampal transcriptomic analysis provides insight into molecular mechanisms of physiological and cognitive brain aging

Authors: *W. M. FREEMAN[1], H. D. VANGUILDER STARKEY[2], G. V. BIXLER[1], J. A. FARLEY[3], H. YAN[3], W. E. SONNTAG[3]
[1]Pharmacol., [2]Dept. of Pharmacol., Penn State Col. of Med., Hershey, PA; [3]Reynolds Oklahoma Ctr. on Aging, Univ. of Oklahoma Hlth. Sci. Ctr., Oklahoma City, OK

Abstract: In both humans and animal model organisms, advanced brain aging is accompanied by molecular alterations that represent impairment of processes ranging from metabolism to inflammation to synaptic signaling. Deficits of hippocampal spatial learning and memory are also evident in a subset (~50%) of subjects, although not all age-related changes in cellular and molecular function are associated with cognitive impairment. The goal of this study was to comprehensively compare and contrast age-related and cognitive decline-specific molecular changes that occur in the hippocampus at both the cellular and synaptic levels. Rats were assessed for spatial learning and memory performance by Morris water maze testing before sacrifice. Whole-genome gene expression analysis was performed to define the transcriptome of hippocampal synaptic preparations, subregion dissections (CA1, CA3, DG), and whole, unfractionated hippocampus derived from mature adult (12m) and aged (24-26m) Fischer 344 x Brown Norway hybrid rats. This evaluation enabled classification of aged rats as cognitively intact or cognitively impaired relative to adult group performance. As expected, fewer transcriptomic alterations were observed specifically with cognitive impairment than with aging, and substantial commonality was evident between expression changes in CA1 and CA3. Meta-analysis of the resultant data demonstrates that transcripts indicative of glial activation (*e.g.*, inflammation and immune-response pathways) are induced across hippocampal subregions with advanced aging and are not directly associated with deficits of spatial learning and memory. Markers of complement activation and STAT3 signaling are induced with aging in pyramidal cell-containing regions (CA1 and CA3) to a greater extent than in the granule cell-containing dentate gyrus (DG). Distal (synaptosome) mRNA changes associated with advanced aging include downregulation of neurotransmission-related and upregulation of antigen presentation-

related genes, whereas whole hippocampal changes recapitulated the neuroimmune activation evident in subregion analyses. Smaller numbers of gene expression changes were associated specifically with cognitive deficits, and included transcripts for growth factor signaling, transcription regulation, and protein modification. Interestingly, the direction of expression change often differed between CA1/CA3 and DG. These studies indicate a potentially additive process of age-related neuroimmune activation and impaired neurotransmission that combine with cognitive impairment-specific inhibition of neuronal maintenance and synaptic plasticity.

Title: Blockade of NK3-receptors interacts with Senktide-mediated behavioral effects and ACh release in aged rats

Authors: S. SCHÄBLE, *J. P. HUSTON, A. M. DE SOUZA SILVA
Univ. of Düsseldorf, Düsseldorf, Germany

Abstract: NK3-receptors (NK3-R) have been localized in brain regions which have been implicated in processes related with learning and memory, including the frontal cortex, hippocampus, amygdala and medial septum in rats and mice. Previous studies displayed that administration of the NK3 receptor agonist senktide promoted both age-dependent and pharmacological-induced memory deficits. There is also evidence that senktide increased ACh release in aged rats. Given the profound effects of NK3-receptor activation on behaviour and cholinergic activity of the basal forebrain, we examined whether NK3-receptors mediate learning and memory processes and whether cholinergic mechanism underlie these effects. Our aim in this study was to assess the effects of systemic administration of the NK3-R antagonist SR142801 (3 mg/kg or 6 mg/kg) on NK3-R activation by senktide (0.2 mg/kg) in the object-place recognition and water maze task in aged Wistar rats (17 months old). Thereafter, the aged animals were submitted to the in vivo microdialysis procedure with HPLC to evaluate the effect of these treatments on ACh levels in frontal cortex, amygdala and hippocampus.
Results: Senktide (0.2 mg/kg) was found to reinstate age-dependent deficits in object-place

recognition task and to enhance water-maze learning. Application of 6 mg/kg of the NK3-R antagonist, SR142801, blocked these memory-enhancing effects of senktide in the aged animals. Blockade of NK3-receptors by 6 mg/kg SR142801 diminished the senktide-induced increase in ACh neurotransmission in the frontal cortex, amygdala and hippocampus.
Our results indicate that the behavioral performance within the object-place recognition and water maze task affected by senktide treatment seems to be directly mediated via the NK3-receptors. In summary, these results provide further insight into behavioral and neurochemical functions of the NK3-R in learning and memory processes in aged rats.

Title: Effects of the novel histone deacetylase inhibitor, EVX001688, on synaptic connectivity in young and aged rats.

Authors: *A. S. SEWAL[1,2], H. PATZKE[3], E. J. PEREZ[1], P. PARK[1], W. DRIWECH[1], P. R. RAPP[1]

Abstract: Previous reports indicate that treatments targeting epigenetic regulation, such as histone deacetylase (HDAC) inhibitor administration, can enhance hippocampus-dependent memory and synaptic connectivity. HDAC inhibition prolongs histone acetylation, inducing a permissive environment for the transcription of genes critical for memory and synaptic plasticity. Here we evaluated the effect of the histone deacetylase inhibitor (HDACi) EVX001688 on synaptic markers in the hippocampus of young (7-9 months; veh n=4; drug n=6) and aged (26-28 months; veh n=7; drug n=7) male F344 x BN rats. We also tested whether HDACi mediated changes in synaptic connectivity are regionally selective across the principal connectional zones of the hippocampus: CA1 stratum radiatum, CA3 stratum lucidum and stratum radiatum, and laminar subdivisions of the dorsal dentate gyrus molecular layer. EVX001688 is brain-penetrant and inhibits a spectrum of HDACs, selective for classes I, IIb, and IV in the nanomolar range.

Rats received a single injection (i.p.) of vehicle or 30mg/kg of drug 90 minutes before sacrifice - a dose we previously demonstrated yields modest improvement in long-term spatial memory in young and aged rats. Histone H4 acetylation was robustly increased across all hippocampal principal cell layers in both young and aged subjects, confirming the efficacy of HDACi treatment. Selected synaptic markers, including pre-, post-, and intrajunctional proteins (synaptophysin, spinophilin, and N-cadherin) were analyzed by quantifying regional immunofluorescence labeling intensity. Under resting, baseline conditions at 90 minutes post-treatment, no drug effect was detected on synaptic protein levels in the young or aged hippocampus. Experiments currently in progress are designed to test the prediction that the reported effects of HDAC inhibition on connectivity are instead mediated by a permissive mechanism that requires concurrent memory-related neural signaling in the hippocampus.

Title: A fine balance: Regulation of Arc/Arg3.1 transcription and translation in a model of normal cognitive aging.

Authors: *B. R. FLETCHER[1], M. GALLAGHER[2], M. L. SHAPIRO[3], P. R. RAPP[1]
[1]Lab. of Exptl. Gerontology, Natl. Inst. Aging, BALTIMORE, MD; [2]Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD; [3]Fishberg Dept. of Neurosci., Mount Sinai Sch. of Med., New York, NY

Abstract: Age-related cognitive decline is thought to arise from a constellation of neuronal alterations including changes in structure, connectivity and cellular plasticity mechanisms. We examined both behaviorally induced transcription and translation of the immediate early gene Arc in relation to chronological and cognitive aging. Spatial learning capacity was used to classify aged rats as either impaired (AI) or unimpaired (AU) relative to young adults. Several weeks later rats were tested in a redundant place-cue (RPC) version of the water maze and

sacrificed either 30 or 120 minutes post-training, i.e., at timepoints appropriate for assessing behaviorally induced Arc transcription and translation, respectively. RPC training in young adult and AU rats led to significantly increased Arc mRNA transcription in the hippocampus relative to baseline control levels. Arc transcription in the hippocampus of trained AI rats, in contrast, failed to exceed baseline control values. Next we examined Arc protein by quantitative western blotting to determine if the blunted behavioral induction of Arc mRNA in AI rats is associated with correspondingly low protein levels. Surprisingly, behaviorally induced increases in Arc protein were preserved in both CA1 and CA3 in AI rats. We then examined known regulators of Arc translation as a potential basis for this unexpected sparing. Whereas phosphorylation of elongation factor 2 (EF2) was increased by behavioral training in CA1 and CA3 in all groups, the increase was significantly greater in CA1 of AI rats relative to young adults, suggesting that the increase in Arc protein relative to mRNA may be mediated in part by an increase in the rate of elongation. We also found that eIF4A3 - a protein known to regulate Arc mRNA stability - is significantly increased in CA3 and CA1 after behavioral testing in young and AU rats, but not among AI animals. Decreased eIF4A3 could directly contribute to the increase in Arc protein relative to mRNA seen in the AI hippocampus by allowing additional rounds of translation to occur before the mRNA transcript is degraded. These findings indicate that compensatory changes in translational regulation result in maintained behavioral induction of Arc protein in AI rats that are nonetheless insufficient to support normal learning and memory. By this view impairment may arise from a decrement in the fine spatial and temporal regulation of Arc translation that is critical for its proper function in synaptic plasticity.

Title: Behavioral effects of progranulin loss on a transgenic mouse model through aging

Authors: *C. VOLLERT[1], K. NGO[1], H. POURGARZHAM[1], G. L. GERTON[2], J. ERIKSEN[1]
[1]Pharmacol. and Pharmaceut. Sci., Univ. of Houston, Houston, TX; [2]Ctr. for Res. on Reproduction and Women's Hlth., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Frontotemporal dementia (FTD) is the second most common cause of pre-senile dementia in patients under the age of 65. Recent evidence has shown that mutations in the human GRN gene are associated with frontotemporal lobar dementia with ubiquitinated TDP-43 inclusions, resulting in only one functional allele. This evidence suggests that a global reduction in eitherexpressed or secreted levels of progranulin (PGRN) is important in the etiology of dementia. Despite growing interest in the role of pgrn in dementia and the central nervous system, there have been few studies characterizing the behavioral effects of PGRN haploinsufficiency. In this study, 6, 12, and 24 month old PGRN haploinsufficientmice were subjected to a battery of behavioral tests and evaluated for the effect of PGRN loss on activity, anxiety, motor performance, and memory.

Title: Hormone treatment and fine motor skill learning in middle-aged rats

Authors: N.-V. DANG[1], A. N. GARCIA[2], T. A. JONES[3], A. C. GORE[4], *W. YIN[5]
[1]Col. of Pharm., [2]Psychology Dept., [3]Psychology Dept. and Inst. for Neurosci., [4]Col. of Pharmacy, Inst. for Cell. and Mol. Biol. and Inst. for Neurosci., Univ. of Texas at Austin, Austin, TX; [5]Col. of Pharmacy, Univ. of Texas at Austin, Austin, TX

Abstract: During menopause, decreasing levels of estradiol have been shown to affect numerous neurobiological functions, but relatively little is known about motor functions. Estrogen receptors are distributed in the motor cortex and in cells projecting to the motor cortex. Dramatic changes of estradiol in menopause could therefore change synaptic plasticity in the motor cortex and the motor cortical network, and have detrimental effects on motor skill learning ability. Our study sought to evaluate the effects of hormone treatment on fine motor skill learning. Using a forearm reaching motor skill task in which rats are trained to reach through a narrow slot to retrieve a food pellet, we measured the fine motor skill learning ability in middle-aged Sprague-Dawley female rats after estradiol treatment. The potential cognitive, motivational and bodyweight changes related to aging and estradiol treatment were also monitored. All rats were

ovariectomized (OVX) and received estradiol or vehicle capsule during the surgery at 11 months-old. After 3 months, capsules were either exchanged, removed or continued to accomplish different timings and durations of hormone treatment. This resulted in four groups, described from the time of OVX: 1) 3 months estradiol followed by vehicle; 2) 3 months vehicle followed by estradiol; 3) continuous estradiol; 4) continuous vehicle. Forearm reaching motor learning tests were performed at 15 months of age. A total of 30 sugar pellets were given in one session of forearm reaching test per day for three weeks. We found that at early stages of motor skill learning, rats with continuous vehicle treatment (group 4) had the lowest success rates, while rats given estradiol capsules, whether constantly, introduced later, or removed later, had comparable success rates. At later learning stages, the success rate between groups converged. We also noticed that a high percentage of rats would not participate the training with vehicle treatment either constantly or introduced later even though they eat all pellets in their home cage and from the floor of training cage. In addition, we found dramatic effects of timing and duration of estradiol treatment on bodyweight changes. Our data suggest that 1) estradiol treatment facilitates early stage of fine motor skill learning. 2) With continuous motor skill training, rats can reach comparable success rates with or without estradiol treatment. 3) Motivation of fine motor skill learning decreased without estradiol treatment.

Title: Learning generalization within and across sensory modalities in a mouse model

Authors: *A. T. POPESCU, A. KANG, J. TAO, M. R. ZHOU, H. E. TAN, M.-M. POO
MCB, UC Berkeley, Berkeley, CA

Abstract: Although the phenomenon of learning transfer has been described and characterized in different forms, the neural circuit basis remains largely unknown. Here, we attempt to uncover the neural mechanisms in a mouse model of stimulus discrimination. Specifically, we compared learning transfer between consecutive tasks using stimuli within or across sensory modalities. Mice were trained to discriminate two stimuli (either two different sounds or two visual stimuli,

one second in duration), and learned that licking right after one of them (conditioned stimulus - CS+) resulted in water delivery while the other stimulus had no effect (non-conditioned stimulus - CS-). Performance on this task was measured as percent of CS+ presentations followed by successful reward delivery. A discrimination score was also calculated based on anticipatory licking during the stimuli presentations. Both performance and stimulus discrimination increased consistently over the ten days of training, reaching stable values within five sessions. After ten days, animals started a similar discrimination task with stimuli either in the same or a different sensory modality. We observed different forms of learning generalization: the new stimulus-response acquisition for same modality tasks was almost instantaneous, leading to a significant difference between the two tasks (p<0.0001, n=11). Similarly, discrimination between the new stimuli was acquired faster compared to the first set (p=0.001, n=11). These effects were not observed when the new stimuli were in a different sensory modality (visual-to-auditory, or auditory-to-visual): stimulus-response acquisition occurred at a similar rate (p=0.15, n=8), and discrimination for the second set of stimuli was in fact impaired (p=0.022, n=8). Dopamine D1 receptor antagonist SCH-23390 injected in the medial prefrontal cortex (mPFC) impaired discrimination learning, but not stimulus-response acquisition. Animals that received SCH-23390 injections in mPFC during training on the first task (n=6) learned to discriminate the second, cross-modal set of stimuli much better than controls (p=0.016). This indicates that learning stimulus-discrimination in one sensory modality hinders learning the same task in a different modality, and that dopamine signaling in mPFC plays a crucial part in this process. Ongoing voltametry recordings and optogenetic experiments suggest that dopamine fluctuations in the mPFC are important for acquiring, but not performing the stimulus discrimination.

Title: CA1 specific deletion of P/Q type calcium channel alters spatial representation of place cells.

Authors: *J. CHO[1,2], D. JUNG[1,2], H. SHIN[1]
[1]KIST, Seoul, Korea, Republic of; [2]Univ. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: Voltage-gated Calcium Channels, VGCCs, play a key role in transmitting signals between neurons, involving in different cellular functions such as cell to cell communications, and the regulation of certain genes etc. Specifically, it has been implicated with modulatory effect on spatial memory in the hippocampal pyramidal neurons. Although P/Q type calcium channel has been well studied on modulating signal transmission and synaptic plasticity in the cerebellum, neither cellular mechanism nor effect on the hippocampal place cell activity has yet been investigated. The hippocampal pyramidal cells are characterized by its increased firing rate at a specific location and its burst spike known as complex spiking. In addition, it recently has been reported that the temporal properties of spiking pattern of the pyramidal cells modulate the place cell behavior in relation with spatial memory. Therefore, we examined place cell properties of CA1 pyramidal cells in hippocampus of mice with CA1 selective deletion of Cav2.1 P/Q type calcium channel to investigate its role for spatial representation of place cells. We conducted single unit recordings of CA1 pyramidal cells in an open-field arena with a local cue for 2 consecutive sessions, interrupted by a 30-minute interval. The result showed that similarity of the place fields between the two sessions tended to be reduced in the conditional knock-out mice compared to the control mice whereas other spatial information including selectivity and coherence was not significantly different. Moreover, the place fields formed during the first session were remapped in the second session more often in the knock-out mice group, suggesting that spatial representation of place cells of the knock-out mice were less stable compared to the control group.

Title: Phase-Amplitude coupling in rat orbitofrontal cortex discriminates between stimuli predicting reward and aversive outcome during associative learning

Authors: *M. VAN WINGERDEN[1,2], R. VAN DER MEIJ[3], E. MARIS[3], C. M. A. PENNARTZ[2]
[1]Inst. for Exptl. Psychology, Heinrich-Heine Univ. Düsseldorf, Düsseldorf, Germany; [2]Ctr. for

Neurosci., Univ. of Amsterdam, Amsterdam, Netherlands; [3]Ctr. for Cognition, Donders Inst. for Brain, Cognition and Behaviour, Nijmegen, Netherlands

Abstract: The orbitofrontal cortex (OFC) plays a key role in the adjustment of ongoing behavior guided by stimuli in the external world and an animals' current motivational state. It is thought to fulfill this role, at least in part, by representing the outcome associated with single cues or cue configurations. However, lacking efferents to primary motor structures, OFC can only indirectly influence ongoing behavior. It is hypothesized that OFC transmits outcome-predicting value information to target cortical and subcortical structures where it could be used to modify stimulus-outcome, action-outcome or stimulus-action mappings.
Efficient cross-structural communication requires a mechanism by which the excitability of structures involved in the transfer of information is synchronized. Rhythmic mass activity as observed in the extracellularly recorded local field potentials (LFP) exhibits oscillatory patterns in different frequency bands that covary with neuronal excitability and can become coherent with LFP rhythms in remote structures, especially in low-frequency bands. Interactions between lower and higher oscillatory frequencies have been found in the form of phase-amplitude coupling (PAC) where the phase of slower oscillations, reflecting general excitability of networks, modulates the amplitude of high-frequent oscillations.
Here, we present data indicating that PAC occurs between theta and gamma band frequencies in LFPs recorded from rat OFC. Preferentially during the odor sampling phase of a 2-odor Go/NoGo task, PAC magnitude reached peak values, both for stimuli predicting positive outcome (S+) and negative outcome (S-). However, PAC magnitude on S+ trials was significantly higher than on False Alarm trials (S- Go trials), but not Correct Rejections (S- NoGo trials). When examined over trials within sessions, we found that PAC magnitude correlated with learning in both S+ and S- trials, with PAC magnitude on S+ trials leading S- trials. Importantly, the increase of PAC magnitude was not confounded with theta power, which did not systematically increase with trial number.
These results suggest that PAC could function as a general mechanism for retrieving stimulus-outcome associations in OFC during stimulus sampling and possibly in disseminating the associative value of cues to target structures.

Title: How emotional conditions modulate ventral and dorsal hippocampal place cell firing?

Authors: *E. G. WANN[1], T. J. DU[1], S. STEAD[2], I. MUZZIO[1]
[1]Univ. of Pennsylvania Dept. of Psychology, Philadelphia, PA; [2]Mayo Clin., Rochester, MN

Abstract: Lesion and neuroanatomical studies indicate that the dorsal hippocampus specializes in spatial processing while the ventral hippocampus is more involved in emotion and olfaction. Despite these dissimilarities, it is currently unclear how ventral hippocampal neurons respond to different kinds of stimuli, including stimuli of high emotional valance. In vivo studies from ventral area CA3 demonstrate that the scaling of place fields increases as a continuum from the dorsal to the ventral pole of the hippocampus (Kjelstrup et al., 2008; Royer et al., 2010). However, it remains unclear how sensitive these large, non-sparse ventral fields are to visuospatial changes in the environment. Moreover, with the exception of visuospatial cues, cellular responses to the different sensory modalities comprising space have not been thoroughly studied. To characterize the firing patterns along the longitudinal axis, we conducted chronic single unit recordings from area CA1 in the dorsal proximal, dorsal distal, or ventral hippocampus while mice were exposed to a variety of visual and olfactory stimuli, a subset of which varied in emotional valence. Consistent with previous observations, we report that ventral cell representations are larger than those of the dorsal area. Importantly, we also found that a subset of these large ventral fields is very sensitive to visuospatial changes in the environment. In anxiogenic contexts, the in-field firing rates of dorsal cells increase, whereas those of ventral cells decrease. Because olfactory inputs are differentially distributed along the longitudinal axis, we also tested cellular responses to odorants of different emotional valence. Ventral cells display more global remapping than dorsal cells in the presence of an odor, especially when the odor presented has negative valence. In addition to remapping, ventral fields are reduced while dorsal fields expanded in the presence of an aversive odor. These results indicate that cells in the ventral hippocampus are heterogeneous in their sensitivity to spatial cues but most cells are dramatically altered in aversive conditions regardless of whether they are spatially tuned or not.

Title: Hippocampal CA1 place cell properties and high-frequency oscillations during spatial navigation in Arc/Arg3.1 knockout-mice

Authors: *H. A. MALKKI[1], P. MERTENS[1], F. VAN SCHALKWIJK[1], L. A. B. DONGA[1], J. LANKELMA[1], F. P. BATTAGLIA[1], C. MAHLKE[2], D. KUHL[3], C. M. A. PENNARTZ[1]
[1]SILS Ctr. for Neurosci., Cognitive and Systems Neuroscience, Univ. of Amsterdam, Amsterdam, Netherlands; [2]NeuroCure Cluster of Excellence, Charité - Universitätsmedizin, Berlin, Germany; [3]Inst. of Mol. and Cell. Cognition, Ctr. for Mol. Neurobio. (ZMNH), Univ. Med. Ctr. Hamburg - Eppendorf, Hamburg, Germany

Abstract: Arc/Arg3.1 is an immediate early gene that has a dual role as a regulator of AMPA receptor trafficking and actin polymerization. In humans, increased Arc mRNA levels have been linked to Alzheimer's disease, Angelman syndrome and Prader-Willi syndrome, whereas decreased levels are present in certain heritable forms of autism. Furthermore, Arc mRNA levels are altered in mouse models of Alzheimer's disease and Fragile X.
Arc/Arg3.1 has been shown to be crucial for maintenance of long-term synaptic plasticity. Interestingly, short term memory of Arc/Arg3.1 knock-out mice appears intact, but they have severe deficits in long-term memory, suggesting Arc/Arg3.1 to be essential for memory consolidation.
Previous studies have shown that Arc/Arg3.1 is enriched in hippocampal pyramidal neurons and it is rapidly expressed upon exploration of novel environments. Furthermore, loss of Arc/Arg3.1 function impairs acquisition of spatial learning. Together, these findings suggest Arc/Arg3.1 to play a pivotal role in spatial coding, although the mechanism by which it is involved in spatial representation is elusive.
To study the involvement of Arc/Arg3.1 in these processes, we recorded hippocampal CA1 ensembles and local field potentials in four wildtype (WT) and three Arc/Arg3.1 knock-out (KO) mice using a 24-channel "Lantern" microdrive while they ran a circular maze motivated by sucrose pellets. The circular maze task was conducted in identically designed circular mazes placed in two different environments (different odor and visual cues, lighting and noise levels). Each mouse was recorded for four sessions in each condition, yielding 104 cells in WT mice and 101 cells in KO mice.
Consistent with previous behavioral studies, Arc KO animals expressed no difference in baseline behavior such as movement speed. We also found the sleep architecture of the Arc KO animals to be indistinguishable from that of the WT animals.
Analysis of place cell activity did not indicate robust changes in firing rates of putative pyramidal cells. However, place fields of KO mice appeared to have a lower degree of coverage of the arena (i.e., smaller place field size). Furthermore, KO mice had a specific attenuation in high frequency bands, particularly in beta2 (23-30Hz) and gamma (35-100 Hz) range. These results suggest that Arc/Arg3.1 is important for the constitution of spatial representations and types of fast temporal processing implied in spatial coding and memory formation.

Title: Hippocampal replay events in the context of a spatial working memory task

Authors: *H. TANILA[1,2], S. KU[2], F. KLOOSTERMAN[2,3,4], M. A. WILSON[2]
[1]A. I. Virtanen Inst., Univ. Eastern Finland, Kuopio, Finland; [2]Picower Inst. for Learning and Memory, MIT, Cambridge, MA; [3]NERF, Leuven, Belgium; [4]IMEC, Leuven, Belgium

Abstract: In exploration, during pauses characterized by sharp-wave-ripple events in hippocampal EEG, ensembles of place cells re-express firing sequences that correspond to recent spatial experience. Such ‘replays’ often start or end at the current location of the animal, but may also represent a remote location. Selective disruption of sharp-wave-ripples has been shown to impair spatial learning, but evidence is still lacking to link replay events directly to memory formation.
To this end, we recorded ensembles of 40 to 80 CA1 place cells while the rat was running in a complex symmetric maze (180 cm x 140 cm) with high walls following a start left - turn right (or vice versa) nonmatch rule. A correct path choice was rewarded with 4 minipellets, while a wrong choice led to a blind alley and finally to a reduced reward size after the rat had returned and taken the correct path. The choice accuracy varied greatly during the 10-30 recording sessions in each of 4 rats, which enabled us to compare the contents of replay events during correct vs. erroneous choices. We used neural decoding to analyze replayed trajectories in detail. Instances of replay of trajectories toward goal or start box were found while the rat stopped in the middle of the maze. We are currently analyzing the relation between replayed trajectories, animal's behavior, and task performance.

Title: Involvement of increase in Zn^{2+} signal in hippocampal CA1 pyramidal neurons in stress-mediated memory deficit.

Authors: *M. NAKAMURA[1], S. TAKADA[1], M. SUZUKI[2], N. OKU[2], A. TAKEDA[1]
[1]Dept. of Bioorganic Chemistry, Grad. Sch., [2]Dept. of Med. Biochem., Univ. of Shizuoka, Global COE, Shizuoka, Japan

Abstract: Glucocorticoid-glutamatergic interactions have been proposed as a potential model to explain stress-mediated impairment of cognition. However, it is unknown whether glucocorticoid-zincergic interactions are involved in this impairment. Zn^{2+} is co-released with glutamate from zincergic neurons. In the present study, involvement of synaptic Zn^{2+} in stress-induced attenuation of CA1 LTP was examined in hippocampal slices prepared from young rats after exposure to tail suspension stress for 30 s, which significantly increased serum corticosterone. Stress-induced attenuation of CA1 LTP was ameliorated by administration of clioquinol, a membrane permeable zinc chelator, to rats prior to exposure to stress, implying that the reduction of synaptic Zn^{2+} by clioquinol participates in this amelioration. To pursue the involvement of corticosterone-mediated Zn^{2+} signal in the attenuated CA1 LTP by stress, dynamics of synaptic Zn^{2+} was checked in hippocampal slices exposed to corticosterone. Corticosterone increased extracellular Zn^{2+} levels measured with ZnAF-2 dose-dependently, as well as the intracellular Ca^{2+} levels measured with calcium orange AM, suggesting that corticosterone excites zincergic neurons in the hippocampus and increases Zn^{2+} release from the neuron terminals. Intracellular Zn^{2+} levels measured with ZnAF-2DA were also increased dose-dependently, but not in the coexistence of CaEDTA, a membrane-impermeable zinc chelator, suggesting that intracellular Zn^{2+} levels is increased by the influx of extracellular Zn^{2+}. Furthermore, corticosterone-induced attenuation of CA1 LTP was abolished in the coexistence of CaEDTA. These results suggest that corticosterone-mediated increase in postsynaptic Zn^{2+} signal in the cytosolic compartment is involved in the attenuation of CA1 LTP after exposure to acute stress. We examined the idea that the transient increase in Zn^{2+} signal in the cytosolic compartment affect on memory. Local injection of $ZnCl_2$ into hippocampal CA1 region increased intracellular Zn^{2+} levels in CA1 region, followed by object recognition memory deficit. In the case of the cytosolic increase in endogenous Zn^{2+} in the CA1 induced by KCl (100 mM 1

[[Unsupported Character - Symbol Font ]]l), furthermore, object recognition memory was also transiently impaired, while ameliorated by co-injection of 1 mM CaEDTA to block the increase in cytosolic Zn^{2+}. The present study indicates that the transient increase in cytosolic Zn^{2+} in CA1 pyramidal neurons may be involved in acute stress-mediated impairments of CA1 LTP induction and object recognition memory.

Title: Effects of high and low microstimulation in the nucleus accumbens in associative learning

Authors: *C. MARTINEZ-RUBIO[1], S. R. PATEL[1], S. C. FRY[2], E. N. ESKANDAR[1]
[1]Neurosurg., Massachusetts Gen. Hosp., Boston, MA; [2]Dept. of Biol., Univ. of Massachusetts, Boston, MA

Abstract: The nucleus accumbens is a collection of neurons found in the ventral striatum. This structure is thought to play an important role in reward-oriented behaviors and may underlie neurological disorders such as major depression, obsessive compulsive disorder, and drug addiction. Recent findings suggest that the nucleus accumbens encodes reward expectation and thus predetermines, in part, the motivation to perform behavioral tasks. In this investigation, two non-human primates were trained to perform a simple visual-motor association task. During this task, the animal was required to learn, by trail and error, to associate four images with a specific saccade direction; in each block, two images are novel and two are familiar. High and low microstimulation was applied during three different epochs of the task (initial fixation, stimulus,

and feedback) to one of the novel images in each block. Learning performance and reaction times were evaluated during each of these stimulated epochs. Our preliminary results show an improvement in the learning rate using low frequency stimulation during the fixation epoch of the task. Moreover, low frequency stimulation seems to reduce reaction times during initial fixation and stimulus presentation. Interestingly, application of high frequency stimulation has only shown an effect during the stimulus presentation. These results increase our understanding of the role of the nucleus accumbens in associating learning and the possibilities of a potential new treatment of various disorders related to mood and motivation.

Title: Social presence modulates visuomotor learning in macaque monkeys

Authors: *M. DEMOLLIENS[1], F. ISBAINE[1], A. BROVELLI[2], D. BOUSSAOUD[1], P. HUGUET[3]
[1]Inst. Des Neurosciences Des Systèmes, UMR1106-INSERM & Aix-Marseille Universi, Marseille, France; [2]Inst. des Neurosciences de La Timone, UMR7289-CNRS & Aix-Marseille Université, Marseille, France, Marseille, France; [3]Lab. de Psychologie Cognitive-LPC, UMR7290-CNRS & Aix-Marseille Université, & Fédération de Recherche 3C, Marseille, France, Marseille, France

Abstract: Interest in the way the presence of conspecifics affects individual behavior has a long history in social psychology, with a myriad of experiments involving species as diverse as humans and cockroaches. This presence was generally found to facilitate performance on simple or well-learned tasks, and to deteriorate performance on difficult or poorly learned tasks (compared with performance in isolation context). These phenomena, known as social facilitation/inhibition (SFI) effects, received much attention, but their boundary conditions and neural correlates remain poorly understood. Here, we addressed these important issues in non-human primates. Two macaques learned to perform simple or difficult visuo-motor tasks involving arbitrary associations between abstract images and spatial targets (white squares) on a

touch screen. They initiated a trial by putting the hand on a lever (white rectangle) located near their chest. Then a visual cue appeared together with 2 (easy task) or 4 (difficult task) targets. Pressing the correct target led to a success feedback (green ring) followed by a drop of fruit juice, whereas incorrect responses led to error feedback (red ring) with no reward. Each animal acted as “actor” or “observer”, i.e., performed new tasks in isolation and in presence of the other animal, or observed the other animal performing such tasks. Whereas half the targets were located in the actor’s personal space, the other half were located in the observers’ personal space, so as to test whether entering the observers’ personal space can moderate SFI effects _ an important but neglected point in past research. Finally, single neurons were recorded from the dorsolateral prefrontal cortex (DLPF) of one of the two monkeys, so as to determine the neural correlates of these effects. The behavioral findings offer preliminary evidence that SFI effects depend on whether task performance does or does not imply for the actor to enter the observer’s personal space. More importantly, the neural findings provide first evidence that the presence of conspecifics modulates learning-related activity of a significant proportion of single DLPF cells, with cells whose firing rate was stronger when the actor monkey learned in presence of the observer, compared to isolation, and cells with the opposite pattern; a neural pattern revealing new facets of the so-called social brain in primates. Thus, our findings reveal that entering the observer’s personal space matters in SFI effects, which helps specify the boundary conditions for these effects, and also make a significant first step toward a better understanding of the neurophysiological bases of such effects in primates.

Title: Oxytocin-based neuromodulation of mammalian social behavior

Authors: *B. J. JONES, R. C. FROEMKE
Mol. Neurobio., New York University, Sch. of Med., New York, NY

Abstract: Social interactions are essential for normative development and lifelong physical and mental health. The neuromodulator oxytocin is believed to be important for some forms of social behavior, specifically parent-child bonding and maternal behavior. Here we investigate a

fundamental form of rodent social behavior that depends on both social cues and modification of neural substrates: pup retrieval.
To initiate pup retrieval behavior, mouse pups produce ultrasonic vocalizations (USVs) when separated from the nest. Dams and other experienced caregivers use these acoustic signals to locate and retrieve isolated pups. Importantly, virgin female mice can also learn a variety of maternal behaviors, including pup retrieval, and we hypothesize that oxytocin plays a major role in this form of learned social behavior (Pedersen et al., Science 1982). However, it is unclear how oxytocin impacts the activity of the cortex, leading to the robust increase in maternal behavior.
We confirmed that virgins can also learn to retrieve pups. Furthermore, learning is accelerated after either systemic or cortical application of oxytocin. Virgins were first tested for initial retrieval abilities. Virgins were then co-housed with a dam and her pups for up to three days, with some animals receiving oxytocin and other animals receiving saline. After 12 hours of co-housing, 16/31 (~50%) animals injected with oxytocin learned to retrieve pups, but only 6/24 (25%) control saline-injected virgins retrieved pups. Similarly, 7/9 animals receiving oxytocin infusion into left auditory cortex via cannula retrieved pups within 12 hours, but 0/4 cannulated virgins receiving saline infusion retrieved pups. Finally, infusing the GABA-A receptor agonist muscimol into left auditory cortex, to inactivate local circuitry, reduced or fully prevented pup retrieval in 6/9 experienced animals. Infusion into right auditory cortex did not seem to significantly affect retrieval. This demonstrates that left auditory cortex is required for USVs to engage pup retrieval. Furthermore, these data suggest that oxytocin-based neuromodulation, paired with acoustic stimuli, can modify auditory cortex to enable or improve learned social behavior.

Title: Memory and forgetting : Implication of sleep.

Authors: *R. PARMENTIER, L. PRAST, M. YOUSSEF, J. COMTE, P. A. LIBOUREL, P. H. LUPPI, P. SALIN, G. MALLERET

Abstract: Our memory is our ability to retain and use knowledge or acquired information. Understanding the mechanisms underlying memory functions is essential.
Moreover, it is generally accepted that sleep is a process that promotes these memory processes. Given the differences between slow
wave sleep (SWS) and paradoxical sleep (PS), these two sleep phases must surely have different roles. The 'sequential function of sleep hypothesis' (Giuditta et al., 1995) suggests that these roles are interdependent. A first processing would result in a reduction of "non-essential" memory traces during SWS, while PS would allow the consolidation of the remaining relevant information. In other words, we can say that SWS would promote forgetting while PS would facilitate the consolidation of information. We tested this hypothesis by coupling in the rat an electrophysiological approach to sophisticated behavioral tasks aimed to assess three distinct forms of memory in a radial maze (Malleret et al., 2010): 1) a working memory (WM) task with high level of proactive interference (HIWM) during which storage of variable information is required but forgetting of previous trials is preferable for the animal not to be overloaded with irrelevant information, 2) a working memory task with low level of interference (LIWM) during which such forgetting is not required, and 3) a reference memory (RM) task requiring the long-term consolidation of invariable information. Each day, post-learning sleep EEG/EMG oscillatory activity was recorded.
We observed a transient increase in the amount of PS (+40%) the day the animal has learned the RM rule. This day was determined by a performance above 50% of correct responses that is maintained the day after. In HIWM, no quantitative changes in SWS or PS were noted during the ten days of learning. However, a significant positive correlation is seen between performance on day n+1 and the amount of SWS (but not PS) shown by the animal the day before (day n). This result suggests that the more time spent in SWS, the better the animal deals with interferences. In contrast, in LIWM, no notable change exists in the amounts of SWS or PS or in the correlations between SWS or PS and WM performance.
In conclusion, our results suggest that PS is transitorily involved in the long-term storage of information whereas SWS would be required for proper treatment of memory interference and therefore forgetting of irrelevant information required for working memory.

Title: Excitotoxic lesions of striatum spare head direction cell function within the anterodorsal thalamus.

Authors: *S. S. WINTER, S. VALERIO, J. S. TAUBE
Psychology and Brain Sci., Dartmouth Col., Hanover, NH

Abstract: Maintaining spatial orientation is a complex process that involves the coordination of multiple brain regions involved in processing selective components of spatial information. For example, head direction (HD) cells activate dependent upon the heading orientation of an animal within their environment functioning like a compass. The classic HD circuit projects from dorsal tegmental nuclei → lateral mammillary nuclei → anterodorsal thalamus → postsubiculum and retrosplenial cortex → entorhinal cortex. Information is processed serially through this circuit with integration of self-movement and environmental cues in distinct regions. Interestingly, HD cells have been located in areas outside of the classic HD circuit (i.e., striatum and medial agranular cortex), but their functional relationship to the known circuitry remains unknown. The current study examined the effect of excitotoxic striatal lesions upon the function of HD cells within the anterodorsal thalamus. Lesions of the striatum spared anterodorsal thalamic HD cell firing characteristics (peak firing rate, directional firing range), and control of HD firing by both visual landmarks and self-movement cues. These results provide evidence that striatal HD cells do not provide significant influence over thalamic HD cells, and suggest that striatal HD cells are generated from output of the classic HD circuit, most likely via subicular efferents or through its connections with the interpeduncular nucleus/habenula system, which has reciprocal connections with the dorsal tegmental nuclei.

Title: The nucleus prepositus contributes to head direction cell stability in rats

Authors: *W. N. BUTLER, J. S. TAUBE
Dartmouth Col., Hanover, NH

Abstract: The rat limbic system contains a unique population of cells that convey information about the animal's head direction (HD) in the horizontal plane. Previous studies have shown the importance of the vestibular system in generating the HD signal, but the roles of different nuclei within the ascending vestibular pathway to the HD cell circuit are largely unknown. Previous studies of the HD circuit have also shown a continuum of instability in HD cells following different lesions. Lesions of the retrosplenial cortex (Clark et al., 2010) or postsubiculum (Goodridge & Taube, 1997) led to HD cells whose preferred firing directions (PFD) drifted gradually as the animal moved about the environment, while lesions associated with the vestibular system led to cells which only fired in extended bursts of activity (Stackman & Taube, 1997; Muir et al., 2009; Yoder & Taube, 2009). Vestibular information is projected to the HD cell circuit via the nucleus prepositus hypoglossi (NPH) and supragenual nucleus (SGN). While SGN lesions disrupt direction-specific firing in the anterodorsal thalamus (ADN) (Clark et al., 2012), it has also been hypothesized that the adjacent NPH also plays a critical role in generating the HD signal.

To test this hypothesis, we made small bilateral electrolytic lesions of the NPH and recorded cell activity in the ADN in rats, an area that contains a high percentage of HD cells. Cells were monitored as rats foraged for food pellets dropped randomly onto the floor of a 76 cm diameter cylinder that contained a single prominent visual cue. The properties of cells recorded in the ADN of lesioned rats (n=6) were compared to the firing properties of HD cells in non-lesioned controls. Lesioned rats did not display stable HD-related activity; rather, they either had cells whose PFD drifted significantly at different rates throughout the recording session (n=5), or had cells whose PFD was highly unstable and fired in bursts (n=1). The number of these cells found in each lesioned rat was comparable to the number of HD cells found in controls. These results stand in contrast to findings when the SGN is lesioned, which led to the complete loss of direction-specific firing without any cells being recognizable as 'drifty' HD cells. These findings provide evidence that the NPH plays an important role in integrating vestibular cues with other inputs in order to maintain a stable HD cell signal.

Title: Observational learning in mice can be prevented by medial prefrontal cortex stimulation and enhanced by nucleus accumbens stimulation

Authors: *A. GRUART, M. JURADO-PARRAS, J. CARPONCY, J. DELGADO-GARCÍA
Divi Neurocie, Pablo de Olavide Univ., 41013 Seville, Spain

Abstract: The neural structures involved in ongoing appetitive and/or observational learning behaviors remain largely unknown. Ongoing behaviors are the result of underlying neural and cognitive processes that determine the sequence of motor activities and the proper analysis of the successive results. It can be assumed that electrical stimulation of the brain structures putatively involved in those processes affect only behavioral sequences present at the precise moment of the stimulation. We decided to study the putative modification of ongoing behaviors, and of the acquisition of new cognitive abilities by the electrical stimulation of selected brain sites in alert behaving wild-type mice. Operant conditioning and observational learning were evoked and recorded in mice with the help of a modified Skinner box provided with an on-line video recording system. Animals were implanted with chronic EEG recording and/or stimulating electrodes in selected hippocampal, prefrontal, and/or accumbens nucleus sites. Animals were firstly trained for the acquisition of a fixed (1:1) ratio schedule and then switched to different experimental protocols. Naïve mice improved their acquisition of a simple operant conditioning task by observational learning; that is, observing the proper performance of a demonstrator during the instrumental conditioning task. Electrical stimulation of the observer's medial prefrontal cortex (mPFC) at a key moment of the demonstration - that is, when the demonstrator presses a lever in order to obtain a reward - cancels out the benefits of observation. In contrast, electrical stimulation of the observer's nucleus accumbens (NAc) enhances observational learning. Ongoing cognitive processes in the demonstrator could also be driven by the electrical stimulation of these two (mPFC and NAc) structures, preventing the proper execution of the ongoing instrumental task (mPFC) or stopping pellet intake (NAc). Long-term potentiation

(LTP) evoked in these two structures did not prevent the acquisition or retrieval process - namely, mPFC and/or NAc stimulation only prevented, or modified, the ongoing behavioral process. EEG recorded at both mPFC and NAc was modified during the acquisition process and the observational period. The dorsal hippocampus was not involved in any of these two behavioral processes. In addition, LTP evoked in the dorsal hippocampus did not prevent the acquisition process and/or its proper performance. Thus, both ongoing observational learning and performance of an instrumental task require of the active contribution of the mPFC and the NAc nucleus.

Title: Effects of insulin on CA1 pyramidal neurons in the trim vs. obese rat hippocampus

Authors: *E. UNDERWOOD[1,2], L. T. THOMPSON[2]
[1]Plano, TX; [2]Behavior and Brain Sci., Univ. of Texas at Dallas, Richardson, TX

Abstract: Insulin has been shown to affect not only glucose utilization but also synaptic transmission in the CA1 region of the hippocampus, a region critically involved in learning new tasks and in consolidation of declarative memories. Learning-dependent plasticity of CA1 post-burst AHPs and spike-frequency accommodation have been reported by our own lab and many others following task acquisition, in multiple tasks and multiple species. Preliminary work from our lab has shown that insulin increases intrinsic excitability of CA1 pyramidal neurons. Obese rat models have been shown to have decreased performance in tests of spatial learning and decreased measures in excitability. The current study assessed excitability effects across a range of physiological concentrations in average weight (trim) and obese rats, preliminary to learning and memory-related studies. Young adult male rats fed either a control diet or a high-fat high carbohydrate diet for 6 weeks were anesthetized, and 400 µm brain slices including ventral and dorsal CA1 or horizontal slices including only ventral CA1 were prepared for recording. Sharp electrodes filled with 3M KCl were used for intracellular recordings from submerged slices held at 30°C in oxygenated aCSF using standard protocols. Measures of excitability (including

mAHP, sAHP, and AHP peak amplitudes, AHP duration and area, and of spike-frequency accommodation), input resistance, and sag were assessed from neurons held at -67 ± 2 mV. Vehicle (aCSF) or various concentrations of insulin (0.0 - 50 µM) were then bath applied and these measures were again assessed. Insulin increased excitability of CA1 pyramidal neurons in a concentration-dependent manner. All AHP measures were reduced, along with decreased accommodation (increased spike firing to a sustained input). U-shaped dose-response curves typical of other nootropic drugs enhancing hippocampal excitability were observed. Comparisons of intrinsic excitability before and after insulin perfusion between neurons from trim and obese rats were consistent with impairments associated with glucose and insulin dysregulation. The results have implications both for future learning and memory studies and for diabetics and others managing blood glucose levels with insulin treatments.

Title: Expression of novelty in the hippocampus: Reductions in post-burst AHPs of CA1 pyramidal neurons after single novel experiences

Authors: *E. S. LOVITZ, J. P. ELLIS, E. D. VERA, A. S. FIRMAN, L. T. THOMPSON
Univ. of Texas at Dallas, Richardson, TX

Abstract: Novel experiences are a trigger for the initiation of learning, in which the brain distinguishes between something familiar and something new, whether a difference in environment, task, or cue. Novelty can activate multiple brain regions involved in reward and memory, but responses quickly diminish after reexposure. Dopamine (DA) release from the substantia nigra (SN) and ventral tegmental area (VTA) is triggered by novelty; Steinfels et al. (1982) reported enhanced firing rates by DA neurons in the SN and VTA (Horvitz et al. 1998) during presentations of novel unconditioned clicks or light stimuli. fMRI studies show BOLD signal changes in these same regions during novel cue learning tasks (Schott et al. 2004; Wittman et al. 2005; Bunzeck & Duzel 2006). fMRI and EEG studies show the hippocampus and parahippocampal areas, which receive DA inputs, are active during presentation of novel stimuli. In rats, LTP is enhanced after neonatal exposure to a novel environment (Tang & Zou 2002).

Jeewajee et al. (2008) found exposure to novel environments reduces theta frequency in the hippocampus, and exposure to an unexpected environment leads to a greater reduction in theta frequency than novelty alone. Our lab (Farmer et al., 2012) found reductions in ventral CA1 (vCA1) pyramidal neuron post-burst afterhyperpolarization (AHP) amplitudes following exposure to a novel inhibitory avoidance shuttle box, lasting up to 1 hr post exposure. The current study extends these findings, using two different novel experiences.
Male LE rats (2 mo) were handled daily for 5 min over 3 d to habituate them to handling, then exposed the next day once to a novel open field environment, or trained on a novel object detection task. Rats were sacrificed 1 hr post-exposure or post-training, and intracellular recordings were made from 400 µm slices containing vCA1. Sharp electrodes filled with 3M KCl were used for intracellular recordings from pyramidal neurons in submerged slices at 30°C using standard protocols. RMP, IR, sag, and multiple measures of excitability (AHP peak amplitude and duration, measures of mAHP and sAHP, and of accommodation) were assessed from neurons held at -67±3 mV.
We found reductions in AHPs after exposure to a novel open field similar to those reported after exposure to a novel IA shuttle box. These findings suggest novelty is encoded by vCA1 pyramidal neurons via AHP plasticity, and may initiate learning of more salient information.

Title: Hippocampal place cells and interneurons in tinnitus: Time course of behavioral and single-unit plasticity

Authors: *M. R. KAPOLOWICZ, S. B. TEMPLET, S. YAN, L. T. THOMPSON
Behavioral and Brain Sci., The Univ. of Texas at Dallas, Richardson, TX

Abstract: Møller (2004) and Eggermont & Roberts (2004) speculate that tinnitus-related plasticity occurring in the limbic system is due to the activation of the extralemniscal auditory pathway which is not typically active in healthy adults (Møller & Rollins, 2002). By way of the dorsal-medial thalamus, the non-classical ascending auditory pathway is afferent to the limbic

system, and it can trigger plasticity that contributes to the pathology of tinnitus. Goble *et al*. (2009) showed that place-fields of neurons in the CA1 region of the hippocampus destabilize within 15 min of high intensity noise exposure in an experimental tinnitus model, with plasticity continuing across at least the next 24 hr. The aim of the current study is to characterize both the nature and long-term time course underlying this place-field plasticity by comparing CA1 excitatory (complex-spike) pyramidal neuron activity and inhibitory (theta) interneuron activity with behavioral signs of tinnitus. Adult male Long-Evans rats were chronically implanted with individually drivable multi-tetrode bundles into dorsal CA1 and trained to search for 0.1 mL chocolate milk rewards at the ends of the arms of a radial maze for identification and assessment of interneuron activity and of place cell place-field stability. Rats were pre-tested for absence of tinnitus using a gap detection startle paradigm adapted from Turner *et al*. (2006). A day later, rats were randomly assigned as controls (placed in the sound apparatus without auditory stimulation) or for tinnitus induction (bilaterally exposed to a 16 kHz tone at 115 dB SPL for 1 hr). Immediately following this exposure, 10 min maze recording sessions were repeated multiple times daily for up to 1 mo. Single-unit activity and spatial location were monitored in each session using a Plexon Inst. MAP system to quantify neuronal activity and characterize place-fields on several dimensions. Rats were examined weekly for behavioral evidence of tinnitus using the gap detection startle paradigm. Single-unit activity and behavioral data from controls and noise-exposed rats were compared and assessed at time intervals throughout the post-exposure period. Behavioral evidence of tinnitus developed much more slowly than plasticity in place-fields within the hippocampus. The relationship between place cell plasticity and interneuron plasticity was also compared across these intervals. The early onset of hippocampal plasticity prior to evidence of behavioral plasticity (i.e. ringing in the ears associated with tinnitus) then serves as a basis for testing the effectiveness of therapies designed to reduce or eliminate both forms of plasticity.

Title: BLA modulation of CA1 place field plasticity when an auditory CS is specifically paired with place cell firing

Authors: *E. J. DONZIS, L. T. THOMPSON
Univ. of Texas at Dallas, Richardson, TX

Abstract: The basolateral complex of the amygdala (BLA) is involved in emotional learning and spatial memory and modulates plasticity in multiple brain regions, including the hippocampus during spatial learning. Pyramidal cells in the CA1 region of the hippocampus fire preferentially when a rat is in one specific location of an environment. These cells are known as place cells and the area in which they preferentially fire is the place field. Changes seen in a cell's place field indicate a change in that cell's activity. Changes in the physical components of an environment typically result in place field plasticity. Nonphysical changes, such as fear conditioning a rat in an environment, also result in generalized place field plasticity. It is unknown what happens to place fields when a fear conditioned stimulus (CS) is associated with only one particular location in an environment, nor the physiological mechanisms for fear-conditioning-related place field plasticity. Hebbian learning suggests that CS presentation in a specific place will result in plasticity of cells firing during CS presentation (i.e. within their place field) and a lack of changes in cells not firing (i.e. outside their place field). This plasticity is likely due to BLA modulation of hippocampal activity.
Rats were implanted with 4 individually drivable tetrodes in the CA1 of the dorsal hippocampus and a guide cannula into the BLA. Rats were trained to explore all 8 arms of a radial-arm maze until stable unit activity was established using a Plexon MAP system. Rats were placed in a completely separate environment and presented a tone CS (70 dB, 5 kHz, 5 sec) paired 3 times (ITI 4 min ± 30 sec) with a footshock (0.5 mA, 1 sec). 24 h later, the rats were returned to the radial-arm maze and the CS was presented. Immediately after CS presentation, lidocaine or saline was infused into the BLA. Unit activity was recorded at intervals 0.5 to 24 h post-CS presentation and place field maps constructed for each neuron for each recording session. Place field firing plasticity was compared before and after CS presentation between lidocaine and saline infused rats. Freezing responses to CS presentation was also compared to rats that received pseudoconditioning (3 tone CS presentation and 3 footshocks unpaired).
Auditory fear conditioning resulted in increased freezing to the CS compared to pseudoconditioning. Place field stability increased when the CS was presented out-of-field (i.e. when a place cell was not firing) whereas place fields were disrupted when the CS was presented in-field (when the place cell was firing). Infusion of lidocaine into the BLA immediately post CS presentation in-field attenuated this place field plasticity.

Title: Firing rate dynamics underlying stress-induced impaired spatial encoding in the hippocampal network

Authors: *A. TOMAR[1], D. POLYGALOV[2], S. CHATTARJI[1], T. J. MCHUGH[2]
[1]Natl. Ctr. For Biol. Sci., Bangalore, India; [2]Lab. for Circuit and Behavioral Physiol., RIKEN Brain Sci. Inst., Wako City, Saitama, Japan

Abstract: Repeated and uncontrollable stress has debilitating effects on hippocamapal structure and function. Rodent models of stress exhibit deficits in spatial learning tasks, while at the cellular level, dendritic atrophy and impaired synaptic plasticity is observed across hippocampus in these animals. Surprisingly, the neuronal ensemble responses, that can provide an insight into stress-induced spatial memory deficits, either during stress or afterwards, remains poorly studied. Therefore we monitored hippocampal ensemble activity (dorsal CA1) during repeated stressful experiences (Immobilization: 2h/d for 10d) and also when mice explored different linear tracks or rested. Here we show that the first exposure of immobilization stress (D1) initially caused muted neuronal firing (first 30 min). This stress-induced deficit in neuronal firing recovered at later stage of stress (last 30 min). However, the effects of stress grew stronger with repeated applications, as on day 6 the initial firing was higher than that of D1. In fact, by the last day of stress (D10), neuronal firing rate remained abnormally high throughout the 2 h of immobilization episode. Consequently, one day after termination of chronic stress (D11), stress group showed enhanced neuronal excitability during rest/sleep state . To investigate the impact of chronic stress on spatial representations, we recorded place cell activity while mice explored familiar and novel linear tracks. On day 6, stressed animals showed impaired spatial representations during exploration of a familiar track. However, novel track representations were found intact as no difference was observed in either place field size or firing rates between control and stress group. Later, one day after termination of chronic stress (D11), stress group exhibited impaired spatial representations, as these animals failed to show novelty-induced enhancement of firing rate. Together, these data suggest that repeated stress interferes with neuronal excitability of CA1 neuron and induces firing rate rigidity as stressed animals failed to change their firing rates across different context and reveals differential effects of the chronic versus transient impact of stress.

Title: The altered spiking pattern of CA1 pyramidal cells of mice with CA1-selective deletion of Cav2.1 P/Q-type Ca^{2+} channel.

Authors: *D. JUNG[1,2], H. SHIN[1], J. CHO[1,2]
[1]Seongbok-Gu, Korea Institude of Sci. and Technology(Kist), Seoul, Korea, Republic of; [2]Univ. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: Voltage-gated Calcium channels (VGCC) mediate Ca^{2+} flux in response to neural signals. Various subtypes of these channels are involved in Ca^{2+}-dependent processes including neurotransmitter release and synaptic plasticity through diverse neuronal mechanisms. Although Cav2.1 P/Q type calcium channel, a subtype of the VGCCs, is highly expressed in the hippocampus, its role for spatial memory has rarely been studied compared to other families of VGCCs. Hippocampal pyramidal neurons are known for location-specific discharges, showing 2 distinct spiking patterns: single spike and complex spiking burst. The recent study showed the role of temporal spiking characteristics of CA1 place cells in relation with spatial learning/memory. However, factors affecting the spiking properties of the pyramidal cell and learning/memory behavior are still unknown. Therefore, using mice with CA1 selective deletion of Cav2.1 P/Q type Ca^{2+} channel, we conducted single unit recordings of the pyramidal cells to elucidate the role of P/Q type Ca^{2+} channel on the structure of CA1 pyramidal spiking. Our study showed the conditional knock-out mice had tendency of reduced burst frequency and increased single spike frequency, resulting in decrease of the burst ratio while the overall spike number was not different. Moreover, temporal properties of bursting were also altered in terms of prolonged intra-burst interval and temporal burst length. These results suggest that P/Q type calcium channels could be involved in shaping the spiking pattern of CA1 place cells.

Title: Creation of hippocampal place fields via single-cell manipulation of excitability during spatial exploration

Authors: *D. LEE, B.-J. LIN, A. K. LEE
Howard Hughes Med. Institute, Janelia Farm Res. Campus, ASHBURN, VA

Abstract: The mechanism underlying hippocampal place cell firing is not known. For CA1 pyramidal neurons, the spatiotemporal summation of converging inputs from other spatially-tuned neurons in CA3 and the entorhinal cortex is considered to play a pivotal role in determining the spatial code, i.e., whether each cell is a place or silent cell in a given environment. Employing the whole-cell recording technique in freely moving rats, we show that manipulating a single CA1 pyramidal neuron's excitability without affecting its presynaptic activity reversibly converts the cell between place and silent modes during spatial exploration. A spatially-uniform depolarization of the somatic membrane potential (V_m) of a silent cell caused not only place field spiking but also an underlying spatially-tuned subthreshold response to appear. Conversely, a spatially-uniform hyperpolarization of a place cell prevented both the spatially-tuned subthreshold response and spiking. Graded manipulation of V_m by applying multiple levels of current injection revealed that the subthreshold response suddenly occurs above a cell-specific threshold. When no current was injected into silent cells, no difference in mean V_m, input resistance, or Vm fluctuations was found between the location of the eventual place field and the region outside of this field, implying that spatially-tuned synaptic inputs do not reach the soma at the resting V_m level. These results suggest that gating of inputs into the soma by cellular excitability may be a decisive factor for the spatial code.

Title: Electrophysiological characterization of spatial memory cells in the anteromedial thalamic nuclei

Authors: *E. D. TRAN[1,2,3], J. PASSECKER[2], S. O'MARA[2]
[1]Thao Da Tran, Richmond, TX; [2]Inst. of Neurosci., Trinity Col., Dublin, Ireland; [3]Ctr. for Learning and Memory, Univ. of Texas at Austin, Austin, TX

Abstract: The Papez circuit appears to play a crucial role in the formation of episodic memory. In particular, the interconnections between the hippocampus and the anterior thalamus seem to be vital for an animal's mnemonic ability to orientate itself to and navigate through its environment. This is further supported by electrophysiological studies in freely moving rats, which have discovered neurons that encode for location (place cells) in the hippocampus and directional heading (head direction cells) in the anterodorsal and anteroventral nuclei of the thalamus. Due to the relative inaccessibility of the anteromedial nucleus of the thalamus, its electrophysiological properties are not well-characterised, and its role in spatial processing and cognition still remains elusive. In this study, we were able to successfully record from a population of head direction (20%) and theta rhythmic neurons (15%) in the anteromedial thalamic nucleus, suggesting that this structure plays an important role in the temporal-diencephalic-cortical pathways that regulate spatial processing.

Title: Hippocampal dopamine deficiency underlies spatial learning deficits in Neurofibromatosis-1 mutant mice

Authors: *K. A. DIGGS-ANDREWS, K. TOKUDA, Y. IZUMI, C. F. ZORUMSKI, D. F. WOZNIAK, D. H. GUTMANN
Washington Univ. In St. Louis, Saint Louis, MO

Abstract: Children with the cancer predisposition syndrome Neurofibromatosis type 1 (NF1) are prone to learning and behavioral abnormalities, including problems with spatial learning and attention. Studies in *Nf1* genetically-engineered mice (*Nf1* CKO) have uncovered defects in neuronal morphology and function along with cognitive defects, yet the molecular mechanism underlying these deficits remains unclear. Using primary neuronal culture, electrophysiology, and behavioral testing, we demonstrate that a primary defect influencing hippocampal neuron function and spatial learning/memory in CKO mice is impaired dopamine signaling. Direct measurements of hippocampal dopamine levels (20%) and its downstream effector DARPP32 (60%) show that dopamine signaling is significantly reduced in CKO mice relative to controls. In cultured neurons, *Nf1* loss results in shorter neuronal processes and growth cones. These hippocampal neuron defects are completely rescued by either dopamine (100uM) or dopamine D1 receptor agonist (SKF38393, 1 uM) treatment *in vitro*. Functionally, long-term potentiation (LTP) of CKO slices is diminished (128.8+ 7.6%, n=8) in response to high frequency stimulation (HFS) (control, 165.2 + 6.8%, n=8). This response is completely restored by a dopamine D1 receptor agonist (SKF38393; 158.5+7.7%, n=8, $p<0.01$ vs. untreated). Further, dopamine (L-DOPA) treatment ameliorates the spatial learning abnormalities in *Nf1* CKO mice *in vivo*. Specifically, untreated CKO mice show no spatial bias in the Morris Water Maze. Following L-DOPA treatment, CKO mice exhibit significant spatial bias comparable to controls ($p<0.002$ for target vs all others). Together, these results firmly establish defective dopaminergic function as a primary abnormality underlying both spatial learning/memory and hippocampal function in *Nf1* mutant mice.

Title: Identification and characterization of parvalbumin-expressing interneurons in the medial entorhinal cortex of behaving mice

Authors: *C. BUETFERING, A. KEVIN, W. KELSCH, H. MONYER
Dept. of Clin. Neurobio., Dept. of Clin. Neurobio. of Univ. Hosp. and DKFZ, Heidelberg, Germany

Abstract: A comprehensive understanding of how the medial entorhinal cortex (MEC) processes spatial information will require a cell-type specific dissection of its local circuitry. A major cell type carrying spatial information in the MEC are grid cells that fire only at the vertices of a grid of equilateral triangles. Inhibitory interneurons in the MEC may control grid cell activity via local inhibitory feedback. However, the interactions between grid cells and interneurons are largely unknown. Here we studied the function of parvalbumin-expressing (PV) interneurons by combining tetrode recordings and cell-type specific photostimulation. Cre-dependent viral expression of Channelrhodopsin-2 in the MEC of parvalbuminCre mice allowed regionally selective photostimulation of PV interneurons in behaving mice. Brief pulses of light (10 ms, 6 Hz, 473 nm) were used to unambiguously identify PV interneurons. PV interneurons and simultaneously recorded grid cells represented two distinct neuronal populations. In comparison to grid cells, PV interneurons had higher mean firing rates, lower grid scores and their firing was less spatially selective. The firing rate of both cell types was modulated by theta oscillations, with the peak firing of most grid cells occurring at the descending phase and preceding the peak firing of PV interneurons. Spike-time crosscorrelation analysis revealed the presence of putative monosynaptic excitatory connections between grid cells and PV interneurons. Conversely, photoactivation of PV interneurons led to a strong inhibition of grid cell activity. These results are consistent with the existence of an inhibitory feedback circuit between PV interneurons and grid cells. We are currently examining the functional involvement of this connectivity for the spatial firing of grid cells.

Title: Involvement of neurotransmitters in the action of apelin.13 on passive avoidance learning

Authors: *G. TELEGDY[1], A. ADAMIK[2], M. JASZBERENYI[2]
[2]Pathopysiology, [1]Univ. Med. Sch., Szeged 6701, Hungary

Abstract: Involvement of neurotransmitter in the action of apelin-13 on passive avoidance learning in rats.
Gyula Telegdy [a,b], Agnes Adamik[a], Miklós Jászberényi[a].
Department of Pathophysiology[a], Neuroscience Research Group of the Hungarian Academy of Sciences[b], University of Szeged, Szeged Hungary,
The action of apelin-13 on passive avoidance learning has been tested in rats. Apelin-13 facilitated the consolidation of passive avoidance learning in a dose-dependent manner, however was ineffective on retrieval processes.
In order to asses the possible involvement of transmitters in this action, the animals were pretreated with receptor blockers in doses with itself did not influence the behavioral paradigm. The following receptor blockers were used: a nonselective α-adrenergic receptor antagonist, phenoxybenzamine, a β-adrenergic receptor antagonist, propranolol, a nonselective 5-HT2 serotonergic receptor antagonist, cyproheptadine, a nonselective muscarinic acetylcholine receptor antagonist, atropine, a D2, D3, D4 dopamine receptor antagonist, haloperidol, a γ-aminobutyric acid subunit **A** (GABA-A) receptor antagonist, bicuculline, and a nonselective opioid receptor antagonist, naloxone.
Phenoxybenzamine, , cyproheptadine, atropine, haloperidol, bicuculline prevented the action of apelin 13 on the consolidateion of passive avouidance learning. Propranolon and naloxone were ineffective.
The data suggest that apeling-13 elicits its action on passive avoidance consolidation via α-adrenergic, 5-HT2 serotonergic, cholinergic, dopaminergic and GABA-A-ergic mediation.

Title: Role of ITSN-1 in learning and memory

Authors: *N. MALAKOOTI[1], H. A. COLEMAN[2], X. M. LIM[2], A. CORLETT[3], D. I. FINKELSTEIN[4], H. C. PARKINGTON[2], M. A. PRITCHARD[3]
[1]Dept. of Biochem. and Mol. Biol., [2]Physiol., [3]Biochem. and Mol. Biol., Monash Univ., Clayton, Australia; [4]Mental Hlth. Res. Inst., Parkville, Australia

Abstract: Intersectin1 (ITSN1) is present on Chromosome 21 and over-expressed in Down syndrome (DS). All DS individuals exhibit learning and memory impairment. ITSN1 functions as a scaffolding protein involved in endocytosis and exocytosis and hence contributes to pre- and post-synaptic plasticity. In this study, we examined the role of ITSN1 in pre-synaptic plasticity using paired pulse facilitation (PPF) and post-synaptic plasticity via long term potentiation (LTP). A Morris water maze test was also used to examine spatial learning and long-term memory. Itsn1 long isoform-specific null (Itsn1-LKO) and wild type (WT) male mice were used for both studies.
In hippocampal brain slices (300 µm) a recording electrode was placed in CA1 stratum radiatum and a stimulating electrode in the Schaffer collaterals. PPF was recorded at 500, 160, 70 and 25 ms interpulse intervals. For LTP, field excitatory synaptic potentials (fEPSPs) were evoked by stimulation every 20 s for 20 minutes followed by 4 bursts of 100 Hz for 1 s, at 20 s intervals. Then the routine of a single stimulation every 20 s was resumed for 3 hours.
PPF was significantly enhanced from 1.65± 0.06 (n= 12) to 1.99± 0.12 (n=20) fold at 70 ms (p=0.01) in LKO mice. LTP was also significantly enhanced from 1.8 ± 0.1 (n=8) fold in WT slices to 2.9 ± 0.3 fold (n=13) (p=0.001) in Itsn1-LKO animals. While LTP had completely declined to basal level by 2 h in WT slices, 1.6 ± 0.2 fold remained at 2 h in KO slices. This result is interpreted in terms of slowing of endocytosis-driven removal of post-synaptic receptors in the dendritic spines.
For the water maze test, 5-6 month old mice were used (n=11 per genotype cohort). In a 150 cm diameter circular pool, an escape platform was placed in a fixed position (NW quadrant, 25cm from the wall). The pool was filled with tepid water (23 degrees C), and non-toxic paint was added to the water to create an opaque appearance. Over the 6 days of place discrimination training to learn the position of the submerged platform, Itsn1-LKO mice (mean of 84.6 seconds) showed slower escape latencies than WT (mean of 37.6 seconds) with a P value of 0.0058. These data indicate that ITSN1 is involved in synaptic plasticity and spatial learning and long term memory. Therefore when over-expressed, ITSN1 may contribute to the learning and memory deficits characteristic of DS.

Neurosci. Inst., Univ. of Cambridge, Cambridge, United Kingdom; [5]Neurosci. Inst., CNR, Pisa, Italy; [6]Dept. of Psychology, Univ. of Florence, Florence, Italy

Abstract: Perineuronal nets (PNNs) are extracellular matrix structures that form around the synapses on the cell soma and proximal dendrites of neurons. Previously, it was shown that genetic or pharmacological removal of PNNs reactivates plasticity in the adult CNS. Therefore, we hypothesised that manipulation of PNNs may also enhance cognitive processes requiring synaptic plasticity, such as declarative/explicit learning and memory. Expression of the link protein Crtl1/Hapln1 in neurons has recently been identified as the key event triggering the formation of PNNs. Here we tested adult mice lacking the Crtl1 gene in the CNS on an object recognition paradigm and showed that the attenuation of PNNs dramatically enhances long-term object recognition memory. Virtually identical prolongation of memory followed digestion of PNNs in the perirhinal cortex with chondroitinase ABC. Moreover, we performed extracellular field recordings in the perirhinal cortex of Crtl1 knock out mice and found that depleted PNNs facilitated Long Term Depression, a synaptic plasticity mechanism thought to underlie the encoding of this type of memory. Our results suggest that removal of PNNs may be used to enhance cognition, and reveal a previously unknown mechanism regulating synaptic plasticity processes important for learning and memory.

Title: Spatial representation in the macaque entorhinal cortex

Authors: *N. J. KILLIAN[1,2], M. J. JUTRAS[2,3], E. BUFFALO[2,4]
[1]Wallace H. Coulter Dept. of Biomed. Engin., Georgia Tech. and Emory Univ., ATLANTA, GA; [2]Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [3]Emory Univ., Atlanta, GA; [4]Neurol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Place-modulated activity of neurons in the hippocampal formation presents a means to organize contextual information in the service of memory formation and recall (Moser et al., 2008). In particular, grid cells and border cells have been observed in the entorhinal cortex (EC) of rats and bats (Hafting et al., 2005, Yartsev et al., 2011), but have yet to be described in single units in primates. Here, we examined spatial representations in the EC of head-fixed monkeys performing a free-viewing visual memory task (Jutras and Buffalo, 2010). Individual neurons were identified in the primate EC that emitted action potentials when the monkey fixated multiple discrete locations in the visual field across the presentation of up to hundreds of novel images. These firing fields possessed spatial periodicity that was reflected in a hexagonal pattern in the spatial autocorrelation. Analyses of 60° symmetry in the autocorrelation revealed a significant proportion of EC neurons could be classified as grid cells, based on accepted methods used to analyze rodent grid cells (12%, 23/193, $p<0.05$; Sargolini et al., 2006). A separate significant population of neurons in the EC preferentially fired when part of the stimulus bounds were viewed, analogous to rat border cells (9%, 18/193, $p<0.05$; Solstad et al., 2008). One prominent model of the generation of the grid structure requires theta-band modulation of grid cell spiking. In support of this model, it was recently demonstrated that, in rodents, disruption of theta oscillations disrupts grid cell firing patterns (Brandon et al., 2011; Koenig et al., 2011). However, the necessity of this relationship was contested by Yartsev et al., 2011, who reported that grid cells in bats do not require theta oscillations, and that theta-band activity in bats occurs in discrete bouts in contrast to the continuous theta that is observed in rats. In the present study, 48% of EC neurons that passed the threshold to be considered grid cells (11/23) demonstrated

theta-band (3-12 Hz) oscillatory activity in the autocorrelogram (theta index > 5) with preferred spiking at the trough of the theta-band in the simultaneously recorded LFP. This modulation occurred in the presence of intermittent theta oscillations (bouts from 3-12 Hz with a median duration of 0.96 sec and a median inter-bout interval of 0.87 sec). Taken together, these data suggest that EC neurons in the primate display spatial representations that are in many ways analogous to grid cells and border cells that have been described in the rat. These spatial representations may provide a spatial and temporal framework to anchor the encoding of stimulus content in a complex visual scene.

Title: Loss of Zn2+ signal in the dentate gyrus affects object recognition memory without changing Ca2+ signal

Authors: *H. FUJII[1], S. TAKADA[1], M. NAKAMURA[1], N. OKU[2], A. TAKEDA[1]
[1]Dept. of Bioorgnic Chemistry, Grad. Sch. of Phamaceutical Sci., [2]Dept. of Med. Biochemistry, Grad. Sch. of Phamaceutical Sci., Univ. of Shizuoka, Global COE, Shizuoka, Japan

Abstract: The hippocampus plays an important role in learning, memory and recognition of novelty. The hippocampus is required for memory storage for a limited period of time after learning. The physiological role of histochemically reactive (chelatable) zinc in the hippocampus, which serves as a signal factor (Zn^{2+} signal), at glutamatergic (zincergic) synapses is poorly understood. The role of Zn^{2+} signal in learning and memory can be evaluated by the transient loss of Zn^{2+} signal by zinc chelators. In this case, it is required that the chelator does not interfere with the tightly bound zinc pool, such as zinc fingers and numerous catalytic enzymes, which are essential for cellular functions. Clioquinol (5-chloro-7-iodo-8-hydroxyquinoline; CQ) forms lipophilic chelates with cations such as zinc and copper and is a candidate for by the transient loss of synaptic Zn^{2+} signal. Clioquinol (5-chloro-7-iodo-8-hydroxyquinoline; CQ) has a relatively weak affinity for zinc (K_d, approximately 1×10^{-7} M). N,N,N',N'-Tetrakis-(2-pyridylmethyl) ethylendediamine (TPEN: $K_d = 2.6 \times 10^{-16}$ M) also forms a lipophilic chelate with zinc and has a higher affinity for zinc. Both chelators have the potential as scientific tools to

evaluate the role of synaptic Zn^{2+} signal in normal animals. Here we analyzed the effects of the transient loss of Zn^{2+} signal in the dentate gyrus by zinc chelators to evaluate the role of Zn^{2+} signal in the dentate gyrus in object recognition memory. The induction of dentate gyrus long-term potentiation (LTP) under conscious condition, which were maintained more than for 6 days, were observed as an index of memory acquisition. The transient loss of Zn^{2+} signal in the dentate gyrus was induced by intraperitoneal injection of zinc chelators or local injection of zinc chelators into the dentate gyrus. The transient loss of Zn^{2+} signal in the dentate gyrus, which was determined by ZnAF-2 and ZnAF-2DA, a membrane-impermeable and membrane-permeable indicator, respectively, was induced 6 h after both injections At this time, the induction of dentate gyrus LTP and object recognition memory were affected. The loss of Zn^{2+} signal did not significantly affect intracellular Ca^{2+} signal determined by calcium orange AM in the dentate gyrus. When Zn^{2+} signal in the dentate gyrus was returned to the control level, dentate gyrus LTP and object recognition memory were observed normally. The present study demonstrates that synaptic Zn^{2+} signal in the dentate gyrus may be required for object recognition memory.

Title: Environmental enrichment mitigates cognitive deficits in weanling rats on a ketogenic diet

Authors: *J. P. HARNEY[1], J. SCICHILONE[2], D. BUTLER[2]
[2]Biol., [1]Univ. Hartford, WEST HARTFORD, CT

Abstract:
For decades the ketogenic diet (KD) has been an acceptable and moderately effective treatment of intractable epilepsy in children. Recent studies suggest that the KD, which commonly consists of a high fat, low carbohydrate and protein diet, has adverse effects on cognition in weanling rats. Rats reared in an enriched environment (EE) exhibit improved spatial learning, memory, and increased neurogenesis. Thus, the focus of the present study was to determine if weanling rats administered a KD experience altered learning, memory, anxiety or depression compared to rodent chow controls and if so would exposure to an EE reverse the effects of the KD. Weanling

rats were randomly assigned to either a standard rodent chow (RC) diet or a KD ad libitum, and housed in an EE or caged alone (ic) for 8 weeks. Weekly weights showed a steady increase in body mass for all groups with the RCic gaining the most weight. Blood ketones in rats fed a KD were significantly higher ($P<0.05$) in those raised in an EE (KDee) compared to those raised in isolation (KDic). Rats raised in an EE showed significantly improved learning ($P<0.05$) at both 4 and 8 weeks compared to those raised in isolation, however environment did not significantly impact memory retention. KD rats did show diminished memory at 8 weeks, but not at 4 weeks, compared to RC-fed controls. At 4, but not 8, weeks rats raised in an EE had less ($P<0.01$) anxiety than rats raised in isolation regardless of diet. Additionally, at 4 weeks RC fed rats were less anxious ($P<0.05$) than KD-fed rats. Interestingly, rats raised in isolation or fed KD were more mobile (thus less depressed; $P<0.05$) than EE or RC rats in the modified forced swim test. Hippocampal weights and BDNF levels were elevated in rats raised in an EE compared to those raised in isolation. In the present study we conclude that EE is a suitable means of retaining learning ability in weanling rats administered a KD. These findings suggest that environment should be an additional consideration for children receiving dietary therapies.

Abstract: Dementia and type 2 diabetes mellitus (T2DM) are common disorders that are increasing in prevalence, have a major impact on public health in the United States, and may have common causal pathways. Insulin resistance, a hallmark of T2DM, has been proposed as a risk factor for development of dementia as well as milder forms of cognitive impairment in aging humans. Rhesus monkeys develop metabolic disturbances with age, making them an ideal model species for studying T2DM. Affected macaques, primarily those with increased adiposity and older than age 10, demonstrate a syndrome characterized in part by impaired glucose tolerance and decreased insulin sensitivity. In the present study, we examined the relationship between metabolic disturbances and cognitive performance, as measured with a novel object recognition (NOR) test, in rhesus monkeys. Gross morphological measures, body composition (via DEXA-Scan) and response to intravenous glucose tolerance tests (IVGTTs) were determined in fifteen aged (mean=18-years old, SD=3.1) non-diabetic female rhesus monkeys. Monkeys then were tested in a NOR procedure with escalating phases of difficulty (Easy: 24 h access to identical objects, test with a single novel object; Moderate: 24 h access to different objects, test with a single novel object; Difficult: 10 min access to different objects, test with single novel object). Our results showed that successful performance on the NOR task positively correlated ($R^2=0.55$ to 0.79, $p<0.05$) with measures of insulin sensitivity during the IVGTT (glucose k rate/mean insulin levels). In addition, successful performance on the NOR task negatively correlated with mean insulin levels, as well as caliper measures of abdominal fat. These results suggest that performance on the NOR task was impaired in monkeys that were more insulin resistant and had higher abdominal fat levels when compared with healthy animals. In general, these findings suggest that a pre-diabetic condition is associated with impairments in cognition, which in turn might predispose individuals with T2DM to exacerbated cognitive decline.

Title: Sex-dependent differences in the response to cranial irradiation of the young mouse brain

Authors: *K. E. ROUGHTON[1], M. KALM[1], K. BLOMGREN[1,2]
[1]Univ. of Gothenburg, Gothenburg, Sweden; [2]Karolinska institutet, Stockholm, Sweden

Abstract: Radiation therapy in the treatment of pediatric brain tumors may lead to difficulties in cognitive functions later in life. These so called late effects may be influenced by age, treatment and gender. For example, young girls suffer more severe late effects compared to young boys. Unfortunately, most studies in this field of research have been performed using male rodents, and possible gender differences have not been considered. Therefore, we wanted to investigate possible short or long-term sex differences in response to cranial irradiation (IR) in mice. To do so, male and female mice were irradiated with a single dose of 8 Gray to the whole brain on postnatal day 14. We observed pronounced cell death in the brains of irradiated animals, as judged by caspase-3 activity 6 h after IR. IR also increased the levels of the chemokines MIP-1 alpha and CCL2 (MCP-1), indicating an acute IR-induced inflammation in the brain. No sex differences in these acute responses were however observed. Basal neurogenesis in non-irradiated mice was higher in females but this was not apparent until the animals were adult. Proliferation in the subgranular zone of the dentate gyrus in the hippocampus, as judged by the number of phospho-histone H3-positive cells, was reduced by half already 6 h after IR, same in males and females. This resulted in hampered growth of the granule cell layer (GCL), reduced BrdU incorporation and severely reduced neurogenesis (doublecortin-positive cells) in adulthood (4 months after IR), and this reduction was more pronounced in females. Irradiated mice displayed reduced brain weight, more pronounced in females (4.4% in males, 10.4% in females). To study behavioral effects after cranial IR, we used the open field test and the elevated plus maze 2 months after IR. The open field test showed that irradiated mice spent less time in the center of the arena, more pronounced in females (29% less in IR males, 54% less in IR females), possibly indicating increased anxiety. This was confirmed in the elevated plus maze, where females subjected to IR made shorter visits to the open arms, a difference that was not observed in males after IR. In an IntelliCage test, place learning was impaired by IR in females but not

males. Taken together, our results demonstrate that the young female mouse brain is more susceptible to ionizing radiation.

Title: Outside the olfactory bulb? An investigation into the role of the piriform cortex in early odor preference learning in rats.

Authors: *G. MORRISON[1,2], C. FONTAINE[2], C. HARLEY[2], Q. YUAN[2]
[1]St. John's, NL, Canada; [2]Mem. Univ. of Newfoundland, St. John's, NL, Canada

Abstract: Early odor preference learning provides us with a simple model to study cellular and synaptic processes that underlie learning and memory. In this model, we use associative learning and pair an aversive odor (peppermint) with tactile stimulation to train rat pups to form a preference for peppermint. Memory encoding processes in the olfactory bulb (OB) are well-documented during early odor preference learning, however the role of the olfactory cortex remains elusive. One major projection from the OB, the lateral olfactory tract (LOT), occurs in the dendrites of the pyramidal cells in layer Ia of the piriform cortex (PC). In this work, we investigate the role of the PC in early odor preference memory.
To gain insight into the role of the PC in early odor preference learning, we infused lidocaine (LIDO) into the anterior PC (aPC) at varying times during training or testing phases. LIDO transiently silences neurons, which was verified using pCREB immunohistochemistry (IHC). LIDO infusion into the aPC 10 minutes prior to training produced a reduced preference for peppermint bedding compared to saline-infused counterparts. In addition, LIDO infusion into the aPC 10 minutes prior to testing produced a reduced preference for peppermint bedding compared to saline-infused rats. These results suggest the aPC may play a role in both the encoding and retrieval of early odor memories. To expand on this, we used unilateral nostril occlusion and examined pCREB staining in pyramidal cells of the PC 10 minutes following either odor only or odor plus stroking. Preliminary results showed more pCREB staining in the spared hemispheres compared to occluded hemispheres, and more staining in the odor plus stroking animals compared to odor only.

To explore the cellular mechanisms underlying memory processes at the LOT-pyramidal cell synapse in the aPC we conducted *in vitro* electrophysiology recordings of field EPSP in layer Ia of the aPC with LOT stimulation. We induced long-term potentiation (LTP) following 1 theta burst stimulation (TBS), 4 TBS, and 8 TBS protocols. We studied the input/output relationship before and following LTP induction and used the initial slope of field EPSP to measure the AMPA components of EPSP. The ratio of the change in the presynaptic volley to the AMPA slope was measured and was greater post-LTP versus pre-LTP, suggesting a postsynaptic expression mechanism involved in LOT-PC LTP. Finally, LTP at this synapse is NMDAR-dependent. Using an NMDAR antagonist (D-APV), we were unable to induce LTP, and once D-APV was washed out, LTP was inducible. Future *ex vivo* experiments will test the common properties between natural odor preference learning and *in vitro* LTP mechanisms.

Title: Sleep-promoting doses of Diazepam, Eszopiclone and Zolpidem disrupt Rhesus macaque memory and attention as compared to DORA-22, a dual orexin receptor antagonist.

Abstract: Approximately 10% of the adult population experiences insomnia, with 1/3 of sufferers seeking pharmacotherapy intervention in order to treat their symptoms. A novel mechanism is represented by the orexinergic system which plays a critical role in the regulation of sleep/wake cycles. In an effort to develop medications with improved tolerability we have identified a potent and selective dual orexin receptor antagonist, DORA-22. In the current study we have compared the effects of the nonbenzodiazepine GABA-A receptor modulators Eszopiclone and Zolpidem, and the benozodiazepine Diazepam, to DORA-22 on short term recognition memory (delayed match to sample [DMS]) and sustained spatial attention (serial

choice reaction time [SCRT]) in rhesus macaques, using a novel in-cage touchscreen system. The doses of compounds tested in cognition assays were selected based on those shown to reduce active wake, a measure of sleep promotion, established by polysomograpgy. In the absence of a decrease in active wake the compounds were assessed up to the maximum dose at which monkeys would consistently work in cognitive tasks. At these doses, Diazepam, Eszopiclone and Zolpidem resulted in a disruption in recognition memory in DMS that was independent of delay. In marked contrast recognition performance was unaffected by DORA-22 at doses up to 30X greater than the minimum effective dose that reduced active wake. Similarly, administration of Diazepam, Eszopiclone and Zolpidem, at doses at, or below, the minimum effective dose reducing active wake, resulted in disrupted performance in SCRT that was marked at short, but not long, cue durations, indicative of impaired attention. DORA-22 was without effect on SCRT performance at 30X greater than the minimum effective dose in active wake. These preclinical data provide further evidence that DORAs may represent an important new strategy in the treatment of insomnia. Clinical studies are currently in progress to further understand the safety and efficacy of dual orexin receptor antagonists.

Title: Sleep-promoting doses of diazepam, eszopiclone and zolpidem more negatively impact novel object recognition memory in rat as compared to dual orexin 1 and 2 receptor antagonism.

Authors: *J. M. USLANER, D. M. EDDINS, X. WANG, S. J. TYE, S. V. FOX, C. E. CANNON, A. T. SAVITZ, J. BINNS, S. L. GARSON, L. YAO, R. HODGSON, J. BRUNNER, T. MCDONALD, P. L. TANNENBAUM, A. L. GOTTER, S. D. KUDUK, P. J. COLEMAN, C. J. WINROW, J. J. RENGER

Abstract: Approximately 10% of the general population suffers from chronic insomnia and 30% of insomniacs use pharmacotherapy. The current standards of care, including the nonbenzodiazepine GABA-A receptor modulators Eszopiclone and Zolpidem, may carry unwanted side-effects, including cognitive disruption. With the aim of developing better tolerated medications, we have identified dual orexin 1 and 2 receptor antagonists (DORAs), which promote sleep in preclinical species as well as in humans. Here we compared the effects of the GABA modulators Eszopiclone, Zolpidem, and the benzodiazepine Diazepam to a DORA on novel object recognition memory performance in rats. Doses of each compound tested were based on the ability to reduce active wake, as defined by electroencephalogram (EEG) and electromyogram (EMG). We report that in preclinical assays Eszopiclone, Zolpidem, and Diazepam disrupted recognition memory at doses well below those affecting active wake. In marked contrast, DORA-22 only disrupted novel object recognition performance at doses far exceeding those required to reduce wakefulness. Moreover, we found that the low doses of the GABA modulators that impacted recognition memory also decreased hippocampal ARC protein expression, which is involved in synaptic plasticity, whereas only very high doses of DORA-22 impacted ARC. These findings in two preclinical models suggest that DORAs may carry less risk associated with cognitive impairment than the current standards of care, which could have important implications for treating insomnia. Clinical studies are ongoing to understand the efficacy and safety profile of DORAs.

Title: Dissociating accounts of risk vs. salience encoding in the orbitofrontal cortex

Authors: *G. ESBER[1], S. SHAPIRO[2], A. HERNANDEZ[3], M. OGAWA[4], J. TRAGESER[5], T. STALNAKER[1], G. SCHOENBAUM[1]

Abstract: Several labs have reported that a subpopulation of OFC neurons responds more in anticipation of probabilistic than certain rewards. This finding has led to the proposal that OFC is involved in encoding of risk or uncertainty. We recently
investigated this hypothesis by recording the activity of OFC neurons while rats responded to four odor cues rewarded at 100%, 67%, 33%, or 0% probability. Consistent with prior reports, we found a population of neurons particularly
responsive in anticipation of uncertain reward (33% or 67% > 100% or 0%). However, these neurons also exhibited larger responses prior to certain reward than certain non-reward (100% > 0%) and prior to low than high probability
reward (33% > 67%). This asymmetrical pattern is poorly explained by risk or uncertainty accounts, for they predict that a similar neuronal response should have been observed in anticipation of the two certain outcomes (100% = 0%) as
well as the two probabilistic ones (33% = 67%). Interestingly, these results are precisely what would be expected by theoretical accounts of acquired salience. To further explore the contrasting predictions of risk vs. salience, here we conducted a variation of the above study in which activity of OFC neurons was recorded across two blocks of trials. In the first block, intended to replicate our previous findings, rats were trained to respond to five odor cues rewarded at 100%, 75%, 50%, 25%, and 0% probability. In the second, critical block, another set of five odors signaled the presentation of either of two equally valued rewards at 100%, 75%, 50%, 25%, and 0% probability. Notably, the cues in the second block should have the same salience as their counterparts in the first block, but equal risk. An analysis of the data will be presented that will dissociate risk- vs. salience-based hypotheses.

Title: Thyroid receptor beta is critically involved in the cognitive enhancing effects of nicotine, while thyroid receptor alpha1 is not

Authors: *P. T. LEACH[1], J. W. KENNEY[2], T. J. GOULD[1]
[1]Psychology/Neuroscience, Temple Univ., Philadelphia, PA; [2]Univ. of Southampton, Southampton, United Kingdom

Abstract: Cigarette smoking is common despite its adverse effects on health, including cardiovascular disease and stroke. Nicotine, the main psychoactive component of cigarette smoke, may contribute to the development of addiction by enhancing maladaptive drug-context associations. Nicotine may also have long-lasting detrimental effects on the endocrine system. Specifically, nicotine may increase thyroid hormone secretion, metabolism, and receptor activation. Low thyroid hormone levels in adulthood can confer memory deficits. Animal models of disrupted thyroid function suggest nicotine reverses the memory deficits associated with low hormone levels. Initial examination with Protein/DNA arrays (Panomics) identified hippocampal thyroid receptor activation during nicotine enhancement of hippocampus-dependent learning. The present work evaluates the contribution of thyroid hormone receptor β (TRβ) and thyroid hormone receptor α1 (TRα1) in the effect of nicotine on hippocampus-dependent memory using a contextual fear conditioning paradigm. It was hypothesized that TR would be important for the acute effects of nicotine on contextual fear conditioning, but it was unclear which receptor type would be critical. To determine the role of TRβ and TRα1 in the effects of nicotine on memory, mice lacking the TRβ and TRα1 gene (KOs) and their wildtype littermates (WTs) were administered acute nicotine prior to training and testing on contextual fear conditioning. Twenty-four hours after training, mice were returned to the training context and evaluated for freezing, a species-typical fear response, for 5 minutes and this was used as a measure of contextual fear memory. For TRβ mutants, WTs receiving nicotine froze significantly more than WTs receiving vehicle alone, while KOs receiving nicotine did not freeze more than those receiving saline. This demonstrates a critical role for TRβ in the acute effect of nicotine on hippocampus-dependent memory. For TRα1 mutants, WTs and KOs receiving nicotine froze significantly more than those receiving vehicle alone. The present study may inform novel treatment approaches to smoking cessation therapies. Future directions include the evaluation of the role for TRα1 and TRβ on the cognitive deficit associated with nicotine withdrawal.

Title: Neuronal activity of the monkey prefrontal cortex during observational learning

Authors: *F. ISBAINE[1], A. BELMALIH[2], M. DEMOLLIENS[2], A. BROVELLI[3], M. MEUNIER[4], D. BOUSSAOUD[2]
[1]Inst. De Neurosciences Des Systèmes - INS -UMR INSERM 1106, MARSEILLE, France; [2]1 Inst. des Neurosciences des Systèmes, UMR1106-INSERM & Aix-Marseille Univ., Marseille, France; [3]Inst. de Neurosciences de LA TIMONE - INT-Aix-Marseille Université,, Marseille, France; [4]Ctr. de Recherche en Neurosciences de Lyon, CNRS UMR5292, INSERM U1028 & Univ. de Lyon, Lyon, France, LYON, France

Abstract: We have been investigating neuronal mechanisms of observational learning in monkeys. Two animals sitting in primate chairs, facing each other, executed a visuomotor task involving arbitrary associations between images and spatial targets (white squares) on a touch screen. Only one monkey had access to the touch screen at a time (actor). The other could only (observer). The monkeys alternated between the actor and observer role. The actor initiated a trial by placing his hand on a white rectangle located near his chest. Then a visual cue appeared together with 2 or 4 targets. Pressing the correct target led to a success signal (green ring), which was followed by a reward (a drop of fruit juice) after a delay. Incorrect response led to an error signal (red ring) and no reward was given. Single neurons and local field potentials (LFPs) were recorded from the dorsolateral prefrontal cortex (DLPF) of one monkey while he observed the other monkey performing two tasks: 1) learning by trial-and-error arbitrary visuomotor association; 2) learning after having previously observed the correct and incorrect associations made by the actor. In a previous abstract (Belmalih & al, 2010), we have shown that feedback-related activity of DLPF single neurons varied across experimental conditions: observation, learning after observation (LeO), trial-and-error learning or execution of a familiar task. Here, we analyzed the LFPs from 61 recording sessions to determine variations of neural activity across conditions at the population level. Event related potentials (ERP) and event related

spectral perturbations (ERSP), aligned on the presentation of correct and incorrect visual feedbacks were analyzed. We found that the ERP and ERSP signals were modulated depending on the conditions. In particular, the temporal and spectral specificity of these signals was significantly different between the two main conditions, i.e. TE and LeO. These results provide additional evidence supporting the involvement of DLPF in observational learning.

Title: Relationship between tolerance to the cognitive enhancing effect of nicotine and nicotine withdrawal-related impairments in contextual conditioning

Authors: *T. J. GOULD, D. S. WILKINSON, M. D. ADOFF
Dept Psychol, Temple Univ., PHILADELPHIA, PA

Abstract: Nicotine addiction is a multifaceted disease that can be influenced by several factors. Nicotine modulates various types of learning and memory and the ability of nicotine to alter cognitive processes may contribute to its addictive liability. Acute nicotine enhances contextual conditioning in mice, tolerance develops to this effect with chronic administration, and withdrawal from chronic nicotine impairs contextual conditioning. While tolerance and withdrawal-induced learning impairments both occur following chronic nicotine administration, it is unknown if they share similar or separate mechanisms. The present series of experiments were designed to provide evidence that tolerance and withdrawal are dissociable. C57BL/6J mice

were implanted with osmotic minipumps that delivered constant nicotine or saline for various durations and then were trained and tested in contextual conditioning either during chronic nicotine administration or 24 hours after pump removal. Chronic nicotine enhanced contextual conditioning in a dose- and time-dependent manner. Tolerance developed quickly to the enhancing effect of chronic nicotine. Furthermore, the duration of chronic nicotine treatment required to produce cognitive deficits upon cessation of treatment differed than that required to produce tolerance, which suggests that tolerance and withdrawal are mediated by separate mechanisms. The current findings add to the growing body of literature dissociating tolerance from withdrawal.

Title: Complex virtual environments for mongolian gerbils.

Authors: *C. LEIBOLD, J. HENKE, A. WÄTZIG, B. LUDWIG, J. HERMANN, C. TATARAU, K. THURLEY
Univ. of Munich, Planegg-Martinsried, Germany

Abstract: Virtual reality (VR) environments are becoming increasingly available to study spatial navigation in rodents. In many approaches so far spatial navigation did not go beyond simple open fields or linear tracks. How to make rodents learn to navigate in more complex environments is hardly investigated. We use a VR setup in which a spherical treadmill is placed inside a 360 degree toroidal screen onto which the virtual environment is projected. This design permits a fixation of the animal such that it can freely rotate around its vertical body axis. We trained gerbils (Meriones unguiculatus) to perform spatial tasks in virtual mazes of different complexity. First the animals learned to run back and forth between the two ends of a virtual linear track. At the ends they received a food reward. They had to learn to orient with only visual information and to avoid contact with the virtual walls. In this way they optimized the path from one reward location to the next. Performance increased within about 10 training sessions to almost optimal values: The animals avoided virtual walls and ran straight paths from one track

end to the other. Running speed was consistent with what is typically observed in real environments. When afterwards presenting more complex mazes such as U- or 8-shaped arenas the animals were able to transfer their previously acquired skills to the new tasks after only a few trials. Our behavioral setup can be straight-forwardly combined with extracellular recording techniques such as tetrodes.

Title: Cells in the primate hippocampus provide a timing signal for particular trial contexts.

Authors: *J. J. SAKON[1], S. WIRTH[2], Y. NAYA[1], W. A. SUZUKI[1]
[1]NYU CNS, New York, NY; [2]Ctr. de Neurosci. Cognitive, Univ. Lyon I, Bron, France

Abstract: Recent work from our lab has implicated the hippocampus in keeping track of time through incremental changes in neuronal firing rates during a temporal order memory task (Naya & Suzuki, *Science* **333** August 2011). This incremental timing signal is characterized by gradual increases or decreases in firing rate across a delay period between task-essential encoding events. Here we ask if incremental timing can be found during an object-place association task that is not contingent on temporal order memory. In this task (S. Wirth *et al*, *Neuron* **61** March 2009), monkeys were presented with one of two novel objects shown in one of two possible places on a computer monitor. Following a 700 ms delay period with only a fixation point on the screen, the subject was cued to release a bar during the presentation of either an orange circle (early release), or 500 ms later, a green circle (late release). All trials required visual fixation on a central fixation dot. Each day, the subjects learned that two of the four possible object-place combinations were associated with the early bar release while the remaining two were associated with the late bar release. Correct responses were always followed by juice reward. We analyzed 137 isolated hippocampal neurons with a firing rate greater than 1 Hz averaged across the delay interval of this task. We find a large group of cells (N=79) that display a gradual increase or

decrease in firing rate across the delay, indicating that incremental timing signal is present during this object-place task. These 79 cells are separated into two groups. Similar to the incremental timing signal initially described in the temporal order memory task, some of these cells (N=34/79) signal timing similarly for both early and late release trial types. A second group of cells (N=45/79) provide timing signals selective to particular trial contexts. Specifically, these latter cells show incremental timing signals selective to either early or late release trials during the delay. Similar contextual control of a hippocampal timing signal was also reported in rodents during the performance of an object-odor association task (MacDonald *et al, Neuron* **71** August 2011). Such a context-dependent incremental timing signal could contribute to differentiating between distinct episodic memories.

Title: Toward a fusion model of feature and spatial tactile memory in the Australian crayfish Cherax destructor

Authors: *F. W. GRASSO[1], M. EVANS[2], J. A. BASIL, X[1], T. J. PRESCOTT[2]
[1]Dept. of Psychology, Brooklyn College, CUNY, BROOKLYN, NY; [2]Dept. of Psychology, Sheffield Univ., Sheffield, England, United Kingdom

Abstract: Australian crayfish Cherax destructor (ACCD) use their haptic sense to navigate in enclosed spaces in the absence of visual input, use their mobile antennae to explore novel objects and remember, in some manner, the configuration of the surfaces in their environment. We report on parallel biological and robotic simulation studies intended to advance our understanding of the memory systems underlying this ability. We hypothesize that the Medial Protocerebrum (MPC), an unpaired, high-order central brain structure that receives highly processed perceptual information from all the cerebral sensory modalities and from the thoractic ganglia is a site for spatial memory processing. The two key streams of information useful for spatial mapping in ACCD, tactile input from the antennae and proprioceptive information from the legs (‘step-counting’ odometry) converge in the MPC. The control architecture of our CrayTouchBot (CTBR) robot models this neurobiological system. In previous cybernetic

research we demonstrated the plausibility of an interrupt-based cross-correlation (IBCC) mechanism using sensors mechanically fixed to the robot to account for some of the ACCD's spatial memory abilities: learning an arena's configuration by abstracting and recording series of wall contacts during thigmotaxis (wall-following) behavior. We extended those results using a pair of movable mechanical touch-sensors to inform both the IBCC and a second memory module to capture surface exploration ACCD behavior. Numerical correlation between the current sensor sweeps or 'antennation' sensation patterns (ASP) and stored previously experienced ASPs permit the classification of the current location as familiar or novel. In the CTBR control system the IBCC and the ASP memory systems share information to enhance each other's performance in its primary function: the positional confidence of the IBCC biases the ASP recall process and vice versa to arrive at combined recall readouts that use both forms of stored information and recognition. These in turn inform steering decisions in the CTBR during exploration. The combination of the ASP and IBCC memory systems is a novel computational approach that is constrained by the MPC connectivity. We report on animal and robot studies aimed at determining whether the behavior of the CTBR endowed with these interacting memory systems reproduces ACCD exploration behavior: thigmotaxis punctuated by episodes of antennation at surfaces containing tactilely inhomogeneous structures. Understanding such haptic memory systems might also be useful designing robotics applications where GPS and vision are not available for spatial guidance.

Title: Memory and social interactions in crayfish

Authors: N. JIMÉNEZ-MORALES[1], A. R. ESPINOZA[2], K. MENDOZA-ANGELES[1], G. ROLDÁN[2], *J. HERNANDEZ-FALCON[2]

Abstract: In crustaceans smell is the most important sensory cue for agonistic interactions and it has been proposed that memory is essential to maintain the hierarchical organization within a

given group. However, this kind of memory (which we will call agonistic memory) has not been characterized. How long this memory lasts? How is it consolidated? Is it related with sleep? These are the main questions that we approached in this work. Our first goal was to characterize this agonistic memory, but memory tests for crustaceans are scarce. Therefore we designed a set of experiments in order to investigate forgetting.
Hierarchy in crustaceans is stable in a given group as measured in repeated trials which may imply a clear role for memory. In these conditions, the intensity of interactions diminishes on a daily fashion, in a well described pattern. On these bases we performed experiments that disturb this progression in memory consolidation.
We used male adult crayfish, Procambarus Clarkii, triads in intermolt to evaluate social interactions. Agonistic interactions were videotaped for one hour in a circular arena for 5 consecutive days. We had two experimental groups. Group 1 animals received an injection of scopolamine (100 ng/g) after the fist interaction. Group 2 animals were cold anesthetized. A third group was injected with saline solution finally; a fourth group was a non manipulated control. Results show that scopolamine impairs long-term hierarchical organization in subsequent encounters. This is expressed as an increase in positive contacts, especially from the dominant subject, although, scopolamine did not modify the hierarchical organization established in the first encounter. Cold anesthesia also impaired the hierarchical organization in a similar way as scopolamine, though with less intensity. Surprisingly saline injection also seemed to produce forgetting, but this effect was slight and of short duration. These results suggest that the social status is learned and can be forgotten.

Title: Short term memory in the leg muscle control system of the stick insect Cuniculina impigra

Authors: *E. BERG, J. SCHMIDT, A. BÜSCHGES
Univ. of Cologne, Cologne, Germany

Abstract: Walking stick insects that do not find a foothold perform searching movements (SMs) with the respective leg (Bässler, 1993; Dürr, 2001). SMs are rather stereotypic, cyclic

movements. Here we explore changes in space and time in the SMs upon a one-time disturbance by an obstacle. Experiments were performed on stick insects (Cuniculina impigra) with a single intact foreleg that was restrained to move in the vertical plane. A stick was moved into the leg's movement path such that it was touched one time by the distal tibia. After touching, animals modified their SMs (i) by shifting them towards the position of disturbance and (ii) by significantly decreasing SM amplitude. These changes were independent of where in the leg's trajectory the stick was touched. Only slowly the movements shifted back to the original position accompanied by a simultaneous increase in amplitude. This targeted response outlasting a single stimulus for several seconds expresses properties of a sort of short term memory of the insect leg muscle control system.

We investigated the role of leg sense organs for the successful execution of the targeted motor response by means of ablation experiments: (i) no influence on SMs was detected following replacement of the tibia by a peg leg, i.e. following removal of sensory signals distal to the femur. (ii) SMs were impaired when proprioceptors reporting positions of femur and tibia were ablated.

In order to study the underlying changes in motor output leg muscle activity was monitored by EMG recordings from levator and depressor trochanteris. The ratio between the integrals of their muscle activity changed upon disturbance and was related to the direction of shift of SMs. Duty cycles and phase relations did, however, not change. Currently, we further explore the mechanism underlying the targeted response by intracellularly recording leg motor and premotor interneurons.

Title: Distinct traces for appetitive versus aversive olfactory memories in DPM neurons of *Drosophila*

Authors: *I. CERVANTES-SANDOVAL, R. L. DAVIS
Neurosci., The Scripps Res. Inst., Jupiter, FL

Abstract: The general logic used by the brain for differentially encoding positive and negative memories remains unknown along with how such experiences are represented by collections of memory traces at the cellular level. Here we compare the cellular memory traces that form in the dorsal paired medial (DPM) neurons of Drosophila after conditioning flies with odors associated with negative or positive unconditioned stimuli (US). Our results show that the appetitive DPM neuron trace is distinguished from the aversive trace in three fundamental features: (1) The DPM neurons do not respond to an appetitive US of sucrose by itself, in contrast to their robust response to an aversive US of electric shock. (2) The appetitive trace persists for twice as long as the aversive trace. (3) The appetitive trace is expressed in both neurite branches of the neuron, rather than being confined to a single neurite branch like the aversive trace. Aditionally, we demonstrate that training flies with non-nutritive sugars that elicit a behavioral memory that decays within 24 hr generates, like aversive conditioning, a short-lived and branch-restricted memory trace, whereas training with nutrient sugars generates non-decaying behavioral memory and the more persistent and cell-wide memory trace. These results indicate that the persistence and breadth of the DPM neuron memory trace influences the duration of behavioral memory.

Title: Dopamine is required for learning and forgetting in *Drosophila*

Authors: *J. A. BERRY[1,2], I. CERVANTES-SANDOVAL[1], E. P. NICHOLAS[1], R. L. DAVIS[1]
[1]The Scripps Res. Inst. Florida, Jupiter, FL; [2]Developmental Biol., Baylor Col. of Med., Houston, TX

Abstract: Psychological studies in humans and behavioral studies of model organisms suggest that forgetting is a common and biologically regulated process, but the molecular, cellular, and circuit mechanisms underlying forgetting are poorly understood. Here we show that the bidirectional modulation of a small subset of dopamine neurons (DANs) after olfactory learning regulates the rate of forgetting of both punishing (aversive) and rewarding (appetitive) memories. Two of these DANs, MP1 and MV1, exhibit synchronized ongoing activity in the mushroom body neuropil in alive and awake flies before and after learning as revealed by functional cellular

imaging. Furthermore, while the mushroom body-expressed dDA1 dopamine receptor is essential for the acquisition of memory, we show that the dopamine receptor DAMB, also highly expressed in mushroom body neurons, is required for forgetting. We propose a dual role for dopamine: memory acquisition through dDA1 signaling and forgetting through DAMB signaling in the mushroom body neurons.

Title: Uniform activation of postsynaptic cAMP responses by dopaminergic neurons in the *Drosophila* mushroom body

Authors: *S. M. TOMCHIK, R. L. DAVIS
Scripps Florida, Jupiter, FL

Abstract: Changes in cAMP are critical for olfactory associative learning, and cAMP signaling in the mushroom body (MB) is necessary for learning in *Drosophila*. Dopamine is believed to relay punishment signals to the mushroom body during olfactory classical conditioning, elevating cAMP to generate the plasticity underlying learning. In order to understand how dopamine activates cAMP, we imaged dopamine responses with a genetically encoded cAMP reporter in the *Drosophila* mushroom bodies *in vivo*. The thermosensitive TRPA1 channel was expressed in different subsets of afferent dopaminergic neurons that innervate the mushroom bodies. When stimulating each of these subsets of neurons, we observed increases in cAMP. These increases were observed across the vertical and medial mushroom body lobes. These data suggest that dopamine elevates cAMP in the mushroom body lobes in a uniform manner. Further experiments are needed to decipher how these responses are differentiated from those recruited during classical conditioning, where neuronal activity encoding the conditioned stimulus precedes or overlaps activation of dopaminergic pathways that signal the unconditioned (aversive) stimulus.

Title: Cross-modal memory transfer in *Drosophila*

Authors: *X. ZHANG[1], Q. REN[2], A. GUO[1,2]
[1]Inst. of Biophysics, Chinese Acad. of Sci., Beijing, China; [2]Inst. of Neuroscience, Chinese Acad. of Sci., Shanghai, China

Abstract: In animals, cross-modal plasticity happens universally when the inter-modal state meets the changing environment. Here, by using the sensory preconditioning (SP) paradigm, we investigated the cross-modal memory transfer in *Drosophila*. It was reported that the conditioned response to the reinforced olfactory/visual stimulus (S1) can be transferred to the unreinforced visual/olfactory stimulus (S2) [1]. Typically, the behavioral expression of memory retrieval was thought via S1-S2 association [2]. However, whether other associations to S2 exist in the SP is largely unknown.

The mushroom bodies (MBs) and the fan-shaped body (FB) of *Drosophila* are thought to form and reserve the short-term olfactory and visual memory, respectively. Firstly, we proved that the 247>*shibire* specifically impaired the olfactory memory retrieval, but left the visual elevation memory retrieval intact. Besides, c205>*shibire* specifically impaired the elevation memory retrieval but not the olfactory memory. It was indicated that the output of α/β lobes of MBs and the layer 5 of FB were indispensable for uni-modal olfactory and visual memory retrieval, respectively. Next, we investigated cross-modal memory transfer in both olfactory-visual (O-V) and visual-olfactory (V-O) directions.

In the O-V direction, the olfactory cues were reinforced by heat punishment (US) after unreinforced exposure to paired olfactory and visual stimuli. The response to visual cues was

then tested. We found that the conditioned response to visual stimuli cannot be impaired by blocking MBs, which was contradictory to the S2-S1-US assumption, because the memory recall through S1-US should be blocked here. Therefore, the S1-S2 association may be not the only way for S2 memory retrieval. The existence of S2-(US)-Response can be further supported by the fact that blocking FB left the memory retrieval in the V-O direction intact. On the other hand, MBs blocked impaired the conditioned response in the V-O direction. However, FB blocked left the O-V direction's memory retrieval intact. The asymmetric function of MBs and FB in the process of cross-modal memory transfer strongly suggested that the MBs may reserve the inter-modal associations. It can be supported by the results that dysfunction of MBs and FB simultaneously blocked the memory retrieval in both O-V and V-O directions.
In sum, we found the conditioned response to unreinforced cues can be recalled from parallel pathways rather than S1-S2 association; we also speculated the multi-function role played by MBs in the cross-modal memory transfer processing.

Title: The role of CASK and CaMKII autophosphorylation in regulation of synaptic growth, calcium signalling and associative learning

Authors: *J. J. HODGE, B. R. MALIK, J. M. GILLESPIE
Physiol. and Pharmacol., Univ. of Bristol, Bristol, United Kingdom

Abstract: CaMKII autophosphorylation at threonine 287 results in a kinase that is constitutively active and calcium independent. Synaptic mechanisms regulating CaMKII autophosphorylation are therefore central to neural plasticity and memory formation with disregulation of autophosphorylation being associated with a range of pathological states. One such CaMKII-regulatory molecule is CASK which when mutated in human causes a number of neurological

defects including mental retardation. CASK knock-out mice are lethal due to a cleft palate phenotype. *Drosophila* however has a highly conserved homologue of the single human CASK gene which when deleted is viable. We show removal of the CASK isoform that contains the CaMK-like and L27 domains (CASK-ß) results in larva with more numerous but smaller synapses at their neuromuscular junctions. These CASK-ß mutant synapses also had increased levels of CaMKII T287 autophosphorylation. Direct motorneuron expression of phospho-mimic CaMKII T287D also caused a similar increase in synapse number as the CASK-ß mutant with CASK overexpression returning the synapse number to wild-type levels. CASK mutants showed reduced activity dependent calcium (Ca^{2+}) signalling in motorneuron cell bodies and synaptic terminals accompanied by a reduction in vesicle recycling. Reduction in CASK and T287D overexpression both gave a similar reduction in Ca^{2+} signalling with CASK overexpression partially returning Ca^{2+} signalling to normal levels consistent with CASK and CaMKII acting in a common pathway controlling activity dependent Ca^{2+} signalling and synaptic growth. We also show CASK mutant larvae have reduced olfactory associative learning, which localised to the mushroom body with targeted reduction of CASK in these neurons causing a reduction in odour induced Ca^{2+} response. In adults, CASK mutation removes short- and long-term memory, with CASK function in the mushroom body α' and ß' neurons being required for its role in memory. Likewise directly changing the levels of CaMKII autophosphorylation in these neurons similarly reduced short- and long-term memory. Therefore CASK regulates CaMKII autophosphorylation in a pathway required for memory formation involving activity dependent changes in Ca^{2+} signalling in the mushroom body α' and ß' neurons.

Title: Nuclear gating of *Drosophila* CREB in response to environmental stimuli

Authors: *R. A. FROPF[1], T. C. TUBON, Jr[2], J. C. P. YIN[1]
[1]Genet., Univ. of Wisconsin Madison, Madison, WI; [2]Biotech., Madison Area Tech. Col., Madison, WI

Abstract: CREB (cAMP Response Element Binding protein) is a crucial transcriptional regulator of numerous nervous system processes. The Drosophila homolog of CREB, dCREB-2, has well-described roles in sleep, homeostasis, memory formation, and neurodegenerative diseases. Additionally, different protein isoforms of the dCREB2 gene have been shown to have differential effects on these processes. Here, we generated antibodies against specific dCREB2 isoforms to investigate the activity and subcellular localization of these different protein species. We found that these antibodies reveal dramatically different cellular localization of protein isoforms in both fly brains and cultured Drosophila Schneider cells. While at baseline, the majority of dCREB2 protein is located outside the nucleus, relevant stimuli, such as serum starvation in cells and memory formation in flies, can change these localizations. These results indicate that dCREB2 localization is an important component to an organism's response to its environment. Understanding this process may provide a more mechanistic picture for how these responses are mediated and regulated during dCREB-2's participation in adaptive responses.

Title: Two subsets of mushroom body neurons are required to retrieve olfactory memory in *Drosophila*.

Authors: *Z. XIE[1], Y. ZHONG[2]
[1]Beijing, China; [2]Cold Spring Harbor Lab., New York, NY

Abstract: The identification of neural ensembles involved in memory retrieval is crucial for understanding the mechanism of memory processing, and memory deficiency displayed in many neurological diseases. Mushroom body is a core place for olfactory memory processing. To

further identify the mushroom body neural ensembles involved in memory retrieval, we examined the roles of various subsets of mushroom body neurons in olfactory 3h memory retrieval. Our results revealed that the retrieval of aversive and appetitive 3h memories required the synaptic outputs from two subsets of mushroom body neurons. Thus, in *Drosophila* mushroom body, both aversive and appetitive 3h memories are retrieved through two routes. Using at least two routes to retrieve memory may serve as an evolutionary conserved strategy during memory processing.

Title: Octopamine plays a role in the proboscis extension response (PER) of honeybees (Apis mellifera)

Authors: C. BUCKEMÜLLER, R. ZEUMER, *D. EISENHARDT
Bio, Chem, Pharm, Freie Univ. Berlin, Berlin, Germany

Abstract: Octopamine, a biogenic amine, is most likely to play an important role as a neurotransmitter, a neuromodulator and a neurohormone in invertebrates. It is important for different behaviors, i.e. aggression, egg-laying and walking. It also plays a crucial role in appetitive learning in Drosophila and honeybees. However, the precise mechanisms are unknown. Therefore, we here aim towards understanding the dependency of learning and memory formation and octopamine in honeybees.
We present data on the role of octopamine in eliciting the proboscis extension response (PER). During classical appetitive conditioning of harnessed honeybees, the PER serves as the unconditioned response (UR). Therefore it is crucial to understand the role of octopamine in eliciting the PER before asking about its impact on olfactory conditioning in honeybees.
In our experiments we predominantly used epinastine, which has been demonstrated to antagonize octopamine receptors in honeybees (Roeder et al., Eur J Pharmacol, 1998, 349, 171-177). We first determined the median lethal dose (LD 50) of systemically injected epinastine to find out about the appropriate epinastine concentration to work with.
Following this analysis we studied the impact of octopamine on the PER. First we asked if

epinastine interferes with the PER depending on the concentration of sucrose used to elicit the response. Three different concentrations of sucrose were used to elicit the PER and the impact of systemically injected epinastin on the PER rate was tested. In a second experiment we asked if epinastin effects the animals' motivation to elicit their proboscis. We compared hungry and satiated bees that were injected with epinastine.
Our experiments suggest that in honeybees octopamine modulates the proboscis extension response according to the animals' motivational status. Further experiments will reveal if this octopamine-dependent modulation of the PER plays a role in learning and memory formation.

Title: How are reward experiences translated into memory?

Authors: *K. MARTER, D. EISENHARDT
Freie Univ. Berlin, Berlin, Germany

Abstract: In appetitive classical conditioning the presentation of a conditioned stimulus (CS) precedes the presentation of an unconditioned stimulus (US), i.e. the reward. An animal learns the association between the previously neutral CS and the reward and reacts with a conditioned response (CR) when the CS is presented. Thus, an animal learns that the previously neutral CS predicts the occurrence of the reward. The term associative strength describes the extent to which the CS predicts the reward and it is generally accepted that the associative strength is mirrored in the CR during acquisition (Rescorla & Wagner, 1972).
A recent study in honeybees demonstrates a correlation between the reward duration during classical conditioning and the susceptibility of a long-term extinction memory for protein synthesis inhibition (Stollhoff & Eisenhardt, 2009). Rescorla and Wagner (1972) proposed an impact of the reward magnitude on the associative strength, i.e. the CR. Although the reward duration might be interpreted as an aspect of the reward magnitude, a "Rescorla & Wagner like" correlation between the CR during acquisition and the reward duration was not observed by Stollhoff & Eisenhardt (2009). A reason for the contradiction between this previous result and the proposed outcome might be the fact, that only the occurrence of the PER was recorded,

resulting in dichotomous data.
Therefore, we here aim to further elucidate the impact of the reward duration on the associative strength gained during acquisition but also on long-term memory (LTM) formation.
We study this problem in classical olfactory conditioning of the proboscis extension response (PER) in harnessed honeybees (Apis mellifera) by analyzing the animals behavior and by quantifying the activity of the proboscis extending muscle M17. Moreover behavioral pharmacology is used to study the impact of the reward duration on the biochemical mechanisms underlying the formation of LTM.
Our analyses demonstrate that the reward duration has no impact on the CR during acquisition and long-term memory retention 24 h later. However, the resistance to extinction observed 24 h after acquisition differs after conditioning with different reward durations. In addition, the sensitivity of the LTM to protein synthesis inhibition is affected by the reward duration. This suggests a dependency of the memories strength and the molecular mechanisms underlying memory formation on the duration of the reward presented during acquisition, although the CR during acquisition is not affected.

Title: A role of protein degradation in memory consolidation after initial learning and extinction learning in the honeybee (Apis mellifera)

Authors: *J. FELSENBERG[1], V. DOMBROWSKI[2], D. EISENHARDT[1]
[1]Neurobio., [2]Biochem., Freie Univ. Berlin, Berlin, Germany

Abstract: In classical conditioning animals learn the association between a conditioned stimulus (CS) and an unconditioned stimulus (US) and form a memory about this association. Retrieving a CS-US memory multiple times results in a decrease of the CR, which is termed extinction. During extinction learning the animals learn that the previously learned CS-US association no longer holds true. Accordingly, an extinction memory is formed about a CS-noUS association. Extinction memories undergo, like the initial memory, a consolidation process resulting in a long-lasting and stable extinction memory. The formation of this consolidated extinction memory has recently been shown to dependent on protein degradation and it has been proposed

that protein degradation is necessary to destabilize the extinguished CS-US memory to enable the formation of the CS-noUS memory. Here we test this hypothesis to further understand the mechanisms involved in extinction memory formation.
Using a classical appetitive conditioning paradigm in the honeybee (Apis mellifera) we demonstrate that an inhibitor of protein degradation, MG132, interferes with long-term memory formation after extinction learning, thereby supporting previous findings in vertebrates. However, we also show that the application of MG132 enhances long-term memory formation after initial learning, i.e. in a situation were no pre-existing memory has to be destabilized. These results support the idea that MG132 inhibits protein degradation during formation of a long-term memory rather than destabilizing an existing memory trace. In addition, we demonstrate that the sensitivity of memory formation after initial learning and extinction learning to MG132 depends in the same way on the number of CS-US trials and the inter-trial interval applied during initial learning. We conclude from these results that the learning parameters during acquisition are critical for memory formation after extinction. Thus protein degradation in both learning processes might be functionally linked.
We next asked what protein degradation system might be responsible for the behavioural effects. We demonstrate that MG132 blocks the proteasome in honeybee brain tissue as does a specific inhibitor of the ubiquitin-proteasome system, clasto-Lactacystin β-lactone (β-lac). β-lac injection after initial learning enhances memory formation in the same way as MG132 does. These results support the notion that proteasome-mediated protein degradation is inhibited by MG132 and restricts long-term memory formation in honeybees.

Title: Mapping reward pathways in the honey bee brain by gene induction

Authors: *M. MCNEILL[1,2], A. BROCKMANN[1,2], T. MCGILL[1], G. E. ROBINSON[1,2,3]
[1]Dept. of Entomology, Univ. of Illinois At Urbana-Champaign, Urbana, IL; [2]Neurosci. Program, [3]Inst. for Genomic Biol., Univ. of Illinois at Urbana-Champaign, Urbana, IL

Abstract: Circuits that mediate perception of reward, collectively known as the reward system, add salience to some of the essentials of life: food and reproduction. Solitary insects collect rewarding foods to benefit their own nutritional and reproductive needs, while eusocial insects, such as honey bee foragers (*Apis mellifera*), collect rewarding food resources to share with their nest mates. Thus, the altered behavioral response to rewarding food sources may indicate that the reward system has been co-opted during the evolution of social behavior. To begin to understand how the reward system may have been co-opted by the transition from “me to we,” we first wanted to identify neurons responsive to reward. To identify those neurons, we either allowed bees to fly to and collect a food reward, or we provided them with a food reward in a laboratory setting. We collected brains from several hundred individuals immediately after they had received the reward and at several subsequent time points. We processed the brains for fluorescent mRNA *in situ* hybridization targeting the broadly expressed immediate early gene, *c-jun*, which served as a marker for neuronal activation. We then imaged whole brains using confocal microscopy, and registered brain images onto a standardized honey bee brain model in 3D space so that the location of a voxel (3D pixel) in one image stack represented a voxel in every subsequent image stack. Significant changes in voxel intensity across conditions and time ponts represented differential neuronal activation. We detected changes in *c-jun* expression in a pair of cells in the dorsal posterior protocerebrum, which co-express a marker for dopamine synthesis, *tyrosine hydroxylase*. We also detected *c-jun* expression level changes in sub-populations of intrinsic and extrinsic mushroom body Kenyon cells. Our results provide a framework for future studies on the neurobiological and molecular basis of reward-based behavior in honey bees.

Title: Learning to navigate: Exploratory orientation flights of young honeybees

Authors: *J. DEGEN[1], A. KIRBACH[1], K. LEHMANN[1], R. MENZEL[1,2]
[1]Dept. of Neurobio., Freie Univ. Berlin, Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci. (BCCN), Berlin, Germany

Abstract: Honeybees (Apis mellifera) perform exploratory orientation flights to learn how to return safely to their hives. Path integration and learning of landmarks are thought to contribute to a safe return but the role of landmark learning is still not known. In order to investigate whether landmarks are learned in spatial relation to the hive we analysed the patterns of consecutive orientation flights applying the harmonic radar technique for tracking the complete flight paths of individually marked bees. A total of 266 orientation flights of 167 bees were analysed. Usually bees explore different regions around the hive in consecutive orientation flights but bees may also deviate from this pattern. Consequently the first foraging flight may not lead into an area they had explored before. To investigate the role of landmark learning we excluded the use of path integration by displacing the bees after their very first orientation flight and found that bees displaced into the explored area returned back to the hive significantly faster than when displaced into an unexplored area. In control experiments we proved that bees were unable to return to the hive if they did not perform at least one orientation flight. We conclude that bees learn the spatial relations of landmarks relative to the hive during their very first exploratory orientation flights, and odors emanating from the hive can be excluded as a guiding signal.

Title: Searching for neural correlates of decision making in honeybees

Authors: *H. ZWAKA[1], R. MENZEL[1,2]
[1]Dept. of Neurobio., Freie Univ. Berlin, Berlin, Germany; [2]Bernstein Ctr. for Computat. Neurosci. (BCCN), Berlin, Germany

Abstract: The focus of our work is the search for neural correlates of decision making in honeybees learning to navigate in a virtual environment. We record multiple units of mushroom

body (MB) extrinsic neurons in behaving animals.
The MB, a higher-order integration center in the insect brain, is known to be involved in the consolidation of memory and retrieving memory. MB extrinsic neurons are expected to recode the sensory input according to its value, and thus we expect neural read-out from the MB to be involved in decision making after operant learning.
We achieve long lasting extracellular recordings from multiple MB extrinsic neurons in animals controlling their visual environment by the movement of an air supported ball. The visual environment consists of differently colored objects whose virtual distance is indicated by their different parallax. In addition the ground structure below the animal and the pattern of an UV illuminated polarization pattern above it provides the honeybee with information about its movements. Animals are trained in the virtual environment (VE) to choose selected objects or routes. Depending on the particular organization of the virtual environment the animal can e.g. solve simple learned tasks or more complex, navigation-like tasks. In some of our experiments we use bees that were first trained in free flight and than introduced into the VE presenting corresponding visual patterns. We find preceding neural activities related to behavioral decisions.

Title: In search of the transmitters of Kenyon cells in the mushroom body of the honey bee

Authors: *R. BARTELS[1], S. VOIGT[2], R. MENZEL[1,3]
[1]Neurobiologie, AG Menzel, Freie Univ. Berlin, Berlin, Germany; [2]Univ. Potsdam, D14469 Potsdam, Germany; [3]Bernstein Ctr. for Computat. Neurosci., Berlin, Germany

Abstract: The insect brain is widely used to study neural circuits. Honey bees in particular are able to integrate and store a wide range of sensory information. The mushroom body (MB) is a central neuropil structure and crucial for the neural networks underlying these capabilities. A major limitation in analyzing the function of the MB is the lack of knowledge about the transmitters of MB intrinsic neurons, the Kenyon cells. Immunocytochemistry revealed a range of small peptides and glutamate. Furthermore, immunoreactivity was found against taurin.

Kenyon cells converge on extrinsic neurons (EN). We search for the transmitters of Kenyon cells by extra- and intracellular recordings from ENs combined with pharmacological manipulations. We found increases and decreases of spontaneous activity when manipulating NMDA-like receptors. In addition we saw changes of spike amplitude and stimulus dependent changes. Currently we perform experiments in which Kenyon cells are stimulated under various pharmacological treatments.

Title: Ionic current modulation of honeybee mushroom body and antennal lobe neurons

Authors: *S. HIMMELREICH, B. GRÜNEWALD
Goethe Univ., Frankfurt, Germany

Abstract: The honeybee (*Apis mellifera*) is a model organism for the study of learning and memory formation and its underlying cellular mechanisms. The neuronal pathway for associative olfactory learning includes two neuropils: the antennal lobes and the mushroom bodies. Here, the excitatory cholinergic pathway and the octopaminergic reward pathway converge. For learning-related plasticity, the coincident occurrence of the conditioned stimulus (CS) and the reward (unconditioned, US) has to be detected by the nervous system.
We performed patch-clamp recordings and cell calcium (Ca^{2+})-imaging to investigate the cellular interactions of the nicotinic acetylcholine receptor (nAChR) system and the octopamine receptor system of antennal lobe neurons and mushroom body intrinsic Kenyon cells *in vitro*. Patch-clamp experiments showed ACh-induced excitatory currents in antennal lobe and Kenyon cells. Co-application of ACh and biogenic amines (10µM octopamine or 10µM serotonin) revealed reversibly decreased currents. Also currents in antennal lobe neurons were reduced by co-applications of ACh and the adenylyl cyclase activator forskolin (10µM). This indicates involvement of a cAMP-dependent signaling cascade.The Ca^{2+}-imaging experiments have shown that biogenic amines(octopamine and serotonin, both 1µM) evoked Ca^{2+}-transients in antennal lobe neurons and Kenyon cells. Octopamine-induced transients were blocked by the antagonist mianserin (100µM). Co-applications of ACh (100µM) and the two biogenic amines octopamine

and serotonin (both 1µM) reduced Ca^{2+}-signals. The same was observed during co-applications of ACh and forskolin (10µM).Due to these findings, we postulate two possible cellular coincidence detectors between the cholinergic CS pathway and the reward (US pathway) during olfactory learning. These detectors may modulate further the incoming stimuli: (1) The activation of a calcium (Ca^{2+}) -dependent kinase which may be activated by an elevated intracellular Ca^{2+}-concentration induced by the coincident activation of the nAChR and an α-adrenergic-like octopamine receptor, AmOA1. (2) The possible phosphorylation of the nAChR by a cAMP-dependent protein kinase (PKA) triggered by β-adrenergic-like octopamine receptor activation. Both assumptions would lead to modulations of ACh-induced ionic currents as observed in our experiments. They may indicate coincidence mechanisms during olfactory learning. However, further experiments to unravel the cellular bases of learning related synaptic plasticity are in progress.

Title: The effects of maturation and foraging experience on behavioural flexibility and the mushroom bodies of bumblebees (Bombus impatiens)

Authors: *C. G. STRANG, A. P. NGO, D. F. SHERRY
Dept. of Psychology, Univ. of Western Ontario, London, ON, Canada

Abstract: Bees' impressive ability to learn about their environment and form associations has been extensively studied. Much less is known about how bees adapt their behaviour to a changing environment. Bumblebees use a flexible sampling strategy at the outset of foraging, but eventually establish 'flower constancy'. Coincident with this change in natural foraging behaviour, the mushroom bodies - a structure in the invertebrate brain linked to learning - increase in volume. Both age and experience are thought to influence total mushroom body size. We tested laboratory housed bumblebees (Bombus impatiens) of varying ages and foraging experience on a serial reversal task to assess the relationship between maturation, experience,

and behavioural flexibility. We predicted that increased age and experience would both decrease behavioural flexibility. The serial reversal task required bees to learn a colour discrimination and repeatedly reverse their pattern of responding when reward contingencies were reversed. Bees completed an initial discrimination session and three reversals. Foraging bees were classified at the time of testing as either low experience (0-3 days foraging) or high experience (5-8 days foraging). Brains were collected immediately following testing and the volume of the mushroom bodies correlated with serial reversal performance, allowing us to directly measure the relationship between mushroom body size and behavioural flexibility. Older bees (with larger mushroom bodies) were less behaviourally flexible than younger bees and age was found to influence behavioural flexibility more than foraging experience. These findings are consistent with our predictions based on the natural foraging behaviour of bumblebees.

Title: Neuroplasticity and mushroom body egr expression in honey bees

Authors: *C. C. LUTZ[1], E. E. MURDOCH[2], G. E. ROBINSON[1,3,4]
[1]Neurosci. Program, [2]Psychology Dept., [3]Inst. for Genomic Biol., [4]Dept. of Entomology, Univ. of Illinois At Urbana-Champaign, Urbana, IL

Abstract: Honey bees (Apis mellifera) learn to navigate in the environment surrounding the hive by performing “orientation” flights for several days before they begin to forage. Honey bee mushroom bodies (a paired region of the insect brain involved in learning) show both experience-expectant and experience-dependent changes in neuropil volume, coincident with the increased cognitive demands of orientation flights and foraging behavior. We previously reported that orientation flights trigger in the mushroom bodies a rapid and transient upregulation of egr, a homolog of egr-1, an immediate-early gene well known to respond to novel experience. Egr-1 also exhibits higher basal levels in brain regions undergoing development or remodeling in vertebrates; we therefore hypothesized that an increase in basal egr mushroom body expression

occurs at the age when bees take orientation flights. Laboratory-reared bees showed increased mushroom body basal egr expression at 4-6 days in comparison with earlier and later time points. This timing is consistent with the possibility that egr supports pre-foraging mushroom body neuropil growth. In addition, comparison of these results with egr expression dynamics under natural conditions suggested an association between egr expression and onset of foraging behavior, again consistent with a role for this gene in mushroom body neuropil expansion. These findings suggest that egr is involved in the acquisition and consolidation of spatial memory. Further studies of honey bees have the potential to extend understanding of the functional role of egr-related pathways in adult neuroplasticity.

Title: Identity discrimation in bumblebee colonies

Authors: *M. F. BROWN, J. M. SAYDE
Psychology, Villanova Univ., Villanova, PA

Abstract: Four colonies of bumblebees (*Bumbus impatiens*) were trained to respond differentially to visual displays consisting of either two identical stimuli or two different stimuli. The stimuli were either two colors (two colonies) or two line orientations (two colonies). Discriminative responses were defined by flying to an area on either the left or right side of the display, with one side correct during a "same" display and the other correct during a "different" display. A correct choice resulted in access to sugar solution. Following training, the colonies were tested with the alternative (novel) stimulus set, under conditions of non-differential reinforcement. All four colonies showed transfer of the discrimination in a manner consistent with control by a same/different concept.

Title: Dissociable effects of dopamine antagonists and cannabinoid CB1 antagonists: studies using the concurrent progressive ratio/chow feeding task

Authors: *P. A. RANDALL[1], E. J. NUNES[1], M. PARDO[2], B. KHAN[1], P. SHAH[1], C. A. LEE[1], V. K. VEMURI[3], A. MAKRIYANNIS[3], Y. BAQI[4], C. E. MÜLLER[4], M. CORREA[1,2], J. D. SALAMONE[1]

Abstract: A number of behavioral tests have been developed to assess effort-based choice behavior in rats, including a T-maze barrier choice task, discounting tasks, and operant procedures. One widely employed paradigm is the concurrent fixed-ratio 5 (FR5)/chow feeding choice task, in which rats can either lever press on a FR5 schedule for a preferred high-carbohydrate food, or approach and consume a less-preferred chow that was freely available in the chamber. Manipulations that interfere with dopamine (DA) transmission cause animals trained on this task to shift their behavior away from the effortful task of lever pressing and towards the consumption of the freely available chow. More recently, a new task has been developed in which the FR5 work requirement has been replaced with a progressive ratio (PROG) lever pressing requirement. Initial studies showed that the DA antagonist haloperidol decreased PROG lever pressing and maximum ratio achieved, but did not decrease chow consumption. This differed from the effects seen with the cannabinoid CB1 antagonist/inverse agonist and putative appetite suppressant AM251, which decreased both lever pressing and chow intake. This demonstrated that the effects of DA antagonism are not the result of a decrease in appetite or food motivation. The present work studied several additional manipulations, including more selective DA antagonists and additional CB1 antagonists/inverse agonists, using the PROG/chow feeding choice procedure. The first set of experiments studied the effects of the DA D1 antagonist ecopipam and the D2 antagonist eticlopride. Both drugs decreased number of lever presses and maximum ratio achieved while leaving chow consumption unaffected. Moreover, the adenosine A2A antagonist MSX-3 reversed the effects of eticlopride on PROG responding. Additional experiments studied the effects of cannabinoid CB1 antagonist/inverse

agonists. Unlike DA antagonists, these compounds produced profound reductions in chow intake at doses at or below those that suppressed lever pressing. These results indicate that an adenosine A2A antagonist is capable of reversing the impairments induced by a DA D2 antagonist on this procedure. Moreover, the effects seen with DA D1 and D2 selective antagonists differ substantially from those seen with appetite suppressants and pre-feeding, further demonstrating that the decrease in PROG lever pressing produced by DA antagonism is not the result of a decrease in appetite, primary food motivation or the unconditioned reinforcing properties of food.

Title: Development of rodent models of the motivational symptoms of depression: The catecholamine depleting agent tetrabenazine affects effort-related decision making in the concurrent FR5/chow choice task.

Authors: *E. J. NUNES[1], P. A. RANDALL[1], C. FREELAND[1], E. HART[1], C. E. MÜLLER[2], Y. BAQI[2], M. CORREA[1,3], J. D. SALAMONE[1]
[1]Psychology, Neurosci. Grad. Program, Storrs mansfield, CT; [2]Pharmazeutische Chemie, Univ. Bonn, Bonn, Germany; [3]Univ. of Jaume I, Castelló, Spain

Abstract: Mesolimbic dopamine (DA), particularly within the nucleus accumbens, has been shown to be a critical component of the brain circuitry regulating behavioral activation and effort-related processes. Interference with accumbens DA alters response allocation in choice procedures that involve cost/benefit evaluations of reinforcement value and response costs. Several behavioral tests have been developed to assess effort-based choice behavior in rats,

including maze procedures and operant tasks. The concurrent FR5/chow feeding choice procedure developed by our laboratory is a frequently used task. With this task, rats can lever press for a more preferred food or consume the less palatable freely available laboratory chow. Under baseline or control conditions, rats spend most of their time lever pressing for the more preferred food and eat very little of the chow. Accumbens DA depletions or administration of DA D1 or D2 family antagonists produce a shift in choice behavior, decreasing lever pressing and increasing chow intake. It has been suggested that these drug-induced shifts in effort-based choice that are seen in animals could be analogous to symptoms such as psychomotor retardation, anergia, and fatigue, which can be observed in individuals with depression, parkinsonism, and other disorders. For that reason, the current studies investigated the effects of the catecholamine depleting agent tetrabenazine (TBZ) on effort-related choice behavior using the concurrent FR5/chow feeding choice procedure. TBZ inhibits the vesicular monoamine transporter 2 (VMAT-2), and is used to treat Huntington's disease. Considerable evidence indicates that the vast majority of VMAT-2 binding in nucleus accumbens and striatum is on DA terminals, and that TBZ depletes DA. Moreover, TBZ has been shown to produce depressive side effects in some patients, including motivational symptoms such as psychomotor slowing, anergia, and fatigue. In rats tested on the concurrent FR5/chow procedure, TBZ (0.25-1.0 mg/kg IP) decreased lever pressing and increased chow consumption. Initial evidence indicates that these effects of TBZ on effort-related choice behavior can be reversed by co-administration of the adenosine A2A antagonist MSX-3 as well as the well established antidepressant bupropion. Taken together, these results demonstrate that administration of low doses of TBZ can alter effort-related choice behavior, biasing animals towards low effort alternatives. The present research may contribute to the development of novel treatments for effort-related motivational symptoms in humans.

Abstract: Dopamine plays a dual role in decision-making: on one hand, it is widely observed to signal anticipation of future rewards and reward prediction errors, but on the other, it is associated with the invigoration of actions that lead to a reward. This dual involvement of dopamine in signalling valence and action may lie at the heart of behavioural anomalies such as are observed when action and valence are orthogonally manipulated during learning. We saw that healthy human participants found it more difficult to learn to withhold an action to obtain a reward (so called no-go-to-win) than to emit an action to obtain a reward (so called go-to-win), or to withhold the action to avoid punishment (so called no-go-to-avoid losing). Here we assessed pharmacological and genetic basis of this anomaly, using levodopa to increase dopamine levels, and looking at well-described single nucleotide polymorphisms that selectively affect dopamine function in the prefrontal cortex (COMT) or the indirect pathway in the striatum (DRD2). Contrary to expectation, we found that boosting dopamine levels improved performance in the no-go-to-win condition. This effect was also expressed by variability in the COMT gene: participants carrying the met allele, which is associated with higher dopamine levels in the prefrontal cortex, performed better in the no-go-to-win condition. Finally, whereas subjects with different DRD2 genotypes performed equally well on average, we detected an interaction between COMT and DRD2 genotypes such that dopamine signalling in the indirect pathway in the striatum is counterbalanced by dopamine signalling in the prefrontal cortex. These results show that the dominant effect of dopamine during learning is to facilitate a decoupling between action and valence which is likely to depend on the prefrontal cortex. On the other hand, we provide evidence that dopamine in the striatum may have the opposite effect. These data help refine our understanding of the role of dopamine in behavioral control.

Title: Phasic dopamine release in the nucleus accumbens in response to ultrasonic vocalizations serving a pro-social communicative function in rats

Authors: *M. WÖHR[1], A. TOSE[2], M. J. WANAT,[2], A. S. HART[2], N. G. HOLLON[2], P. E. M. PHILLIPS[2], R. K. W. SCHWARTING[1], I. WILLUHN[2]
[1]Philipps-University of Marburg, Marburg, Germany; [2]Departments of Psychiatry & Behavioral Sci. and Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Rats emit distinct types of ultrasonic vocalizations (USVs), which serve as situation-dependent affective signals. Juvenile and adult rats produce 50-kHz USVs in appetitive situations such as rough-and-tumble play (Knutson et al., 1998), whereas 22-kHz USVs occur in aversive situations such as social defeat (Kroes et al., 2007). While 50-kHz USVs induce social approach behavior in the recipient, supporting the notion that they serve as social contact calls, 22-kHz USVs lead to freezing behavior, indicating an alarming function (Wöhr & Schwarting, 2007). These opposite behavioral responses are paralleled by distinct patterns of brain activation; with 22-kHz USVs inducing activation in amygdala and periaqueductal gray, both implicated in the regulation of anxiety and fear, whereas 50-kHz USVs evoke neuronal activation in the nucleus accumbens (NAcc; Sadananda et al., 2008). The NAcc is strongly implicated in appetitive behavior, which is critically modulated by dopaminergic input that encodes reward and reward-predicting stimuli. Therefore, we hypothesized that NAcc dopamine signaling is involved in social approach towards pro-social 50-kHz USVs and tested whether 50-kHz USVs elicit phasic dopamine release in NAcc using fast-scan cyclic voltammetry. Rats were exposed to playback of four acoustic stimuli: 1) 50-kHz USVs; 2) 22-kHz USVs; 3) time- and amplitude-matched white noise; 4) background noise. At the beginning of the experiment, all rats were exposed to white noise to reduce novelty. Then, rats were repeatedly exposed to sequences of all four stimuli in random order. Consistent with previous studies, social approach behavior and ultrasonic calling were evoked exclusively in response to 50-kHz USVs. Paralleling the behavioral effects, phasic dopamine release was only observed during playback of 50-kHz USVs. These effects of 50-kHz USVs on both dopamine signaling and pro-social behavior were most pronounced in response to the first playback, but then declined rapidly with subsequent presentations, indicating a close relationship between the two measures. The finding that phasic dopamine release in NAcc encodes pro-social 50-kHz but not alarming 22-kHz USVs, further supports the notion that the two call-types are processed by distinct brain areas, involved in regulating approach and avoidance, respectively. Importantly, stimulating dopamine neurotransmission by microinfusion of amphetamine into the NAcc elicits 50-kHz but not 22-kHz USVs (Thompson et al., 2006). Therefore, the NAcc may serve as the functional link

between detection and production of 50-kHz USVs, which is particularly relevant in social reciprocal communicatory signals.

Abstract: Nucleus accumbens dopamine (DA) is a critical component of the brain circuitry regulating behavioral activation and effort-related processes. Interference with accumbens DA alters response allocation in cost/benefit choice procedures that offer animals a choice between high reward/high effort vs. low reward/low effort options. Several behavioral tests have been developed to assess effort-based choice behavior in rats, including maze procedures and operant tasks. Accumbens DA depletions or injection of DA D1 or D2 family antagonists produce a shift in the behavior, decreasing selection of the high reward/high effort option and increasing choice of the low reward/low effort option. Procedures involving effort-related choice behavior could be useful as animal models of psychiatric symptoms such as psychomotor retardation, anergia, and fatigue, which are seen in patients with depression, parkinsonism, and other disorders. For that reason, the current studies investigated the effects of the monoamine depleting agents reserpine (RES) and tetrabenazine (TBZ) on effort-related choice behavior in rats. RES is an irreversible

inhibitor of the vesicular monoamine transporters 1 and 2 (VMAT-1,2), while tetrabenazine is a reversible inhibitor of VMAT-2. RES and TBZ produce depressive side effects in some patients, including motivational symptoms such as psychomotor slowing, anergia, and fatigue. Rats were tested on a concurrent fixed ratio 5 lever pressing/chow feeding choice procedure. With this task, rats can lever press for a more preferred food (high carbohydrate pellets) or consume a less preferred but freely available laboratory chow. Administration of RES and TBZ both decreased lever pressing, but substantially increased chow intake. However, with repeated administration, RES produced severe motor impairments that led to a general disruption of all behavior, and also induced catalepsy. In contrast, TBZ (0.5-1.0 mg/kg) produced consistent effects on choice behavior over several weeks of injections. TBZ also affected effort-related choice in rats tested on a progressive ratio/chow feeding choice procedure, and a task in which rats could choose between lever pressing for a higher concentration of sucrose vs. consumption of a less preferred concentration. Taken together, these results demonstrate that RES is a more difficult drug to work with than TBZ. TBZ injections altered effort-related choice behavior, biasing animals towards low effort alternatives in a consistent and reproducible manner, across multiple tasks. The present research may contribute to the development of novel treatments for effort-related motivational symptoms in humans.

Title: Impact of dopamine D2 receptor antagonism on the activational effects produced by conditioned stimuli and on the preference for primary reinforcers based on their effort requirements.

Authors: *M. CORREA[1], M. PARDO[1], L. LOPEZ-CRUZ[1], T. DOÑATE[1], M. CARBÓ-GAS[1], L. MONFERRER[2], J. D. SALAMONE[3]

Abstract: Mesolimbic dopamine (DA) is a critical component of the brain circuitry regulating behavioral activation and effort-related processes. In the present experiments, the DA D2 receptor antagonist haloperidol was used to study DAergic involvement in the activational and directional components of motivated behaviors in Swiss male mice. Haloperidol (0.1 and 0.2 mg/kg) decreases spontaneous locomotion in an open field (OF) and a running wheel (RW). Presentation of an olfactory conditioned stimulus (CS+) associated with a sucrose solution was able to enhance motor activity in both paradigms. Haloperidol (0.1 mg/kg) did not suppress free intake of sucrose, or sucrose preference relative to water, but did block the activational effects of the CS+ at a dose (0.05 mg/kg) that did not affect spontaneous locomotion. In another experiment, a T-maze task was developed for the assessment of preference for two different types of rewards: physical activity (i.e., running in a RW) in one arm and sucrose access in the other. Under normal conditions sucrose consumption was less preferred. Haloperidol (0.1 mg/kg) produced a shift in arm preference, reducing time spent on the RW, but increasing selection of sucrose. Pre-exposing animals to both reinforcers did not produce this shift. Thus, D2 antagonism reduced the invigorating properties of primary and conditioned reinforcers, with no effect on free access to reinforcers that could be obtained with low effort. In summary, the present results implicate DA D2 receptors in the regulation of behavioral activation and effort-related functions. This research allows for a better understanding of psychiatric symptoms such as psychomotor slowing, fatigue or anergia that can be observed in pathologies like depression. Moreover, it demonstrates that DA systems regulate preference for engaging in physical activities relative to other reinforcing conditions.

Title: Dopaminergic modulation of decision-making in older age

Authors: *R. CHOWDHURY[1,2], M. GUITART-MASIP[2], P. DAYAN[3], E. DUZEL[1,4], R. J. DOLAN[2]
[1]Inst. of Cognitive Neurosci., London, United Kingdom; [2]Wellcome Trust Ctr. for Neuroimaging, London, United Kingdom; [3]The Gatsby Computat. Neurosci. Unit, London, United Kingdom; [4]Otto-von-Guericke-University Magdeburg, Magdeburg, Germany

Abstract: Background: Reinforcement learning is impaired in older age. This may be related to a decline of dopamine neurons which occurs as part of normal aging. Abnormal signalling of reward anticipation and risk-taking in the ventral striatum has been reported in older adults. However the basis of prediction error signalling in older adults has yet to be elucidated.
Objective: To study the effects of pharmacological manipulation with the dopamine precursor levodopa (L-DOPA) on reward-based decision-making and prediction errors in healthy older adults.
Methods: This was a double-blind placebo controlled within-subject study. 32 healthy older adults performed a functional MRI 'two-arm bandit' task, on and off L-DOPA. Participants were required to choose between two stimuli, whereby the outcome was binary (win or no win). The probability of obtaining a reward for each stimulus were independent of each other and varied on a trial-to-trial basis according to a Gaussian random walk distribution. We used a standard reinforcement learning model to fit participants' behaviour, generating a learning rate (α) on placebo and on L-DOPA. We also modelled a choice perseveration parameter. The actual reward (R) and expected value (Qc) were used as parametric modulators of the outcome in the fMRI analysis. Thus the prediction error here represented the difference between the received reward and the expected reward given the choice on that trial.
Results: The percentage of times the optimal stimulus was chosen was similar on placebo and L-DOPA. The learning rate was significantly higher on L-DOPA than placebo, whereas choice perseveration was unaffected. Using a functional ROI approach we defined voxels in the ventral striatum that responded more to the rewards than to the Qc. However, this signal was only fully compatible with a prediction error signal (positive correlation with R and negative correlation with Qc) when participants received L-DOPA.
Conclusions: We show that dopamine increases the learning rate and boosted the prediction error signalling in the ventral striatum in healthy older adults performing a probabilistic reward-based learning task. Importantly, the pattern of prediction errors in the ventral striatum which has often been described in younger adults was only observed in our cohort of older adults following L-DOPA. These results suggest that older adults have abnormal neural representations of expected value which can be normalised by enhancing dopamine.

Title: Simultaneous *in vivo* imaging of changes in volume transmission of dopamine and noradrenaline in mouse cortex during learning

Authors: *A. MULLER[1], V. JOSEPH[4,2], N. TAYLOR[4], P. SLESINGER[4,5,2], D. KLEINFELD[1,2,3]
[1]Physics Dept., [2]Neurosciences graduate program, [3]Neurobio. Dept., Univ. of California San Diego, San Diego, CA; [4]Peptide Biol. Labs., The Salk Inst. for Biol. Studies, La Jolla, CA; [5]Mount Sinai Sch. of Med., New York, NY

Abstract: Volume transmission plays a fundamental role in neuromodulation in the normal and diseased brain. We developed implantable cell–based neurotransmitter fluorescent engineered reporters (CNiFERs) to study the volume conduction of neurotransmitter released in vivo. CNiFERs have a higher spatial resolution (100 µm) and a faster temporal resolution (~ 2 s) than microdialysis and differentiate among monoamines, unlike voltammetry. The first CNiFER was created to detect acetylcholine (ACh). We engineering HEK293 cells to express the M1 muscarinic G protein-coupled receptor (GPCR) and a FRET-based Ca2+ sensor. We have now constructed a new generation of CNiFERs, including a noradrenaline (NA) CNiFER using the Gq coupled alpha-1a adrenergic receptor and a dopamine (DA) CNiFER using the Gi/o coupled D2 type dopaminergic receptor.
The alpha1a-CNiFER exhibited nanoMolar sensitivity for NA (EC50 ~ 7 nM), with no significant cross reactivity at physiological concentrations of other neurotransmitters. In vivo

two-photon microscopy was used to assay alpha1a-CNiFERs chronically implanted in mouse frontal cortex. Alpha1a-CNiFERs responded robustly with an ~30 % increase in FRET to electrical stimulation of the locus coeruleus. The FRET response was blocked with the alpha1a receptor antagonist WB4101 (2 mg/kg, IP).
The D2-CNiFER exhibited nanoMolar sensitivity for DA (EC50 ~ 3 nM), also with no significant cross reactivity. In an ex vivo preparation that included the ventral tegmental area (VTA), D2-CNiFERs measured DA release induced by high [K+]. In vivo two-photon imaging with implanted D2-CNiFERS revealed a robust FRET change following electrical stimulation of the VTA. Response of the D2-CNiFERs to VTA stimulation was substantially enhanced by systemic injection of cocaine (15 mg/kg, IP) or methamphetamine (2 mg/kg, IP) and blocked by the D2 receptor antagonist eticlopride (0.1mg/kg, IP).
We are currently using the alpha1a- and D2-CNiFERs to simultaneously resolve the spatial and temporal dynamics of monoamine concentrations in cortex during Pavlovian and operant conditioning. With a tone-based paradigm using sugar water as a reward, the release of DA across multiple trials is observed to shift from the time of the reward toward that of the conditioning stimulus. In contrast, the release of NA appears to be timed to the reward.

Title: Neurofeedback-mediated self-regulation of substantia nigra

Authors: *J. S. SULZER[1], R. SITARAM[2], M. BLEFARI[1], S. KOLLIAS[3], N. BIRBAUMER[4], K. STEPHAN[1], A. LUFT[3], R. GASSERT[1]

Abstract: The dopaminergic system has been shown to play a role in fine motor skills, behavioral choice and reinforcement learning. It has also been shown to be highly involved in neurological diseases such as Parkinson's disease. Current approaches that aim at enhancing dopaminergic neurotransmission include different pharmacological agents. The goal of this study is to examine whether one can gain control of own dopamine production through guided mental imagery in the form of neurofeedback. To this extent, we used real-time functional magnetic resonance imaging (rtfMRI) neurofeedback, supplying online visual feedback of the blood oxygenation level dependent (BOLD) signal of substantia nigra and ventral tegmental area complex (SN/VTA). We examined two groups of subjects receiving contingent neurofeedback, one group receiving visual feedback positively proportional to SN/VTA BOLD signal (up-regulation), the other group receiving negatively proportional feedback (down-regulation). We recorded skin conductance response (SCR) during neurofeedback as a measure of attention to the task. We found that after one session, both groups significantly activated SN/VTA. However, the groups differed in the correlations between SN/VTA BOLD signal and SCR. Specifically, the SN/VTA activity was positively correlated to SCR in the up-regulation group, whereas the down-regulation group had a negative trend, significantly smaller than the up-regulation group . This result suggests that the ability to self-regulate SN/VTA BOLD signal is modulated by attention to the task. In addition to significant increases in SN/VTA in the up-regulation group, whole brain random effects analysis and psychophysiological interaction show a strong role of nucleus accumbens and hippocampus, indicating the possible role of the mesolimbic dopaminergic pathway. This is the first reporting of voluntary control of the midbrain dopamine pathways and represents a first step towards endogenous upregulation of dopaminergic transmission.

Title: Acquisition and expression of catalepsy sensitization to haloperidol is conditional on the interaction between the drug and test environment

Authors: *T. J. BANASIKOWSKI[1], R. J. BENINGER[2]
[1]Ctr. Neurosci Studies, [2]Psychology, Psychiatry and Ctr. for Neurosci., Queen's Univ., Kingston, ON, Canada

Abstract: Dopamine (DA) plays a critical role in our ability to move and in some forms of learning. DA drugs used to treat Parkinson's disease and schizophrenia produce progressively greater effects on behavior with repeated exposures (i.e., behavioral sensitization). Low doses of the DA D2-receptor preferring antagonist haloperidol (0.25 mg/kg, i.p.), repeatedly injected in a particular environment, produce day-to-day increases in catalepsy, quantified by time spent on a horizontal bar without active movement. In experiment 1, we observed that expression of catalepsy sensitization is environment-specific, as it is not observed when testing is performed in different environments despite usual haloperidol treatment. Furthermore, places associated with repeated haloperidol injections and catalepsy tests also elicit catalepsy, now conditioned. This was observed when saline was substituted for haloperidol and rats were tested in their regular, but not in a novel test environment. Following repeated saline-environment pairings, conditioned catalepsy was extinguished. Post-extinction challenge with haloperidol produced a small catalepsy response that was now independent of the test environment, suggesting that the haloperidol drug cue alone can elicit conditioned catalepsy. In experiment 2, we show that expression of the sensitization response is dependent on a drug-environment interaction, as animals with a previous history of drug treatment in a different environment failed to exhibit significant catalepsy when given haloperidol in the test environment. In experiment 3, we show for the first time that habituation to the test environment prior to commencing haloperidol treatment significantly enhanced the rate of catalepsy sensitization. This was not observed when habituation was performed in a different environment. Thus, acquisition and expression of catalepsy sensitization to haloperidol is conditional on the interaction between the drug and test environment. Moreover, it appears that the sensitization effect is due to a progressive loss of exploratory behaviors as a consequence of decreased engagement with environmental stimuli, which eventually manifests as catalepsy. Results suggest that the therapeutic effects of antipsychotic drugs depend on the environment associated with their use.

Title: Conditioned inhibition and the learning of negative values

Authors: *J. MOLLICK[1], R. O'REILLY[1], T. WAGER[1], G. FRANK[2]
[1]Dept. of Psychology and Neuroscience, Univ. of Colorado Boulder, Boulder, CO; [2]Univ. of Colorado Denver, Anschutz Med. Campus, Denver, CO

Abstract:

While the dopamine system in reward prediction is often modeled with the temporal-differences algorithm, we use a more biologically plausible model that considers the distinct computations of different brain areas. In our model, the central nucleus of the amygdala learns an association of a stimulus with reward, the ventral striatum inhibits the dopamine burst for a predicted reward, and the lateral habenula learns about negative valence rewards and the omission of positive rewards, and can inhibit the VTA to cause a dopamine dip for an omitted or negative valence reward.

To test our model's prediction that the learned value signal in the amygdala can be dissociated from the mechanism that inhibits dopamine firing at the time of reward, we ran a conditioned inhibition task, where subjects are conditioned on the pairing of a stimulus (A) with orange juice, and the pairing of a control stimulus with a neutral solution.

This is followed by four blocks of conditioned inhibition, which include the conditioned stimulus (A) and control from the earlier block. In these blocks, we also introduce a conditioned inhibitor (X) that predicts receipt of a neutral solution when paired with the reward-predictive stimulus. The inhibitor is shown alone and paired with the conditioned stimulus. These blocks also include the non-rewarded control, and a non-rewarded pairing of the control with another stimulus.

A preliminary analysis (n=12) found that the average activity for the conditioned stimulus was significantly greater than zero in the central nucleus of the amygdala. There was also significantly more central amygdala activity for the inhibitor (viewed alone) than to the control stimulus, which could be due to the salience of the inhibitor.

In the ventral tegmental area, we saw a significant decrease in activity for the CS-Inhibitor pair compared to the Inhibitor alone, which supports the idea that dopamine may also code for

salience. In the habenula region, we saw activity for the CS-Inhibitor pair compared to the control stimulus, indicating that it may be involved in the cancellation of an expected reward.

Title: Development of rodent models of the motivational symptoms of depression: The catecholamine depleting agent tetrabenazine affects effort-related decision making in the T-maze barrier choice task.

Authors: *S. E. YOHN[1], E. J. NUNES[1], P. A. RANDALL[1], Y. BAQI[2], C. E. MÜLLER[2], M. CORREA[1,3], J. D. SALAMONE[1]
[1]Psychology, Univ. of Connecticut, Storrs, CT; [2]Univ. Bonn, Bonn, Germany; [3]Univ. of Jaume I, Castello, Spain

Abstract: Mesolimbic dopamine (DA), particularly within the nucleus accumbens, has been shown to be a critical component of brain circuitry regulating behavioral activation and effort-related processes. Previous studies have shown that interference with accumbens DA alters response allocation in choice procedures that involve evaluations of reinforcement value and response costs. Several behavioral tests have been developed to assess effort-based choice behavior in rats, including maze procedures and operant tasks. The T-maze choice procedure developed by our laboratory is a frequently used task, in which the two arms of the maze contain different reinforcement densities (four vs. two or four vs. zero) and under some conditions a 44 cm barrier is placed in the high reinforcement density arm to create an effort-related obstacle. Under baseline or control conditions, rats will climb the barrier to receive the high-density reinforcement, while making relatively few selections of the low reward/low cost arm. However, accumbens DA depletions, or administration of DA D1 or D2 family antagonists (e.g. ecopipam or haloperidol), produce a shift in this behavior, thereby increasing low-density arm selection and decreasing selection of the high cost/high reward arm. It has been suggested that these drug-induced shifts in effort-based choice that are seen in animals could be analogous to symptoms

such as psychomotor retardation, anergia, and fatigue, which can be observed in individuals with depression, parkinsonism, and other disorders. For that reason, the current studies investigated the effects of the catecholamine depleting agent tetrabenazine on effort-related choice behavior using the T-maze procedure. Tetrabenazine inhibits the vesicular monoamine transporter 2 (VMAT-2) and is used to treat Huntington's disease. Tetrabenazine has been shown to produce depressive side effects in some patients, including motivational symptoms such as psychomotor slowing, anergia and fatigue. In rats tested on the T-maze choice procedure, administration of tetrabenazine in a dose range of 0.25-0.75 mg/kg IP decreased high-density arm selection but increased low-density arm selection. Initial evidence indicates that these effects of tetrabenazine on effort-related choice behavior can be reversed by co-administration of the adenosine A2A antagonist MSX-3. Collectively, these results demonstrate that administration of low doses of tetrabenazine can alter effort-related choice behavior, biasing animals towards low effort alternatives. The present research may contribute to the development of novel treatments for effort-related motivational symptoms in humans.

Title: Galanin GalR1 but not GalR2 receptors influence mesolimbic dopamine-mediated behavioral energizing.

Authors: M. E. ANDERSON[1], J. RUNESSON[2], I. SAAR[3], Ü. LANGEL[2], *J. K. ROBINSON[1]
[1]SUNY Stony Book, Stony Brook, NY; [2]Stockholm Univ., Stockholm, Sweden; [3]Tartu Univ., Tartu, Estonia

Abstract: Galanin is a 29-amino acid long neuropeptide that has been implicated in many physiological and behavioral functions. Previous research has shown that i.c.v. administration of galanin strongly stimulates food intake in sated rats when food is freely available, but fails to stimulate this consumption when an operant response requirement is present. Mesolimbic dopamine (DA) pathways are also thought to play a role in this appetitive motivation to obtain a reward. Notably, it has been shown previously that fixed ratio schedules involving very little work are largely unaffected by DA depletions, while schedules that involve high work requirements are greatly impaired by these same depletions. Based upon this clear dissociation, the present study had several aims. First, using fixed ratio (FR) schedules, we sought to test the theory that galanin interacts with mesolimbic dopamine by administering galanin i.c.v. to rats working fixed ratio schedules requiring either a low work condition (FR1) or a high work condition (FR >1) to obtain a 0.2% saccharine reward. Consistent with actions of galanin only when dopamine would be released by the high work requirement, the rate of reinforcer receipt decreased for only the FR>1 group as compared to saline controls. Furthermore, injections of GalR1 receptor agonist M617 led to a similar selective decrease in the number of reinforcers received in the galanin-injected rats of the FR>1 group, but a similar decrease was not seen after injections of GalR2 receptor agonist M1153. Taken together, these results show a clear galanin-dopamine interaction at times of appetitive behavior, mediated by the GalR1 receptor.

Title: Winners, losers, workers and slackers: Individual differences in exertion of effort on a progressive ratio/ chow feeding choice task are related to differences in DARPP-32 (Thr34) expression in nucleus accumbens core

Authors: *M. PARDO[1,2], P. A. RANDALL[2], E. J. NUNES[2], L. LÓPEZ-CRUZ[1], M. CORREA[1,2], J. D. SALAMONE[2]

[1]Univ. Jaume I, Castelló, Spain; [2]Dept. of Psychology, Univ. of Connecticut, Storrs Mansfield, CT

Abstract: Several behavioral tests have been developed to assess effort-based choice behavior in rats, including a T-maze barrier choice task and various operant procedures. Recently, a progressive ratio (PROG)/chow feeding concurrent choice procedure was developed, in which rats can press on a PROG schedule reinforced by presentation of preferred high carbohydrate operant pellets, or alternatively, can approach and consume a less preferred chow that is available in the chamber. The rat passes through each ratio level by completing 15 ratios, after which the ratio requirement is incremented by one additional ratio (e.g. FR1 15 times, FR2 15 times, etc.). The PROG schedule stays active as long as the rats receive a reinforcer every 2 min. Typically, rats lever press until the PROG schedule times out, and the animals then consume considerable chow. Thus, the rats eventually reach a point in the session at which the ratio requirement becomes too high, so they switch to chow. Administration of the dopamine (DA) D2 antagonist haloperidol (0.025-0.1 mg/kg IP) significantly reduced number of lever presses, highest ratio achieved, and active lever time. Haloperidol did not reduce chow intake, and if anything there was a tendency to increase chow intake in some rats. Performance on the PROG/chow feeding choice task was highly variable; some rats lever pressed fewer than 100 times and had high levels of chow intake, while others lever pressed more than 1000 times and consumed only small amounts of chow. Moreover, the effects of haloperidol were more marked in rats with higher control levels of lever pressing; analysis of effect sizes showed that the suppressive effect of haloperidol on number of lever presses was greater in high responders (eta2 = 0.236) than low responders (eta2 = 0.157). For these reasons, an additional experiment investigated potential neurochemical differences between high and low responders, using pDARPP-32(Thr34) immunocytochemistry as a marker of signal transduction activity that has been linked to DA receptor activation. To analyze the DARPP-32 expression data, a median split based upon behavioral performance during the final test day was performed. After the behavioral session, rats with high levels of PROG lever pressing showed significantly greater pDARPP-32(Thr34) expression in nucleus accumbens core relative to low responders. There were no differences in accumbens shell and cingulate cortex expression. These results highlight the importance of DA transmission, as well as signal transduction activity in accumbens core neurons, as markers of individual differences in effort-related performance.

Title: Responding for conditioned reinforcement in mice: Effects of strain, operant response type, and methylphenidate

Authors: *C. BROWNE[1], P. J. FLETCHER[2,3]
[1]Univ. of Toronto/Camh, Toronto, ON, Canada; [2]Biopsychology, Ctr. for Addiction and Mental Hlth., Toronto, ON, Canada; [3]Psychology, Univ. of Toronto, Toronto, ON, Canada

Abstract: Environmental stimuli associated with primary rewards such as food or drugs of abuse acquire incentive motivational significance through associative learning and can function as conditioned reinforcers (CR). In drug addiction, these types of stimuli may induce cravings and lead to relapse. Attribution of salience to reward-associated stimuli may be mediated partly through a dopamine (DA) dependent mechanism. Although much has been learned about incentive motivation from studies of conditioned reinforcement in rats, few studies have examined this phenomenon in mice. This is surprising due to the potential for using transgenic mice to explore brain mechanisms in incentive motivation. These experiments assessed 1) whether mice would learn a stimulus-reward association, 2) whether that stimulus would function as a CR, 3) the temporal stability of responding for this CR, and 4) whether responding would be altered by enhancing DA function. We also explored factors related to strain differences and nature of the operant response.
Water-restricted mice (C57Bl/6 or CD1) received 30 pairings of a conditioned stimulus (CS; light+noise) with 0.01 ml 0.2% saccharin in each of 14 daily 40 min sessions. Subsequently, mice were allowed access to 2 response levers or 2 nose-poke ports. Responding on one lever or port delivered the CS (now a CR); responses on the other lever or port had no effect. Mice were tested four times following an i.p. injection of saline or the DA reuptake blocker methylphenidate (MPH; 2.5, 3.5, 5 mg/kg).
All mice learned to approach the saccharin magazine when the CS was presented. Subsequently, mice learned to selectively respond on the lever or port delivering the CR. Within each strain, responding for the CR on the levers versus the ports was roughly equivalent, while CD1 mice showed more responding than C57 mice overall. MPH increased lever responding for the CR but only in the CD1 strain.
The results show that mice can learn a simple stimulus-reward relationship and respond for that stimulus when it functions as a CR. Responding for CR may be more pronounced in the CD1 strain and is enhanced by increasing DA function in this strain. These findings potentially set the stage for using transgenic mice to explore brain mechanisms involved in incentive learning.

Title: The effects of Salvinorin A on conditioned place preference formation, locomotor behavior, and immediate-early gene expression in midbrain dopaminergic neurons

Authors: W. JENKINS[1], J. SALVATIERRA[2], *K. NORTHCUTT[2]
[1]Psychology Dept., [2]Biol. Dept., Mercer Univ., Macon, GA

Abstract: Salvinorin A (SA), the primary psychoactive agent in the increasingly popular recreational drug salvia, has been classified as a selective kappa opioid agonist. However, recent research suggests that SA may directly interact with the dopamine (DA) system because some of its effects are blocked by a DA antagonist, but not by a kappa opioid antagonist. Given DA's role in mediating the reinforcing properties of various drugs of abuse, SA may have abuse potential. Currently, there is very little published research investigating this possibility, and the research that does exist is somewhat equivocal with some doses resulting in conditioned place preference (CPP) for SA -paired chambers and others showing conditioned place aversions. In addition, the ability of SA to induce locomotor sensitization, another marker of abuse potential, is unknown. The current study investigated whether several different doses (0.1, 10, or 50 μg/kg) of SA would support the development of CPP in adult male rats, and whether repeated SA administration at these same doses would affect psychomotor activation. Finally, because little is known about the dopaminergic networks that SA acts on in the brain, we examined immediate-early gene expression in midbrain DAergic neurons one hour after SA administration using double-label immunohistochemical procedures for tyrosine hydroxylase (TH), the rate-limiting enzyme in dopamine synthesis, and the immediate-early gene product Fos. We observed a CPP only in those animals receiving 10 μg/kg SA, and these same animals had greater locomotor activity after repeated administration of this dose of SA. In addition, there were significantly more TH/Fos double-labeled cells in the substantia nigra of animals receiving an injection of 10 μg/kg SA compared to all other doses of SA and the control animals, but we did not find differences among treatment groups in the ventral tegmental area. The other doses we tested did not support CPP, and they did not significantly affect locomotor activity or the number of

double-labeled cells in the brain areas examined. We conclude that SA, at least at some doses, may indeed represent a potential drug of abuse that markedly affects the DA system and the motor responses that it generates.

Title: Does adolescent ethanol exposure change the response to acute ethanol in adulthood? Preliminary results on social behavior, dopamine release and gene expression

Authors: *D. L. ROBINSON[1], W. F. MATHES[2], D. L. ZITZMAN[1], W. H. CHAPMAN[1], L. P. SPEAR[3]
[1]Bowles Ctr. for Alcohol Studies, [2]Dept. Psychiatry, Univ. of North Carolina, Chapel Hill, NC; [3]Dept. Psychology, Ctr. Develop. & Behavioral Neurosci., Binghamton Univ., Binghamton, NY

Abstract: Adolescence marks a dynamic period within the mesolimbic dopamine system. During this developmental stage, dopamine release and receptor expression peak, followed by a gradual decline into adulthood. In addition, prefrontal cortical projections to subcortical targets are undergoing myelination and pruning. The brain changes occurring during adolescence are thought to underlie the enhanced sensitivity to reinforcing stimuli, such as social reward and addictive drugs that is observed in adolescent humans and animal models. Given this marked remodeling of mesocorticolimbic dopamine systems and the sensitivity of dopamine to social stimuli, we investigated the functional impact of adolescent intermittent ethanol exposure (AIE) on aspects of dopamine transmission in adulthood. We exposed male rats to i.g. injections of vehicle (“super-sac”: 0.125% saccharin and 3% sucrose) or ethanol using an AIE schedule of 2.5g/kg i.g. (25% ethanol v/v in super-sac) every other day from P25 - P45. This dosing produced ~80mg% in tail blood samples collected 30 min after administration. Rats were tested in early adulthood at P80±1 day for dopamine release after saline or ethanol challenge (0.5 or 1

g/kg ethanol, i.p.). Dopamine release in the ventral striatum was measured with fast scan cyclic voltammetry at baseline, after challenge injection, and during three brief periods of interaction with another rat. We confirmed that 1 g/kg ethanol administration and brief social interactions both increase the frequency of dopamine transients, consistent with our previous reports. Moreover, analysis of behavior during social interaction shows that AIE treatment reduces social contacts in the first interaction, while ethanol yielded a biphasic effect, with 0.5 g/kg facilitating and 1 g/kg inhibiting social contacts in the third interaction. A concurrent experiment evaluated gene expression in animals having undergone the same treatments. Gene expression in the prefrontal cortex and striatum was assessed with Affymetrix microarrays. Preliminary analysis found that 68 genes in the PFC and 191 genes in the striatum were significantly differentially expressed in animals exposed to AIE and/or acute ethanol challenge, and several of these genes have a direct effect on DA signaling, receptor binding, and DA neuronal development.

Title: Nucleus accumbens dopamine transmission during decisions involving trade-offs between reward value and effort requirement

Authors: *N. G. HOLLON[1,2], M. M. ARNOLD[1], J. O. GAN[4], M. E. WALTON[5], P. E. M. PHILLIPS[1,2,3]
[1]Psychiatry & Behavioral Sci., [2]Grad. Program in Neurobio. & Behavior, [3]Pharmacol., Univ. of Washington, Seattle, WA; [4]Neurol. & Neurosci., Weill Cornell Med. Col., New York, NY; [5]Exptl. Psychology, Oxford Univ., Oxford, United Kingdom

Abstract: As a corollary of signaling errors in reward prediction, the magnitude of phasic dopamine transmission to the unexpected presentation of a reward-predictive cue reflects the

expected value associated with that cue. We recently demonstrated that dopamine release in the nucleus accumbens to the presentation of single cues encodes their expected reward value but not response cost involving different effort requirements. Here we use this insight to investigate the unresolved question of what dopamine transmission signals during choices between options of different value. In particular, there remains a discrepancy in the literature regarding whether dopamine encodes the value of the subsequently chosen option or the greatest value available regardless of what the animal ultimately chooses. Unlike these previous studies, however, our current design does not depend on analysis of anomalous choices for an option with low overall utility.
We used fast-scan cyclic voltammetry to record rapid changes in dopamine concentration in the nucleus accumbens of rats performing a decision-making task in which two levers were associated with different reward sizes and effort requirements. Each session included single-option "Forced" trials intermixed with two-option "Choice" trials. In one session type, one lever earned a small reward for a low response cost, and the other lever earned a large reward for a moderate cost. Rats significantly preferred the large reward / moderate cost option, and cue-evoked dopamine release showed the expected coding of reward value on Forced trials, with greater release for the large than the small reward option. In other sessions, rats instead preferred the small reward / low cost option over a large reward / high cost option. We observed greater sustained dopamine concentration following the large reward / high cost option but no difference in peak dopamine release to the two options. Cue-evoked dopamine release during Choice trials was similar to that in the corresponding Forced trials in both session types. These results support the notion that accumbens dopamine transmission signals the value of the subsequently chosen option. The magnitude of cue-evoked phasic dopamine, however, reflects an interaction between expected reward value and net utility (as revealed by behavioral preference) but not a simple encoding of either in isolation.

Title: Hyperactivity is reduced by environmental enrichment during growing period in an ADHD model rat accompanied with enhanced CART expression in medial prefrontal cortex

Authors: *Y. SHIMIZU, R. NISHIGAKI, Y. WATANABE, Y. UEDA, S. MISUMI, T. MASUDA, H. HIDA
Neurophysiol. & Brain Sci., Nagoya City Univ. Grad. Sch. of Med. Sci., Nagoya, Japan

Abstract: Attention deficit hyperactivity disorder (ADHD) is characterized by hyperactivity, impulsivity and inattention. Spontaneously hypertensive rat (SHR) is often used as a behavioral animal model of ADHD. Dysfunction of mesocorticolimbic dopamine (DA) system such in nucleus accumbence (NAc), amygdala (Amy) and medial prefrontal cortex (mPFC) is related to ADHD: deficits of DA transporter and DA type 4 receptor (D4R) are known as genetic factor while environmental condition are important in brain DA system as well. To investigate the effect of environmental enrichment (EE) during the growing period on ADHD-like behavior in SHR, SHR were allowed to grow in EE, standard environment (SE) or isolated environment (IE) from weaning (P25) to adulthood for 5 weeks, followed by behavioral assessment in open-field test and cylinder test. In open-field test, the decrease in hyperactive locomotion was shown in rats reared in EE, and the velocity was slow in EE compared to SE or IE. In cylinder test, the rats grown in EE showed the significant decrease in anxiety behavior (rearing and locomotion) as compared to those in SE or IE. Therefore, we investigated gene expression of D4R and cocaine and amphetamine regulated transcript (CART) in mPFC, NAc and amygdala. There were no differences of D4R expression in those areas. Significant enhancement of CART mRNA was shown in mPFC of EE group. Immunostaining revealed that CART did not colocalized with parvalbumin-positive GABAergic neurons in mPFC. Data suggest that EE during the growing period improves hyperactivity with change of CART expression in mPFC.

Title: CS-evoked ERK activation in the nucleus accumbens during Pavlovian-instrumental transfer is mediated by D1 dopamine receptors

Authors: *M. L. REMUS[1,2], C.-A. DOMJAN-YUHAS[3], E. THIELS[4,2,3]
[1]Biol. Sci., Carnegie Mellon Univ., Pittsburgh, PA; [2]Ctr. for the Neural Basis of Cognition, Pittsburgh, PA; [3]Ctr. for Neurosci., Pittsburgh, PA; [4]Dept. of Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: When a neutral stimulus is repeatedly paired with reward, it becomes a cue predictive of the reward. Studies have shown that exposure to such a conditioned stimulus (CS) potentiates behavior aimed at obtaining the reward, as occurs during Pavlovian-instrumental transfer (PIT). We showed that an appetitive CS causes activation of extracellular signal-regulated kinase (ERK) in both the core and shell of the nucleus accumbens (NAc), and that NAc ERK activation is crucial for PIT (Shiflett et al., 2008; Remus & Thiels, submitted). The receptor pharmacology of the CS-evoked ERK activation during PIT is not known. D1 dopamine receptor (D1R) activation is coupled positively to ERK activation in striatal cells (Bertran-Gonzalez et al., 2008). We therefore wanted to determine whether D1R activation plays a role in the CS-evoked increase in active ERK (pERK) in both the core and the shell during PIT. Rats were fitted bilaterally with cannulae aimed between the core and shell of the NAc, and trained with a Pavlovian and an instrumental conditioning paradigm, as described previously. Immediately before the PIT test, the D1R-type antagonist SCH23390 was infused into the NAc on one side and vehicle solution on the other. Unilateral infusion of SCH23390 had no effect on PIT. Comparison of pERK immunoreactive cell counts between the drug- and vehicle-treated NAc revealed that SCH23390 completely blocked the CS-evoked increase in ERK activation in both the core and the shell. Consistent with a requirement of NAc ERK activation for PIT, bilateral infusion of SCH23390, but not of vehicle solution, disrupted PIT, without effect on basal instrumental responding for food reward. Our findings indicate that D1Rs play a critical role in mediating PIT-relevant ERK activation in the NAc, and they suggest D1Rs as a pharmacological target by which NAc ERK and, by extension, PIT can be modulated. We now are determining the NAc cell phenotype in which the D1R-mediated CS-evoked ERK activation occurs using a combination of pharmacological D1R blockade and dual-immunoflurorescence staining for pERK and DARPP32, a protein expressed only by NAc projection neurons, or preprodynorphin (PPD), a protein expressed only by D1R-containing NAc projection neurons. We expect overlap of the pERK signal with DARP32 and PPD staining, and that intra-NAc infusion of SCH23390 will abolish the pERK signal but have no effect on the DARP32 or PPD signal. These data would indicate that CS-evoked ERK activation in the NAc occurs selectively in D1R-containing medium spiny neurons. The results thereby suggest that inputs to and targets of D1R-expressing medium spiny neurons are critical elements of the circuit underlying PIT.

Title: Repeated pre-treatment with amphetamine enhances cue-potentiation of reward seeking and associated ERK activation in multiple structures of the reward system

Authors: *J. C. MAUNA[1,2], E. THIELS[2,3,4]
[1]Neurosci., Univ. Pittsburgh, PITTSBURGH, PA; [2]Ctr. for Neurosci., [3]Neurobio., [4]Ctr. for the Neural Basis of Cognition, Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Stimuli that repeatedly were paired with reward can potentiate behaviors aimed at obtaining the reward. This effect of conditioned stimuli (CS) on reward seeking [Pavlovian-Instrumental Transfer (PIT)] depends on the reward system, most notably the nucleus accumbens (NAc). Exposure to an appetitive CS increases ERK2 activation in the NAc of rats, and blockade of NAc ERK interferes with PIT (Shiflett et al. 2008). Amphetamine (AMPH) treatment after daily Pavlovian conditioning enhances CS-evoked ERK2 activation as well as CS-potentiation of reward seeking in drug-free rats (Mauna et al. SfN 2011). Here, we examined whether the AMPH-induced enhancement of PIT is associated with increased ERK activation in both subregions of the NAc, and whether CS-evoked ERK activation is modulated by AMPH pretreatment in other structures of the reward system. Rats received daily sessions of tone-food (CS-US) pairings and were treated with either AMPH (1 mg/kg, i.p.) or saline (SAL) immediately after each session. Rats then were trained to press a lever for food. Seven days after the last drug treatment, rats underwent PIT testing, and then brains were removed for analysis of ERK activation. Basal NAc ERK activation was determined in control rats that received tone presentations only (no food) during Pavlovian training but otherwise were treated identically to rats that received tone+food (T+F) pairings. The enhancing effect of AMPH pre-treatment on CS-evoked ERK activation, as determined by Western blot, and on CS-potentiated lever pressing, was maintained for at least 7 days after the last drug treatment. The AMPH effect was observed throughout the NAc: pERK(+) cells were more abundant in both the core and the shell of AMPH- compared to SAL-treated T+F rats, while the pERK(+) cell count was equally low in

both control groups. A similar pattern of results was observed in the prefrontal cortex (PFC), in particular in the deeper layers, as well as in the basolateral amygdala (BLA). Interestingly, pERK(+) cells in the dorsolateral striatum (DLS) were more numerous, relative to control rats, only in AMPH- but not SAL-treated T+F rats. Neither training nor drug treatment affected pERK staining in the dorsomedial striatum. Consistent with previous work, our findings implicate the BLA in the mediation of PIT. Additionally, our findings suggest that the PFC also is part of the PIT circuit, and, importantly, that the AMPH effect on PIT entails recruitment of all three key elements of the reward system studied here. Our results suggest that the dorsal striatum does not play a role in PIT, although the DLS may contribute to enhancement of PIT caused by prior exposure to a psychostimulant.

Title: The effects of pramipexole on conditioned responding in “sign-trackers” and “goal-trackers”

Authors: *J. HAIGHT[1], R. KELLEY[1], S. B. FLAGEL[1,2]
[1]Psychiatry, [2]Mol. Behavioral Neurosci. Inst., Univ. of Michigan, Ann Arbor, MI

Abstract: Pramipexole, a dopamine D2/D3 receptor agonist, is a therapeutic drug used to treat the symptoms of various maladies including Parkinson’s Disease, restless-leg syndrome and fibromyalgia. A subset of patients treated with pramipexole have been found to develop impulse control disorders (ICDs), centered around compulsions such as gambling, eating, illicit drug-taking or sexual behavior. Why only certain individuals are predisposed to develop these ICDs is largely unknown. In recent years, a rodent model exploring individual differences in response to a reward-paired stimulus has shed light on the psychological and neurobiological processes that likely contribute to such impulsive behaviors. When trained in a Pavlovian conditioning task, outbred Sprague-Dawley rats will develop a conditioned response that consists primarily of either “sign-tracking” or “goal-tracking” behavior. Sign-trackers (STs) direct their behavior towards the “sign” or conditioned stimulus (CS) associated with reward delivery, while goal-trackers (GTs) approach the location of reward delivery upon CS presentation. Importantly, it has been shown that the CS comes to have motivational value, or incentive salience, for STs, and

that learning of the sign-tracking (but not the goal-tracking) response is dependent on dopamine. Using this model of individual differences in the attribution of incentive salience, we sought to identify distinct traits that might render one susceptible to developing ICDs when administered pramipexole. Outbred Sprague-Dawley rats were trained in a Pavlovian-conditioning task, where presentation of a lever-CS predicted delivery of a food pellet. After seven days of training, animals were classified as STs or GTs based on their conditioned response (CR) to lever presentation. Animals from each group were then treated with either saline or three different doses in descending order (0.32, 0.1 and 0.032 mg/kg, s.c.) of pramipexole immediately prior to the next three conditioning sessions, and changes in the expression of the conditioned responses were assessed. Since higher doses of pramipexole can increase nonspecific responding, this was controlled for and was not a factor within this dose range. Preliminary results indicate that 0.032 and 0.1 mg/kg of pramipexole attenuates CR expression in both STs and GTs, while the higher dose of 0.32 mg/kg decreases expression only in STs. Additional studies and analyses are currently underway to further our understanding of the effects of pramipexole on CR expression in STs and GTs.

Title: The mGlur5 antagonist MTEP impairs the acquisition of the extinction of alcohol-seeking

Authors: K. E. HUTTON-BEDBROOK, *G. P. MCNALLY
Univ. New South Wales, Sydney, Australia

Abstract: Extinction learning in several conditioning preparations depends on glutamatergic neurotransmission, but the role of glutamate in extinction of drug seeking, and the specific receptors involved, remain poorly understood. Recent evidence has identified a role for metabotropic glutamate receptors in drug seeking behaviours. We investigated the role of mGluR5 and NMDA receptors in the acquisition and expression of the extinction of alcohol-seeking as well the neuroanatomical locus for this effect. Male Long-Evans were trained in 1 hr sessions across 7 days to respond for alcoholic beer. Following this, animals underwent extinction training during which responding was no longer reinforced. In Experiment 1, injection

of the mGluR5 antagonist MTEP (1 mg/kg) impaired the acquisition but not expression of extinction. In contrast, in Experiment 2 injection of the NMDA receptor antagonist ifenprodil (3 mg/kg) did not impair extinction learning. In Experiment 3 the impairment of extinction learning by MTEP was shown to be dose-dependent. Finally, Experiment 4 studied the role of basolateral amygdala (BLA) mGluR5 receptors in extinction learning by microinjecting MTEP into the BLA prior to extinction training. Taken together, these experiments identify a role for mGluR5 receptors in extinction learning during drug self-administration.

Title: alpha-CaMKII autophosphorylation regulates morphology of post-synaptic densities in the hippocampus and mice behaviour after alcohol treatment

Authors: *K. RADWANSKA, M. LIPINSKI, M. SZYMANSKI, K. ŁUKASIEWICZ
The Nencki Inst., Warsaw, Poland

Abstract: Ca2+/calmodulin-dependent kinase II (alpha-CaMKII) is a major protein of glutamatergic synapses in the forebrain. Its role in learning and memory processes is very well documented. Its function in addiction-related processes, is however largely unknown. Here we show that alpha-CaMKII autophosphorylation deficient mutants (CaMKII-T286A) have altered behavioural response to alcohol. The T286A mutants do not show increased locomotor activity or decreased anxiety in open field and elevated zero-maze, as observed in wild-type mice. These behaviours are also not sensitised in the mutants after chronic alcohol treatment, as it is observed in the wild-type animals. Furthermore, we show that alcohol treatment (2.5 g/kg) decreases an average size of immunopositive puncta for a marker of post-synaptic densities, PSD95, in the CA1 field of the hippocampus of the wild-type mice. This phenomenon does not occur in alcohol-treated T286A mutants. Thus our data show that alpha-CaMKII autophosphorylation is involved both in the regulation of psychostimulant effects of alcohol, and alcohol-induced changes in the morphology of post-synaptic densities in the hippocampus. These observations

suggest that psychostimulant effects of alcohol involve remodelling of post-synaptic densities in the hippocampus and this process is regulated by CaMKII autophosphorylation.

Title: Effect of the Toll-like receptor 4 antagonist (+)- naltrexone on incubation of heroin craving

Authors: S. KAMBHAMPATI[1], H. EICHENBAUM[1], C. L. PICKENS[1], J. M. BOSSERT[1], K. RICE[2], L. R. WATKINS[3], Y. SHAHAM[1], *F. R. THEBERGE[1]
[1]NIH/NIDA BRC, Baltimore, MD; [2]Natl. Inst. on Alcohol Abuse and Alcoholism, Natl. Inst. of Hlth., Rockeville, MD; [3]Dept. Psychology & Neurosci., Univ. Colorado At Boulder, Boulder, CO

Abstract: Recent evidence implicates the glial toll-like receptor 4 (TLR4) in morphine analgesia, tolerance, and reward, as assessed in the conditioned place preference procedure. Here we used the selective TLR4 antagonist (+)-naltrexone (a μ-opioid receptor inactive isomer) to determine the role of this receptor in the time-dependent increases in cue-induced heroin seeking during forced abstinence (incubation of heroin craving). We trained rats for 9 h/day to self-administer heroin (0.1 mg/kg/infusion) for 9 days; lever presses were paired with a 5-sec tone-light cue. We then assessed cue-induced heroin seeking in 30-min extinction sessions on abstinence day 1; immediately after testing, we implanted the rats with Alzet minipumps delivering (+)-naltrexone (0, 15.0, or 30.0 mg/kg/day, s.c) for 14 days. We then tested the rats for incubated cue-induced heroin seeking in 3-h extinction tests on abstinence day 13. We found that both doses of (+)-naltrexone decreased cue-induced heroin seeking on abstinence day 13. Results suggest a critical role of the glial TLR4 in the development of incubation of heroin craving. We currently study the effect of acute injections of (+)-naltrexone on incubation of heroin craving.

Title: Dietary tyrosine/phenylalanine depletion blunts human mesolimbic recruitment by prospective rewards

Authors: *J. M. BJORK[1], S. J. GRANT[2], G. CHEN[3], D. W. HOMMER[4]
[1]DCNBR-Clin Neurosci Br., NIH/NIDA, BETHESDA, MD; [2]DCNBR, NIDA, Bethesda, MD; [3]Statistical and Scientific Computing Core, NIMH, Bethesda, MD; [4]Lab. of Clin. and Translational Studies, NIAAA, Bethesda, MD

Abstract: In humans, functional magnetic resonance imaging (fMRI) experiments have demonstrated that anticipation of instrumental responses for various rewards recruits the ventral striatum (VS). This has been attributed to activation of mesolimbic dopaminergic (DA) circuitry by cues for incentives, once cue-contingencies have been learned or trained. To confirm a causal role of dopaminergic functioning in human instrumental behavior, subjects responded to cues to win or avoid losing money in a monetary incentive delay (MID) task during temporary dietary restriction of DA precursor availability to the brain. In a repeated-measures, double-blind design, 16 healthy adults performed the MID task five hours after ingestion of one of two amino acid beverages in a counterbalanced order. The “depletion” (DEP) beverage consisted of large neutral amino acids (LNAA) that lacked catecholamine precursors Tyrosine (Tyr) and Phenylalanine (Phe). The “balanced” (BAL) amino-acid beverage included a proportionally-balanced amount of Tyr and Phe. Relative to pre-drink baseline, the DEP beverage caused a 94% reduction in the plasma (Tyr+Phe)/LNAA ratio at the time of scanning, while the BAL drink caused a modest 15% decrease. However, there were no dose differences in self-reported mood or in MID task reaction times. However, relative to the BAL beverage, the DEP beverage halved the peak modeled BOLD signal recruitment by large MID task rewards in a volume-of-interest anatomically localized in the VS, and also resulted in blunted patterns of brain-wide activation that did not reach a significant dose difference. In addition, notification of losses activated anterior insula under DEP conditions, but not BAL conditions. These data suggest that

mesolimbic incentive-related circuitry in humans is physiologically sensitive to changes in dopamine precursor availability, but the system maintains significant reserve or buffering capacity to resist a concomitant effect on behavior.

Title: Effects of perinatal delta-9-tetrahydrocannabinol (THC) exposure on brain c-Fos immunoreactivity following the reinstatement of morphine conditioned place preference by THC

Authors: *G. WILLEMS, P. E. MALLET
Psychology, Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Early life experiences, which occur during critical periods of development, are thought to influence vulnerability to adulthood drug addiction. While perinatal THC exposure has been shown to exacerbate the rewarding qualities of opioids in adulthood, exposure to an enriched environment (EE) during adolescence is implicated in the inhibition of adulthood opioid reward. Here, we intend to demonstrate that animals perinatally exposed to THC show differential degrees of morphine reward in adulthood dependent on housing in an enriched or standard environment (SE).Perinatal THC injections (5 mg/kg, subcutaneous) were administered from post-natal day 4 to 14, a time period which is reflective of the third trimester of human gestation. Animals housed in SE are expected to establish a more salient conditioned place preference (CPP) and take longer to extinguish morphine CPP (5 mg/kg, intraperitoneal) compared to animals housed in EE indicating that EE may have a protective effect against perinatal THC exposure. Furthermore, it is expected that THC will reinstate an extinguished morphine-induced CPP following a priming dose of THC (0.75 mg/kg, intraperitoneal) in animals perinatally exposed to THC, but not in untreated controls suggesting perinatal THC exposure increases cross-sensitization of animals to opioids. Neural activity in several brain regions associated with the mesocorticolimbic dopamine pathway (shell and core of nucleus accumbens, dorsomedial caudate putamen, dorsolateral periaqueductal gray, ventral tegmental area, and the bed nucleus of the stria terminalis) will be examined using c-Fos immunohistochemistry following the reinstatement of the extinguished morphine CPP. Based on

previous research conducted in our lab, it is expected that some regions will exhibit an increase in neural activity due to perinatal THC exposure, while other regions will have decreased c-Fos expression. These expected changes in c-Fos immunoreactivity may elucidate the underlying neural correlates of the observed changes in the rewarding properties of opiates due to perinatal THC exposure and environmental complexity.

Title: Amphetamine modulates fMRI BOLD response during active risk-taking in healthy young adults.

Authors: K. MILMAN[1], L. H. SWEET[2], M. WORDEN[1], R. A. COHEN[2], *T. L. WHITE[3]
[1]Neurosci., [2]Dept of Psychiatry and Human Behavior, [3]Ctr. for Alcohol & Addiction Studies, Brown Univ., PROVIDENCE, RI

Abstract: Amphetamine is a psychostimulant used for treatment of ADHD, and for military air operations because it increases alertness and attention. Clinical evidence suggests that impulsivity increases after drug consumption in addicted individuals. This increase in impulsive behavior could facilitate the transition to drug abuse through increased drug exposure in vulnerable young adults. To date, however, brain mechanisms involved in the effects of drugs on impulsive behavior are not well understood in healthy individuals. Objective: The present study was designed to determine the brain regions involved in acute drug effects on impulsive behavior, as measured using fMRI and a computerized measure of risk-taking behavior (Balloon Analogue Risk Task, BART) in healthy young adult volunteers. Methods: Healthy participants (N=52; 18-35 years) performed 4 runs of the BART during fMRI using standard echo planar conditions, 90 minutes after consumption of 20 mg d-amphetamine or placebo on two separate test days in a double-blind, within-subjects design. Results: Preliminary analyses (*n*=46) indicate significant drug effects on regions involved in attention, default network, and reward approach. During high incentive trials, BOLD response was elevated in midline thalamus, right parahippocampal gyrus, and right cerebellum ($p \leq 9.5 \times 10^{-4}$, FDR corrected p-value $\leq .05$,

cluster sizes > 150 voxels) after consumption of amphetamine compared to placebo, suggesting stimulant augmentation of activity in regions involved in emotional gating and volitional approach. BOLD responses to cash-out choices during the task were elevated in right lentiform nucleus/ right putamen, right posterior cingulate and left precentral gyrus after consumption of amphetamine compared to placebo, suggesting a facilitation of volitional motor approach of reward under drug ($p \leq 3.3 \times 10^{-5}$, FDR corrected p-value $\leq .05$). In contrast, BOLD responses in regions involved in spatial attention, sensory attention, and default mode network appeared to be reduced after amphetamine compared to placebo during the high incentive trials (right postcentral gyrus/ BA 40, left cuneus, bilateral lingual gyrus, left superior parietal lobule, left superior temporal gyrus, $p \leq 9.5 \times 10^{-4}$, FDR corrected p-value $\leq .05$). Conclusions: These data suggest that amphetamine selectively heightens the processing of relatively salient, impulsivity-relevant reward targets in ways that facilitate an internally-generated pattern of reward approach, within the larger context of reduced processing of unrelated external cues. Title: Effects of orexin receptor antagonism on methamphetamine seeking in adolescent and adult rats

Authors: *N. E. ZLEBNIK, N. A. HOLTZ, M. E. CARROLL
Univ. of Minnesota, Minneapolis, MN

Abstract: Previous studies have shown enhanced vulnerability to addiction in adolescent (vs. adult) as well as female (vs. male) rats. The orexin system recently has been implicated in addiction and reward processing, with orexin receptor blockade more effective in reducing drug seeking in male vs. female rats. However, to date, it is not known whether there are age differences in orexin antagonism of drug seeking. In the present study, we investigated treatment

of methamphetamine (METH) seeking in both adolescent (PND 23-60) and adult (> PND 90) male and female rats using selective orexin-1 receptor (Orx1A, SB-334867, 20 mg/kg) and orexin-2 receptor (Orx2A, TCS OX2 29, 20 mg/kg) antagonists. Rats were trained to self-administer METH (0.05 mg/kg/inf, iv) during two 2-h sessions/day for 5 days. Subsequently, auditory and visual stimuli that signaled drug delivery were unplugged, and rats were allowed to extinguish lever pressing for 20 additional sessions over 10 days. Next, a within-subjects design was used to test for METH seeking precipitated by METH (1 mg/kg, ip) or METH-paired stimuli following systemic (ip) pretreatment with Orx1A or Orx2A. Preliminary results indicate no sex differences in METH self-administration, extinction responding, or reinstatement responding under these conditions. In agreement with prior work, both Orx1A and Orx2A failed to significantly reduce METH-elicited reinstatement. However, both Orx1A and Orx2A worked equally well to reduce METH-paired cue-elicited reinstatement. These results extend previous work to show a role for orexin signaling in cue-induced, but not METH-induced, reinstatement of METH seeking behavior.

Title: The effect of relaxin-3 related antagonists on alcohol seeking

Authors: *P. J. RYAN[1], H. KASTMAN[1], E. V. KRSTEW[1], K. J. ROSENGREN[2], M. A. HOSSAIN[1], J. D. WADE[1], A. L. GUNDLACH[1], A. J. LAWRENCE[1]
[1]Florey Neurosci. Inst., The University of Melbourne, Australia; [2]Inst. for Mol. Biosci., Queensland, Australia

Abstract: Alcohol use and abuse is a major cause of morbidity and mortality, accounting for an estimated 4% of all global deaths and 5% of the global burden of disease and injury. Despite the huge impact of alcohol use disorders on society, current first-line therapeutic agents, such as naltrexone are inadequate, with high relapse rates and compliance problems. New therapeutic agents are required, particularly for the reduction of hazardous drinking and prevention of

relapse, which represent the most difficult clinical problems. Relaxin-3 is a highly conserved brain neuropeptide and its cognate G-protein coupled receptor is RXFP3. Relaxin-3/GABAergic neurons in hindbrain project widely to forebrain areas that express high levels of RXFP3, including amygdala, hippocampus and hypothalamus. This anatomical data and findings that relaxin-3 can modulate food intake, stress responses, and interact with CRF systems, supports the hypothesis that relaxin-3 may modulate drug seeking behavior (1). In studies using a model of alcohol use and alcohol-seeking in alcohol-preferring (iP) rats, we demonstrated that central administration of RXFP3 antagonists (3-30 µg, icv) decreased self-administration of alcohol in a dose-related manner (1-way ANOVA, $F(4,70) = 10.28$, $p < 0.0001$) and attenuated cue-induced reinstatement following extinction (1-way RM ANOVA, $F(2,26) = 30.07$, $p < 0.0001$). By comparison, RXFP3 blockade (10 µg, icv) produced no significant change in self-administration of sucrose, suggesting a selective effect for alcohol. Interestingly, RXFP3 antagonists decreased cue-induced reinstatement following extinction for sucrose and alcohol (1-way RM ANOVA, $F(2,30) = 13.96$, $p < 0.0001$), suggesting RXFP3 blockade may reduce reward-seeking behavior more generally. RXFP3 antagonist treatment had no effect on general ingestive behavior, activity, or cognition in the paradigms used. These data suggest relaxin-3/RXFP3 signaling regulates alcohol intake and relapse-like behavior, adding to current knowledge of the brain chemistry of reward-seeking. Further experimentation is required to determine the neural circuits and signaling mechanisms involved and to investigate effects on other drugs of abuse.

Title: Examining the role of fenfluramine and sibutramine treatment on cue-induced reinstatement of food-seeking behaviors in the rat

Authors: *W. E. PRATT, R. T. FORD
Dept. Psychology, Wake Forest Univ., WINSTON-SALEM, NC

Abstract: Individuals struggling with obesity often have difficulty maintaining dietary regimens. One source of dietary relapse is the reinstatement of previous feeding behaviors following the presentation of cues indicating the availability of palatable and highly caloric food reward. The drugs sibutramine and fenfluramine have been previously prescribed because they enhance satiety mechanisms and decrease meal size. However, it is unclear whether these anorectic agents are also effective in blocking the cue-induced reinstatement of food-seeking behaviors. In these experiments, three separate groups of rats (N = 12/group) were food-deprived and trained to lever press for sugar pellets in the presence of a light/tone cue according to procedures developed by Floresco, McLaughlin, and Haluk (2008). Once trained, rats underwent daily 20-min extinction sessions in which lever press resulted in no programmed consequences. Upon extinguishing to 10% of their pre-extinction performance, rats received two separate reinstatement sessions following drug or saline injections (counterbalanced across rats and separated by 48 hr) in which lever pressing resulted in delivery of the light/tone cue. 30 min prior to these reinstatement tests, rats received IP injection of saline or the selective D_1 receptor antagonist SCH 23390 (6 microgram/kg, Experiment 1), fenfluramine (3 milligrams/kg, Experiment 2), or sibutramine (3 milligrams/kg, Experiment 3). Consistent with previous reports (Ball, Combs, & Beyer, 2011), rats did not reinstate lever pressing relative to their final day of extinction following systemic injections of the D_1 antagonist. Similarly, fenfluramine treatment blocked the cue's ability to reinstate lever pressing as compared to the saline injection day. However, there was no difference in lever pressing across extinction, drug, and saline days within the sibutramine group; all animals reinstated their lever pressing during the first reinstatement test, and this was unaffected by sibutramine treatment. These experiments suggest that the effect of fenfluramine is not limited to the promotion of satiety once a meal has been initiated, and demonstrate that some anorectic treatments may inhibit the effectiveness of conditioned cues to elicit relapse into food-seeking behavior. As continued effort is placed into developing pharmacotherapy for weight loss, it will be of interest to determine the effectiveness of anorectic drugs upon cue-induced relapse, across both animal models and within human diet regimens.

Title: Effects of triazolam on caudate and nucleus accumbens dopamine levels at doses that are self-administered by rhesus monkeys.

Authors: *E. K. SAWYER[1], K. S. MURNANE[2], L. L. HOWELL[2], J. K. ROWLETT[1]
[1]Div. of Neurosci., New England Primate Res. Center, Harvard Med. Sch., Southborough, MA; [2]Div. of Neuropharm. and Neurologic Dis., Yerkes Natl. Primate Res. Center, Emory Univ., Atlanta, GA

Abstract: Benzodiazepines are abused widely, yet the neurobiological basis for this effect is poorly understood. It has been proposed that, as with other drugs of abuse, an increase in dopamine (DA) release in the nucleus accumbens underlies benzodiazepine self-administration. However, there is to date no direct evidence documenting such an increase and, in fact, benzodiazepines may decrease extracellular DA levels in rodents. Therefore, we examined the reinforcing and neurochemical effects of triazolam in rhesus monkeys. We first determined doses of the representative benzodiazepine triazolam that were reliably self-administered above vehicle levels. In this study, triazolam (0.0003-0.03 mg/kg/injection) was available to adult monkeys (n=4) for self-administration under a progressive ratio schedule of i.v. drug delivery. Triazolam maintained self-administration levels significantly greater than vehicle at unit doses of 0.003 and 0.01 mg/kg/injection (average numbers of injections/session= 11.7 and 10, respectively). The total cumulative dose was calculated as the unit dose (mg/kg/injection) x average number of injections/session, resulting in total cumulative dose values of approximately 0.035 and 0.1 mg/kg. In a separate group of adult monkeys (n=4), doses equivalent to the total cumulative dose values for triazolam were evaluated for changes in extracellular DA levels in the caudate and nucleus accumbens using in vivo microdialysis. Cocaine (1 mg/kg, i.v.) served as a positive control. DA levels in the caudate were not significantly affected following 0.03 or 0.1 mg/kg, i.v., of triazolam. However, DA levels in the nucleus accumbens were significantly decreased following 0.1 mg/kg triazolam. Cocaine significantly increased extracellular DA in the nucleus accumbens in all animals. Together, these data suggest that the mechanism(s) underlying the reinforcing effects of benzodiazepines may differ from that of other abused drugs and form the basis for further studies investigating the neurochemical correlates of benzodiazepine abuse.

Title: Attenuation of nicotine-induced alterations in dopamine signaling during adolescence via 5-HT1A receptor antagonism

Authors: *M. YUAN, C. A. FENG, A. J. CABRERA, J. J. ZENG, J. D. BELLUZZI, F. M. LESLIE
Pharmacol., Univ. of California - Irvine, Irvine, CA

Abstract: Adolescence is a developmental transition period when the initiation of tobacco use and the onset of neuropsychiatric disorders most often emerge. Nicotine exposure during this vulnerable period may elicit long-lasting biochemical alterations in brain signaling and development, potentiating the likelihood for substance abuse. Previous studies in our lab have implicated serotonin (5-HT), acting via 5-HT1A receptors, as a mediator of nicotine-induced alterations of dopamine (DA) signaling during adolescence (Dao et al., 2011). Brief, low dose nicotine exposure in adolescent rats enhances acquisition of cocaine self-administration, an effect blocked by WAY-100,635 (5-HT1A antagonist). Furthermore, this adolescent nicotine treatment enhances sensitivity to direct DA agonists, increasing locomotor activity induced by quinpirole (D2-like agonist), an effect mimicked by 8-OH-DPAT (5-HT1A agonist) and blocked by co-administration of WAY-100,635 with nicotine. The present study was designed to determine whether 5-HT1A antagonism with WAY-100,635 can rescue alterations in the functional sensitivity of D2 receptors in adolescents after nicotine exposure. Nicotine (60µg/kg) was administered intravenously (i.v.) for four consecutive days in adolescent and adult male Sprague-Dawley rats. The following day, rats were treated with WAY-100,635 (100µg/kg i.v.) 20min prior to administration of quinpirole (0.4mg/kg, i.p.), and locomotor activity and erectile response were recorded. Acute administration of WAY-100,635 prior to D2 activation attenuated nicotine's age-specific enhancement of quinpirole-induced locomotion but not erectile response. These findings further implicate 5-HT1A receptor regulation of D2 signaling in adolescent brain and offer an exciting potential for the rescue of functional alterations in dopamine signaling following adolescent nicotine exposure.

Title: Methamphetamine-induced conditioned place preference in C3H/HeN mice is observed during the day (ZT 6-8) but not at night (ZT 19-21).

Authors: *S. J. CLOUGH[1], A. J. HUTCHINSON[1], I. STEPIEN[1], R. L. HUDSON[2], M. L. DUBOCOVICH[1]
[1]Pharmacol. and Toxicology, [2]Physiol. and Biophysics, Univ. At Buffalo Sch. of Med. and Biomed. Sci., Buffalo, NY

Abstract: Methamphetamine (METH) has been extensively studied for its ability to produce reward through its action on the mesolimbic dopamine system. The pineal hormone melatonin is synthesized following a circadian rhythm, with low levels during the day and high levels at night (Reiter, *Mol Cel Endocrinol* 1991;79:C153-C158). Melatonin exerts its effects through action on two G-coupled protein receptors, the MT_1 and MT_2, which are located in several brain regions including areas of the reward pathway (UZ *et al*., Mol Brain Res 2005, 136:45-53). During the day (Zeitgeber Time [ZT] 6-8; 12h:12h light-dark cycle, ZT 0 = lights on) METH (1.2 mg/kg, ip) induces a strong conditioned place preference in C3H/HeN wild-type mice. However deletion of either the MT_1 or MT_2 melatonin receptor blocks this effect, suggesting a role for melatonin in the modulation of METH-induced reward. The goal of this study was to examine the contributions of endogenous melatonin in the modulation of METH-induced place preference by comparing preference scores at ZT 6-8 and ZT 19-21 when melatonin is low and high respectively. Male C3H/HeN wild-type mice were subjected to a conditioned place preference test during ZT 6-8 and ZT 19-21. Compartment duration was measured during the drug-free habituation and pre-test sessions using LocoScan System (Clever Inc, Reston, VA). Animals were conditioned for 6 days with alternating treatments of METH (1.2 mg/kg, ip) and vehicle (VEH) and tested for place preference 1 day after the last conditioning session. A preference score was derived by subtracting the duration spent in the VEH-paired compartment from the duration spent in the METH-paired compartment during the post-test. At ZT 19-21 mice exhibited a similar preference score regardless of receiving METH (70.1$\pm$37.8 s, n=17) or VEH (23.3$\pm$21.5 s, n=17). This is in stark contrast to mice tested at ZT 6-8, which displayed a strong place preference for METH (226.0$\pm$35.5 s, n =11, $p<0.001$) compared to VEH controls (-

36.3±28.1 s, n=12). This time dependent difference suggests the involvement of a regulatory mechanism subject to a circadian rhythm, such as melatonin, which may act through inhibition of long-term potentiation (Wang *et al*., Eur J. Neuroscience 22:22-31, 2005). *Supported by DA 021870 to MLD*

Title: Comparative effects of lithium and antidepressants in a rat model of anhedonia

Authors: *C. GAMBARANA, S. SCHEGGI, A. FERRARI, M. DE MONTIS
Univ. of Siena, SIENA, Italy

Abstract: Anhedonia, a key symptom of major depression, defines the inability to experience pleasure from normally pleasurable life events. The reduced hedonic capacity of depressed patients may not be solely sustained by a reduced capacity to experience pleasure, but also by an inability to emit positive behavioral responses to pleasurable stimuli. Repeated exposure to unavoidable stress induces in rats an escape deficit to avoidable stressors, disrupts the dopaminergic response in the nucleus accumbens shell (NAcS) to palatable food consumption and competence to acquire an instrumental behavior sustained by palatable food. The phasic increase in NAcS dopamine output in response to a relevant stimulus confers incentive salience to the stimulus representation. Non food-deprived rats exposed to repeated unavoidable stress don't learn to choose the baited arm in a T-maze and to self-administer sucrose pellets under FR1 or FR5 schedule, and under a progressive response (PR) schedule of reinforcement, that is a measure of reward strength. Thus, repeated stress exposure conforms to the criteria for an experimental anhedonia model. We studied the effects of repeated lithium administration on sucrose self-administration (SA) in anhedonic rats using the following experimental protocol: after a 7-day stress exposure, rats were trained for SA with the FR1 schedule, then underwent 3 training sessions with the FR5 schedule, while continuing stress exposure. Control rats were trained in parallel. At day 21 stressed rats were divided in 2 groups: saline- and lithium-treated, while continuing stress exposure. After 7 days of treatment, rats were exposed to a single SA

session with the FR1 schedule, 5 sessions with the FR5 schedule and then to 3 sessions with the PR schedule while continuing treatments and stress exposure. Lithium treatment reverted the stress-induced learning deficit and reinstated the PR score, i. e. the reward and incentive values of sucrose, to control values in chronically stressed rats. Using the same experimental protocol, different results were obtained in rats treated with fluoxetine (FLX) as this treatment failed to modify the disruptive effects of unavoidable stress on the competence to acquire sucrose-sustained SA and escape response. We previously demonstrated that administration of imipramine, FLX, or lithium for 1-2 weeks before stress exposure and during behavioral training under stress prevent the development of the neurochemical (lack of dopaminergic response to a palatable meal) and behavioral deficits. Thus, FLX prevents the development of stress-induced disruption of SA, while lithium also reverted an established anhedonia condition.

Title: Potential of partial negative allosteric modulators of the metabotropic glutamate receptor subtype 5 for reversal of cocaine self-administration in rats.

Authors: *R. J. AMATO, IV[1,2], M. E. JOFFE[1,2], R. D. MORRISON[1,2], A. L. RODRIGUEZ[1,2], A. S. FELTS[1,2], K. A. EMMITTE[1,2], J. S. DANIELS[1,2], P. J. CONN[1,2], C. W. LINDSLEY[1,2,3], C. K. JONES[1,2]
[1]Ctr. for Neurosci. Drug Discovery, [2]Dept. of Pharmacol., [3]Dept. of Chem., Vanderbilt Univ., Nashville, TN

Abstract: Recent evidence indicates that the metabotropic glutamate receptor subtype 5 ($mGlu_5$) plays an important role in the modulation of the rewarding effects of various drugs of abuse, including cocaine. For example, $mGlu_5$ knockout mice do not self-administer cocaine and are insensitive to other cocaine-induced behavioral changes. Moreover, selective negative allosteric modulators (NAMs) of $mGlu_5$ can attenuate cocaine self-administration in animals. Unfortunately, first generation full $mGlu_5$ NAMs, including MPEP, are associated with dose-limiting adverse effects, including psychotomimetic-like activity and cognitive impairments,

which limit their therapeutic potential. We have recently discovered a chemical series with several partial mGlu5 NAMs that act by partially blocking the maximal activation of $mGlu_5$ by glutamate in a calcium mobilization assay and exhibit a range of activities from 10% maximal inhibition to 90% maximal inhibition of the glutamate response. Compounds within this series also bind to the allosteric MPEP site on $mGlu_5$ and exhibit favorable pharmacokinetic properties for systemic administration in animals. For the behavioral studies, male Sprague Dawley rats were trained to respond under a schedule of cocaine self-administration and were administered vehicle or a dose of either a full or partial $mGlu_5$ NAM (1-30 mg/kg) prior to each test session. During each session, responding (lever press) under a fixed-ratio (FR)-10 resulted in the delivery of 0.5 mg/kg/infusion cocaine. Dependent measures of responding under this schedule were the total number of infusions and response rate (response/minute). Preliminary findings indicate that varying degrees of $mGlu_5$ inhibition of the full and partial $mGlu_5$ NAMs produce dose-related decreases both in the rate of responding for cocaine and the total number of infusions earned per session. The dose-related efficacy in the cocaine self-administration paradigm was correlated with the degree of central $mGlu_5$ occupancy and the potential to disrupt performance in a cognitive task of memory function. These novel partial $mGlu_5$ NAMs provide important tool compounds to establish whether partial inhibition of $mGlu_5$ is sufficient to produce efficacy in preclinical models of cocaine self-administration and seeking behaviors without the associated side-effects observed with first generation, full $mGlu_5$ NAMs.

Title: Evaluation of the effects of withdrawal from acute pcp on progressive ratio responding-relevance to negative symptoms of schizophrenia?

Authors: *K. M. DLUGOLENSKI, R. GRAF, Z. A. HUGHES
Psychiatry & Behavioral Disorders, Neurosci. Res. Unit, Pfizer Global Res., Cambridge, MA

Abstract: Negative symptoms of schizophrenia such as lack of motivation or drive are largely untreated by typical and atypical antipsychotics. As this symptom domain involves reward

circuitry, the challenge is to specifically address deficits in motivation without causing increased responding in healthy subjects which could raise concerns regarding abuse liability. Therefore, identification of preclinical models which recapitulate deficits in motivation observed in schizophrenia would be of great value. Given the NMDA-hypofunction model of schizophrenia, one manipulation with potential relevance is withdrawal from an acute NMDA antagonist. Spielewoy and Markou (Neuropsychopharmacology, 2003, 1106-1116) used intracranial self stimulation (ICSS) to demonstrate increased reward threshold 8, 12 and 24 h after a single dose of phencyclidine (PCP). Here we have investigated whether this protocol also affects progressive ratio responding.

All studies were performed in accordance to the Guide for the Care and Use of Laboratory Animals as adopted and promulgated by the NIH(Pub. 85-23, revised 1996) and approved by the Institutional Animal Care and Use Committee (IACUC). Adult male Sprague Dawley rats were trained to lever press for a food reward on a progressive ratio schedule. Progressive ratio responding was assessed 21 h after administration of PCP (5 mg/kg s.c.) or vehicle. Rats dosed with PCP exhibited decreases in all response measures (breakpoint, rewards, active lever presses, inactive lever presses) as well as moderate decreases in general locomotor activity. Using a cross-over design, the ability of D-cycloserine to reverse these effects was tested. D-cycloserine (32 or 100 mg/kg s.c.) was administered to vehicle or PCP treated rats 30 minutes prior to assessing progressive ratio responding. Neither dose of D-cycloserine affected responding in vehicle treated rats or attenuated the deficit caused by PCP treatment.

D-cycloserine was tested due to the clinical reports suggesting efficacy against negative symptoms in schizophrenia (Goff et al, Schizophrenia Bulletin, 2008, 106(2-3): 320-327). This treatment has not been studied extensively in patients so it is far from a ‘gold standard’ treatment for negative symptoms. A number of novel mechanisms (e.g. D-amphetamine prodrugs, GlyT inhibitors, glycine site agonists) are being evaluated in clinical trials, some of which are showing early signals of efficacy. Additional preclinical testing of such mechanisms is required to determine whether reversal of PCP-induced deficits in progressive ratio responding has value in predicting efficacy in negative symptoms of schizophrenia.

Title: An examination of the effects of serotonin 2A, 2B, and 3 receptor activation of the nucleus accumbens on feeding behavior in the rat

Authors: *P. LIN, K. A. CLISSOLD, C. P. LEWIS, X. ZHU, W. E. PRATT
Dept. of Psychology, Wake Forest Univ., Winston Salem, NC

Abstract: Central serotonin (5-HT) signaling has been widely implicated in the regulation of feeding behaviors in both humans and animal models. We have previously reported that individual serotonin receptors of the medial nucleus accumbens regulate feeding and food-directed motivation. For example, nucleus accumbens stimulation of the 5-HT_{1A} receptor inhibits feeding behavior, whereas activation of the 5-HT_6 receptor increases food intake and the effort that rats will exert to earn sugar reinforcement. The current experiments sought to further examine the role of individual serotonin receptors by testing the effects of pharmacological manipulation of the 5-HT_{2A}, 5-HT_{2B}, and 5-HT_3 receptors within the anterior medial nucleus accumbens on feeding in hungry rats. Male Sprague-Dawley rats were acclimated to laboratory conditions and surgically implanted with bilateral guide cannulas above the nucleus accumbens shell. After recovery, the rats were food deprived to 90% of their ad libidum body weight and habituated to 2-hour feeding sessions during which they had free access to rat chow and water. Food consumption, water intake, ambulation, and rearing behaviors were monitored throughout each session. Across multiple experimental days, individual groups of rats (N= 7-8/group) received counterbalanced bilateral injections of one of the following selective serotonergic agents into the medial nucleus accumbens prior to being placed into the food intake chambers: the 5-HT_{1A} agonist TCB-2 (at 0.0, 1.0, 5.0, and 10.0 microg/0.5 microl/side); the 5-HT_{2B} agonist BW 723C86 (at 0.0, 2.0 and 5.0 microg/0.5 microl); or the 5-HT_3 agonist m-chlorophenylbiguanide (at 0.0, 10.0, 20.0 and 40.0 microg/0.5 microl). Stimulation of the 5-HT_{2A} receptor modestly increased ambulation, but had no effect on food intake across the 2 hr session. In contrast, stimulation of either the 5-HT_{2B} or the 5-HT_3 receptor subtype increased food intake across time without significantly affecting measures of locomotion or water intake. In separate experiments, blockade of these receptor subtypes had no effect on feeding behavior. Together, these results contribute to a growing understanding of the function of individual serotonin receptors within the nucleus accumbens on food-motivated behavior, and suggest that individual serotonin receptor subtypes serve unique behavioral roles within ventral striatal circuitry.

Title: Neuropeptide Y Y1 receptors in the bed nucleus of the stria terminalis modulate binge-like ethanol consumption by C57BL/6J mice.

Authors: *E. G. LOWERY[1], T. E. THIELE[1,2], T. L. KASH[1,3]
[1]Bowles Ctr. for Alcohol Studies, [2]Dept. of Psychology, [3]Dept. of Pharmacol., Univ. of North Carolina, Chapel Hill, NC

Abstract: Recent evidence suggests that neuropeptide Y (NPY) modulates binge-like ethanol consumption via the Y1 and Y2 receptors (R). The brain regions that are involved in this behavior have not been elucidated, though regions of the extended amygdala, such as the bed nucleus of the stria terminalis (BNST), are known to be critical for behavioral and neurophysiological phenotypes associated with ethanol dependence. Therefore, we investigated the role of NPY Y1R in the BNST in binge-like ethanol consumption by bilaterally infusing the Y1R agonist [Leu31,Pro34]-Neuropeptide Y (LeuPro; 0.42 µg/0.5 µl) into the BNST of male C57BL/6J mice one hour prior to binge-like ethanol consumption. Mice treated with LeuPro displayed significantly lower levels of ethanol consumption than vehicle-treated mice (3.32 ± 0.76 vs. 5.17 ± 0.31 g/kg/4h, respectively) and achieved blood ethanol concentrations (BECs; 65.43 ± 25.45 mg/dl) below both the NIAAA-defined level characteristic of binge drinking (≥ 80 mg/dl) and the levels achieved by the vehicle-treated mice (108.53 ± 18.89 mg/dl). Importantly, bilateral infusions of LeuPro did not impair locomotor activity. These results demonstrate that Y1Rs of the BNST are involved in regulating binge-like ethanol consumption and provide the first direct evidence that NPY signaling in the BNST has a role in the modulation of ethanol intake. Future studies will assess the role of Y2Rs in the BNST in binge-like ethanol consumption.

Title: The effects of rearing condition and chronic methylphenidate treatment on anxiety-like behavior and ethanol consumption

Authors: *K. E. GILL, A. CHAPPELL, J. WEINER, L. J. PORRINO
Physiol. Pharmacol., Wake Forest Univ. Sch. of Med., Winston Salem, NC

Abstract: Methylphenidate (MPH) is the most commonly prescribed medication in childhood, with an estimated 5-6% of children using it as treatment for Attention Deficit Hyperactivity Disorder. However, the drug's long term effects on the dopamine (DA) system and future vulnerability to substance abuse remain unclear. Previously we found that chronic administration of 8 mg/kg/day MPH for three weeks during pre- and peri-adolescence significantly reduced the density of DA D2/D3 receptors in the striatum of young rats. Low D2/D3 receptor density is associated with increased vulnerability to alcohol abuse. Additionally, environmental rearing conditions are known to affect future vulnerability to alcohol abuse, with isolation during early development increasing future ethanol intake. Here we examined the effects of MPH treatment and early rearing condition on anxiety-like behavior and two-bottle choice ethanol drinking in adulthood. Forty-eight young (PND 21) male Sprague Dawley rats (n = 16/housing group) were assigned to isolated (I), pair-housed (PH), or environmentally enriched (EE) conditions for 4 weeks. During 3 of those weeks, 8 rats per group received 8 mg/kg/day MPH via ALZET© osmotic mini-pump. At PND 50, rats were tested for anxiety-like behavior on the elevated plus maze. Subsequently, rats were individually housed and began a two-bottle choice ethanol drinking procedure that lasted 5 weeks. For one hour each day, rats had access to two bottles: one containing a 1% sucrose/8% ethanol solution and the other containing water. Total intake (g/kg ethanol) was calculated. There was a significant effect of housing on anxiety-like behavior ($F_{2,42} = 8.961$, $p < 0.001$). Isolated rats had significantly greater expression of anxiety-like behavior than PH or EE rats. A three-way analysis of variance (day*drug*housing condition) showed a significant interaction of drug*housing condition ($F_{2,42} = 4.626$, $p < 0.02$) on total intake of ethanol over the course of the procedure. Post-hoc tests confirmed that MPH increased ethanol intake in I rats only. Pair-housed and EE rats drank similar amounts of ethanol regardless of drug treatment. Previous studies have shown that isolation housing increases both the expression of anxiety-like behavior and ethanol intake. Here, while isolation did increase

anxiety-like behavior, only I rats that were treated with methylphenidate had greater ethanol intake than other groups. Thus, while 4 weeks of isolation alone during adolescence was not sufficient to alter drinking, the addition of a drug known to lower DA D2/D3 receptor density in reward related brain regions did increase vulnerability to alcohol drinking in adulthood.

Title: Effects of dopamine beta-hydroxylase (DBH) inhibition on cocaine seeking behavior in squirrel monkeys

Authors: *D. A. COOPER[1,2], H. L. KIMMEL[2], L. L. HOWELL[2]
[1]Emory Univ., Atlanta, GA; [2]Neurosci., Yerkes Natl. Primate Res. Ctr., Atlanta, GA

Abstract: Disulfiram (Antabuse) has shown promise in clinical trials as a pharmacotherapy for cocaine dependence. One of many biochemical actions of disulfiram is inhibition of dopamine beta-hydroxylase (DBH), the enzyme that converts dopamine to norepinephrine (NE); consequently, reducing brain NE levels**.** It is believed that this mechanism is responsible for the therapeutic effects of disulfiram. Noradrenergic signaling is required for reinstatement of drug seeking in rats, a paradigm which is thought to model drug relapse. In rats, disulfiram blocks cocaine-primed reinstatement, corroborating with clinical results. Furthermore, nepicastat, a selective DBH inhibitor also blocks cocaine-primed reinstatement in rats, supporting the therapeutic use of DBH inhibitors. In this study, we attempted to replicate these results in non-

human primates. Squirrel monkeys trained to self-administer cocaine under a second-order schedule were pretreated with disulfiram or nepicastat prior to cocaine-primed reinstatement sessions. Neither pretreatment altered cocaine-primed reinstatement. Unexpectedly, nepicastat alone was sufficient to induce a modest reinstatement effect. We are currently assessing the extracellular neurochemical effects of nepicastat in squirrel monkeys using in vivo microdialysis to corroborate with the behavioral results we have found. Additionally, the discrepancies found between squirrel monkeys and rats may be explained by differences in pharmacokinetic or metabolic profiles in the two species. Ongoing studies are investigating whether metabolic differences are present, which will ultimately be instrumental in influencing the translation of these therapies to a human population.

Title: Iptakalim attenuates the stimulus and reinforcing effects of nicotine in rats.

Authors: *S. CHARNTIKOV[1], S. PITTENGER[1], N. SWALVE[1], K. FINK[1], S. SCHEPERS[1], M. LI[1], G. HU[2], R. BEVINS[1]
[1]Dept of Psychology, Univ. of Nebraska-Lincoln, Lincoln, NE; [2]Nanjing Med. University, Nanjing, Nanjing, China

Abstract: Smoking and its associated nicotine dependence remains a significant health problem worldwide. Although advancements in treatment have been made in recent years, the high relapse rate indicates a need for continued research into potential therapeutics. Iptakalim, approved in China to treat hypertension, is an ATP sensitive potassium channel opener and an antagonist for alpha4-beta2 containing nAChRs. Further, pretreatment with iptakalim diminishes dopamine and glutamate release induced by nicotine. This neuropharmacological profile suggests that iptakalim may be used to treat smoking. To this end, in one study, we assessed whether iptakalim would block the stimulus effects of nicotine. Rats first received discrimination training with intermixed nicotine (0.4 mg/kg, SC) and saline sessions. Sucrose was intermittently presented in a response-independent manner only on nicotine session. Upon stable discrimination performance, greater anticipatory dipper entries (goal-tracking) on nicotine than saline sessions,

rats were tested for whether pretreatment with iptakalim (10, 30, 60 mg/kg, IP) blocked responding evoked by nicotine. Iptakalim blocked responding in a dose-dependent manner. Further, simultaneous collection of chamber activity indicated that iptakalim also blocked the locomotor stimulant effects of nicotine. When iptakalim was given alone, baseline chamber activity and goal-tracking was not affected, decreasing the feasibility of an account based on a non-specific effect of iptakalim. In a separate study, rats were prepared with IV catheters and then trained to self-administer nicotine (0.03 mg/kg/infusion) on a VR3 schedule of reinforcement. Pretreatment with iptakalim (1, 3, 6 mg/kg, IV) decreased the intake of nicotine (i.e., less active lever responding). Inactive lever presses were not affected by iptakalim. However, general chamber activity was attenuated by pretreatment with 3 and 6 mg/kg iptakalim. An analysis of covariance revealed that this reduction of activity did not significantly contribute to the decreased active lever presses. This suggests that the observed antagonism was not due to a non-specific effect. In sum, iptakalim blocked the stimulus, the reinforcing, and the stimulant effects of nicotine. Together, these finding support the notion that iptakalim may be an effective pharmacotherapy for increasing smoking cessation.

Title: Oxycodone-induced activation of Toll-Like Receptor 4 contributes to drug reward

Authors: *M. R. HUTCHINSON[1], K. VAN STEEG[2,3], J. THOMAS[2]
[1]Discipline of Physiol., [2]Discipline of Pharmacol., Univ. Adelaide, Adelaide, Australia; [3]Div. of Pharmacol., Utrecht Univ., Utrecht, Netherlands

Abstract: Traditional opioid action to create reward was thought to result solely via the initial agonism of neuronal opioid receptors. Previous studies have implicated proinflammatory immune signaling within the brain in potentiating the rewarding properties of opioids. However, the mechanism for the initiation of this proinflammatory central immune signal was unclear. Here we present evidence for an additional novel contributor to opioid reward: the innate immune pattern-recognition receptor, Toll-like receptor 4 (TLR4), and its MyD88-dependent

signaling as the trigger of the proinflammatory central immune signaling. Conditioned place preference for oxycodone was examined in wild-type Balb/c, *TLR4* $^{-/-}$ and *MyD88* $^{-/-}$ mice. Oxycodone (20 mg/kg) induced a 127 ± 31 sec change in preference for the oxycodone-paired environment, compared to 32 ± 32 sec for *TLR4* $^{-/-}$ and -25 ± 32 for *MyD88* $^{-/-}$ mice. Two-way ANOVA revealed significant effects of oxycodone ($p = 0.049$), strain ($p = 0.046$) and interaction ($p = 0.01$). Post-hoc Bonferroni multiple comparisons revealed a significant difference in the change in preference between oxycodone and saline conditioned wild-type mice ($p < 0.001$), but not in *TLR4* $^{-/-}$ or *MyD88* $^{-/-}$ mice ($p > 0.05$). Importantly, oxycodone-TLR4 actions were not a unidirectional suppressive influence on opioid pharmacodynamics. Hotplate latency dose responses were generated in wild-type and TLR4 $^{-/-}$ mice. There was a 5-fold leftward shift in the *TLR4* $^{-/-}$ oxycodone dose response curve (ED_{50} wild-type 1.36 mg/kg versus *TLR4* $^{-/-}$ 0.26 mg/kg; $P < 0.0001$) compared to wild-type mice. Moreover, immediately following behavioral testing in these mice their spinal cords were collected and quantification of the phosphorylation of Mitogen Activated Protein Kinases was performed. Oxycodone induced significant dose dependent p38 and JNK phosphorylation in wild type, but not *TLR4* $^{-/-}$ mice ($P < 0.05$). Collectively, these data indicate that the actions of opioids at classical opioid receptors, together with the newly identified actions at TLR4/MD2, possibly affects the mesolimbic dopamine system and may explain altered opioid reward behaviors. Thus, the discovery of TLR4/MD2 recognition of opioids as foreign xenobiotic substances (xenobiotic associated molecular patterns; XAMPs) adds to the existing hypothesized opioid reward mechanisms, identifies a new drug target in TLR4/MD2 for the treatment of addiction, and provides further evidence supporting a role for central inflammation in drug reward. Moreover, questioning whether XAMP-TLR4 activity contributes to the rewarding properties of diverse drugs of abuse now appears warranted.

Title: 5,7 dht lesions facilitate mdma self-administration

Authors: *S. SCHENK[1], S. BRADBURY[2]
[1]Victoria Univ. Wellington, Wellington, New Zealand; [2]Psychology, Victoria Univ. of Wellington, Wellington, New Zealand

Abstract: Our previous studies have shown that the acquisition of MDMA self-administration is relatively slow and a larger number of rats fail to meet acquisition criteria compared to other drugs of abuse. During the initial sessions, only a small number (1-2) infusions are self-administered. With repeated testing, however, there is an escalation of intake over days and eventually some rats self-administer 20-30 mg/kg/day during 2 or 6 hr test sessions. We have suggested that the preferential effects of MDMA on serotonin neurotransmission initially limits its self-administration. Following repeated exposure, however, tissue levels of 5HT decrease and the MDMA-produced increase in synaptic dopamine increases. We hypothesise that the increased DA response underlies the development of high rates of MDMA self-administration. This idea was tested in the present study by examining the effects of neurotoxic 5,7 DHT lesions on the acquisition of MDMA self-administration. Intracerebroventricular administration of 5,7 DHT produced an 80% decrease in tissue levels of 5HT in a number of brain sites. Acquisition of MDMA self-administration in control rats proceeded with a protracted time course, as we have reported. In this control group about half the rats failed to acquire self-administration within a 25 day cut-off period, as we have also previously reported. The lesioned rats, however, acquired self-administration more rapidly and all of the rats met the criterion for self-administration. These data support the idea that MDMA self-administration is, at least initially, limited by 5HT effects.

Title: Anatomical and functional organization of the mouse rostromedial tegmentum (RMTg)

Authors: *D. I. WASSERMAN, H. WANG, J. S. YEOMANS
Psychology, UNIVERSITY OF TORONTO, Toronto, ON, Canada

Abstract: Previous studies in rats found that activation of RMTg neurons can inhibit ventral tegmental area (VTA) dopamine output, and that opiates can inhibit these RMTg GABA neurons. Last year, we reported opposing effects of VTA versus RMTg activation on morphine-induced locomotion in mice. Transfecting the excitatory M5 muscarinic receptor into the VTA doubled the locomotor response to morphine. Conversely, transfecting the M5 receptor into the RMTg blocked the stimulant effect of morphine. We investigated the organization of the mouse RMTg and VTA and their connections. TH and GAD immunoreactivity was observed in VTA sites, but only GAD in the RMTg. The mouse RMTg was also rich in mu-opiate receptors specifically on GAD-positive neurons, as previously found in rat (Jhou et al, 2009).A strong projection from RMTg GABA neurons to VTA DA neurons has previously been reported in rats. To map the connections between these regions in mice, we injected cholera toxin B retrograde tracer into the VTA. While many areas of the brain displayed retrograde labeling, the strongest projections were from RMTg neurons. Specifically, the region that showed the strongest VTA projections, immediately dorsolateral to the caudal IPN, was the same location where morphine-induced locomotion was blocked. These data support the hypothesis that RMTg GABA neurons that inhibit VTA DA neurons are important for morphine-induced locomotion in mice.

Title: Effects of perinatal delta-9-tetrahydrocannabinol (THC) exposure and environmental complexity during adolescence on motivation, working memory and anxiety in rats

Authors: *A. CELEJEWSKI, G. WILLEMS, S. DANIELS, P. E. MALLET
Psychology Dept., Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Early life cannabinoid exposure has been shown to produce a broad range of behavioural and cognitive impairments. Among these are changes in reward system function, memory, and emotional reactivity. Furthermore, environmental enrichment during rearing has been shown to alter cognitive function in adulthood. The present study sought to determine if

environmental complexity during adolescence offered protection against the detrimental cognitive effects of early life cannabinoid exposure. Changes in motivation, working memory, and anxiety were examined in rats perinatally exposed to THC, then reared in either an enriched environment (EE) or standard environment (SE) during adolescence. Male Wistar rat pups received either daily injections of THC (5 mg/kg, s.c.) or its vehicle on postnatal days (PND) 4-14. Rats were weaned at PND21 and then reared in either SE or EE conditions until PND52. Beginning at PND81, animals were food restricted, and trained to lever press for food reward on a progressive ratio (PR) schedule to compare motivation for food reward across groups. Perinatally THC exposed rats displayed higher breakpoints, but no effect of rearing environment was observed. To assess working memory, performance on a delayed-matching-to-position (DMTP) task was assessed following administration of THC (0.1, 0.5, 1 or 2 mg/kg, i.p.) or its vehicle. We intend to determine if rearing environment exacerbates (SE) or ameliorates (EE) the detrimental impact of perinatal THC exposure. We will also examine baseline anxiety in the elevated plus maze and light dark emergence tests to determine if early life THC exposure and rearing conditions also affect emotional reactivity in adulthood.

Title: Impact of sub-chronic ketamine exposure on the reinforcing effects of nicotine in rats: Implications for self-medication in schizophrenia

Authors: *M. SHOAIB, N. HARUN
Inst. of Neurosci., Newcastle University, United Kingdom

Abstract: Cognitive deficits represent the core deficits within schizophrenia, accountable for the majority of disruption to everyday life. Over 80% of patients with schizophrenia smoke compared to just 30% of the general population. This is proposed as a form of self-medication to help combat cognitive problems as nicotine. Our laboratory has shown that a sub-chronic, sub-anaesthetic regimen of NMDA antagonist ketamine can induce cognitive deficits on a variety of cognitive domains such as memory capacity of working memory and executive decision-making in the attentional set-shifting task. The objective was to examine the effects of treating rats with ketamine (daily injection of 30mg/kg IP for 5 days) on acquisition to self-administer intravenous

nicotine (0.03mg/kg/inj) using two-lever operant conditioning chambers. Following 3 days of a 'washout' period from the sub-chronic treatment, groups of rats (n=12) were given access to nicotine in 1hr sessions under a fixed-ratio schedule of reinforcement. Both ketamine- and vehicle-treated subjects showed a steady rate of acquisition with no significant difference between the groups. There was a tendency for ketamine-treated rats to self-administer fewer nicotine injections which was reflected in the dose-response curves generated under a fixed-ratio of 3. Similarly, under a progressive ratio, no significant difference between the groups was apparent. Saline substitution extinguished responding in both groups but with no overall difference between the groups. The results from this experiment suggest that the sub-chronic regimen of ketamine treatment used to model cognitive deficits associated with schizophrenia in rats does not extend to the increased intake of nicotine in the self-administration model. Moreover, the findings suggest that the reinforcing effects of nicotine are not enhanced by ketamine and thus highlight a therapeutic role for nicotine in tobacco that serves to enhance cognition in patients with schizophrenia.

Title: Extinction of cocaine-seeking with cocaine methiodide attenuates priming-induced but not footshock-induced reinstatement of cocaine-seeking

Authors: S. MYAL, B. WANG, *R. A. WISE
NIDA IRP, BALTIMORE, MD

Abstract: Cocaine hydrochloride (cocaine HCl) is habit-forming because of its ability to elevate extracellular dopamine levels in the brain. Cocaine methiodide (MI), a charged analog of cocaine that does not cross the blood-brain barrier, is not rewarding in its own right, but acquires conditioned rewarding properties when animals learn_through repeated experience with intravenous injections of cocaine HCl_that the rewarding central effects effects are predicted by the more immediate peripheral actions of the drug. The peripheral actions come to trigger the release of glutamate in the ventral tegmental area in cocaine HCl-trained but not cocaine HCl-naïve animals. The peripheral cocaine effects_triggered experimentally by cocaine MI_lose their

reinforcing efficacy as they are repeatedly experienced without the subsequent central effects that are experienced with cocaine HCl. Here we examined extinction of cocaine seeking when cocaine MI or saline were substituted for cocaine HCl, and we determined the abilities of footshock or experimenter-administered cocaine to reinstate cocaine-seeking following extinction with cocaine MI or saline. On the first day of extinction testing, responding was attenuated more with saline than with cocaine MI substitution; however, after the first day, extinction proceeded about equally with the two substitutions. Although footshock reinstated cocaine seeking equally in cocaine MI-extinguished and saline-extinguished animals, drug-primed reinstatements with cocaine HCl-induced and cocaine MI-induced reinstatements were much weaker in cocaine MI-extinguished animals. Thus breaking down the learned association between the peripheral and central effects of cocaine may be useful to reduce cocaine craving in users who lapse.

Abstract: We previously reported that, in the novel paradigm, 8-arm food foraging task (8-arm FFT) that limited the quantity of rewards and had a longer period of the reward-unavailable situation after acquisition of the last reward, animals expected no available reward resulting from their own reward acquisition behavior and inhibited redundant actions. Moreover we suggested that the nucleus accumbens core (AcbC) was necessary for inhibition of redundant activity based on the expectation of 'no-reward' during learned reward-unavailable situation. In the present study we examined how accumbens core and shell (AcbS) were involved in the inhibition of behavioral activity. The AcbC- or AcbS-lesioned rats trained by the 8-arm FFT showed higher activity during 10 min after last-reward-acquisition than intact rats, suggesting that both AcbC and AcbS inhibit activity after last-reward-acquisition. We compared the temporal change of

activity after last-reward-acquisition in three groups. AcbC-lesioned rats showed higher activity during 2 min after last-reward-acquisition, and same level of activity during 6-10 min compared to intact rats. Although AcbS-lesioned rats showed no significant effects on behavioral activity during 2 min after last-reward-acquisition, they showed higher activity during 2-10 min after last-reward-acquisition compared to intact rats. These results suggest that, AcbC and AcbS are involved in the inhibition of redundant activity during learned reward-unavailable situation with different temporal patterns.

Title: Cytochrome oxidase metabolic mapping of cocaine sensitized rats

Authors: *M. E. VELEZ[1], E. PADILLA[2], F. GONZALEZ-LIMA[2], C. A. JIMENEZ-RIVERA[1]
[1]Physiol., UPR-RCM, San Juan, PR; [2]Univ. of Texas, Austin, TX

Abstract: Addiction has been considered an aberrant form of learning that incorporates synaptic plasticity. When changes in neuronal activity occur throughout the brain, the energy demands of a cell also fluctuate. Cytochrome oxidase (CO) is a mitochondrial membrane protein that helps supply energy demand by generating ATP via oxidative phosphorilation. Here we wish to characterize which neural systems modify their CO activity as a result of cocaine sensitization. Rats were injected with 15mg/kg cocaine i.p. or isovolumic saline for five days. One hour after last injection brains were removed and slices were stained for CO activity. Subjects injected with cocaine had developed a strong sensitized response measured by an increased locomotor activity (5828 ± 433 pcc) when compared to day one (3062 ± 599 pcc). CO activity was significantly decreased in cocaine-treated animals in the superficial layers of the dorsal and lateral frontal cortex regions (DFS = 217 ± 8 and LFS = 242 ± 9) when compared to saline-treated animals (DFS = 244 ± 8 and LFS = 265 ± 6). Inter-regional correlations of CO activity showed that noradrenergic paths between the locus coeruleus and deep layers of the infralimbic cortex were positively correlated in animals treated with cocaine (r = 0.802) but not in control rats. In

dopaminergic pathways, significant positive correlations were observed between the substantia nigra compacta and the superficial layer of the medial frontal cortex (r =0.809), the deep layer of the lateral frontal cortex (r=0.770) and the superficial layer of the lateral orbital cortex (r=0.717) only in cocaine treated animals. In cholinergic pathways, CO activity in the interpeduncular nucleus was negatively correlated with the activities of the deep layer of the dorsal frontal cortex (r = -0.851), the superficial and deep layers of the anterior insular cortex (AIS, r = -0.672 and AID, r = -0.954), the superficial and deep layers of the lateral orbital cortex (LOS, r = -0.697 and LOD, r = 0.847) in saline treated animals but not in rats that received cocaine. Taken together our data suggest that prefrontal networks change from inhibitory cholinergic influences to networks driven by noradrenergic and dopaminergic pathways after cocaine exposure. Cocaine sensitization to cocaine may release behaviors that normally are inhibited by the prefrontal cortex. When prefrontal networks for inhibitory control are impaired, impulsive behaviors may arise.

Title: Consumption of highly palatable foods and nociceptive sensitivity in free-feeding adult male mice

Authors: *C. M. TENK[1], R. N. KIMANI-DUPUIS[1], M. KAVALIERS[2]
[1]Psychology, Brescia Univ. Col., London, ON, Canada; [2]Psychology & Grad. Program in Neurosci., Univ. of Western Ontario, London, ON, Canada

Abstract: Highly palatable foods, such as those high in sugars, fats or both, are highly preferred both by humans and rodents. These foods act as natural rewards and activate endogenous dopamine and opioid systems. These systems play an integral role in pain modulation with results of prior research having shown that palatable foods affect nociceptive and pain sensitivity. Consumption of fats has been reported to decrease pain/nociceptive sensitivity while

consumption of sugars either increases or decreases pain/nociceptive sensitivity depending on both the duration of ingestion as well as the time period between ingestion and presentation of the noxious stimulus. The current study with mice examined the consumption of highly palatable foods (sugar-fat or sugar) during repeated, limited access feeding and the subsequent effect on nociceptive sensitivity. For four consecutive days, nociceptive responses (latency of a foot lift/lick response to a 50 C surface) in free-feeding CD-1 male mice (n=8 per group) were assessed before, and after, 1hr access to one of four foods (sugar, sugar-fat, lab-chow, no food). Locomotor activity was also assessed during the feeding period using an automated open-field. Animals fed sugar-fat consumed significantly more than all other groups during the feeding period. In addition, the patterns of consumption significantly differed among groups with the sugar-fat animals, despite consuming significantly more food, making significantly fewer entries into, and spending significantly less time in, the food dish area than other groups. Furthermore, consumption of both palatable foods, sugar and sugar-fat, significantly decreased paw lick latency relative to chow and no-food controls, indicating an increase in nociceptive sensitivity (hyperalgesia) in these groups. These results indicate that a highly palatable sugar-fat food is readily consumed by adult male mice but the patterns of consumption are significantly different than those for sugar. However, despite these differences in consumption, these data suggest that sugar-fat ingestion influences nociceptive sensitivity in the same manner as sugar, increasing nociceptive sensitivity and inducing hyperalgesia in this experimental model.

Title: A selective role for lmo4 in cue-reward learning.

Authors: *R. MAIYA[1], U. HEBERLEIN[2,1]
[1]Ernest Gallo Clin. and Res. Ctr., Emeryville, CA; [2]Dept. of Anat., Univ. of California, San Francisco, San Francisco, CA

Abstract: Cues associated with drug seeking play an important role in initiating drug craving and seeking in abstinent addicts. Hence, understanding the molecular mechanisms that underlie the formation of cue-reward associations may have important implications for the treatment of

addictive disorders. We have previously demonstrated a role for the transcriptional regulator *Lmo4*, which is highly expressed in pyramidal projection neurons of the basolateral complex of the amygdala (BLC) in fear learning. The BLC has also been shown to modulate selective aspects of cue-reward learning. Hence, in this study we sought to examine the role of *Lmo4* in the formation of cue-reward associations and the subsequent ability of such reward-paired cues to control goal-directed behavior. We first examined cue-reward learning in mice heterozygous for a genetrap insertion at the *Lmo4* locus, which results in 50% reduction in *Lmo4* levels. Both wild type (WT) and *Lmo4gt/+* mice readily learned to associate the presentation of stimuli with the delivery of an appetitive reinforcer. Furthermore, reward-paired cues were able to elicit approach behavior in the absence of the primary reinforcer (goal tracking) equivalently in both genotypes. We next examined conditioned reinforcement, which is a measure of the motivational properties of the reward-paired cue, in both genotypes. Interestingly, our results suggest that reward-paired cues served as conditioned reinforcers in WT but not *Lmo4gt/+* mice, suggesting a deficit in assigning incentive value to the cue in *Lmo4gt/+* mice. Since the BLC along with several forebrain regions plays a critical role in attributing incentive value to the cue, we examined the effects of knockdown of *Lmo4* specifically in the BLC on conditioned reinforcement. Preliminary results suggest that shRNA-mediated knockdown of *Lmo4* expression in the BLC, also results in a selective deficit in conditioned reinforcement. In summary, these results suggest a novel and selective role for the transcriptional regulator *Lmo4* in the BLC in attributing incentive salience to conditioned cues.

Title: Basolateral amygdala mediation of palatable diet consumption driven by intra-accumbens DAMGO administration and 24-hour food deprivation: A behavioral and neural activation examination

Authors: *K. PARKER, M. P. MCCABE, F. ODU, R. SHARMA, M. M. THAKKAR, M. J. WILL
Univ. Missouri, Columbia, MO

Abstract: The amygdala has been of considerable interest in learning, motivation, reward, and addiction research, but a recent surge of reward and feeding research has raised awareness of the potential role of the amygdala in the overconsumption of palatable foods. Administration of μ-opioid receptor agonists into the nucleus accumbens or 24-hour food deprivation increases consumption of a palatable, high-fat diet. Studies from our laboratory have suggested an important role of the basolateral amygdala (BLA) in mediating the feeding behavior following intra-accumbens DAMGO administration. Blocking neural activity within the basolateral amygdala via GABAA agonist muscimol has been shown to block the feeding following intra-accumbens administration of DAMGO (Will et al., 2004). Although muscimol inactivation of the BLA reduced DAMGO-induced food intake to control levels, this treatment led to exaggerated number and duration of food hopper entries after food intake had ended (Will et al., 2009). A subsequent experiment under conditions of limited access to the diet (8 grams) found the identical pattern of exaggerated hopper entries and duration following intra-Acb administration of DAMGO, regardless of whether the BLA was inactivated. Additionally, BLA muscimol inactivation had no influence on feeding driven by 24-hour food deprivation, suggesting the BLA selectively influences DAMGO-induced feeding. The present experiments were conducted to replicate these behavioral findings in rats that were immediately sacrificed following the feeding session to assess patterns of neural activity in key feeding related brain regions. Therefore, c-Fos double-labeling fluorescent immunohistochemistry was conducted on tissue from multiple brain areas shown to contribute to feeding behavior, including the orbital frontal cortex, nucleus accumbens, ventral pallidum, hypothalamus, amygdala, and ventral tegmental area.

Title: Long-term consequences of sweet solution consumption in rats.

Authors: G. SENTHINATHAN, A. CELEJEWSKI, *R. EIKELBOOM
Wilfrid Laurier Univ., Waterloo, ON, Canada

Abstract: Access conditions may have profound effects on consumption, beyond those driven by need. Restricted access models can be used to control and manipulate consumption of natural rewards and drugs. Non-food deprived rats consume excessive amounts of 4% sucrose solution when daily access is restricted to 24h out of every 72 or 96h, but consume much smaller amounts when given 24h ad libitum (AL) access (Hewitt & Eikelboom, 2008). When all rats are subsequently given alternate day access, rats from the restricted group continue to show significantly higher consumption. It is unclear if a) the consumption difference will be maintained with an extended alternate day access period and b) if the consumption difference is due to elevated intake induced by restricted access or if a period of AL access prevents rats from increasing intake. The present study investigates these questions, examining the longer-term consequences of sweet solutions consumption.
Sprague-Dawley rats (~ 65 days old) were randomly assigned to AL or restricted (once every third or fourth day) access to 0.25% saccharin (Exp. 1) or 4% sucrose (Exp. 2) until consumption stabilized and in Exp. 3 access to AL sucrose or no sucrose (NS). Subsequently all rats in Exp. 1 received alternate day access to saccharin for an extended period. In Experiments 2 and 3 following stabilization of sucrose consumption, groups were split and rats received either AL or restricted (once every 3 days) access to sucrose.
With an extended alternate day access period (Exp. 1) the saccharin consumption difference was maintained for over 45 days. AL rats switched to restricted access (Exp. 3) immediately increased intake, matching control NS restricted access rats. In Exp. 2 restricted rats showed double the consumption of AL rats, restricted access rats continued to consume high levels of sucrose solution when switched to AL access. After about 30 days of AL access the consumption was similar to chronic AL rats. Ad lib access to sucrose does not prevent rats from developing high consumption when access conditions are suddenly restricted. The elevated intake caused by a period of restricted access is robust and resistant to change but eventually returns to lower levels of consumption with ad lib access.

Title: Adolescent oxycodone self-administration enhances subsequent oxycodone-induced conditioned place preference and locomotor activity in C57BL/6J mice

Authors: *Y. ZHANG[1], A. HO[2], M. KREEK[2]
[1]Rockefeller Univ., NEW YORK, NY; [2]The Lab. of the Biol. of the Addictive Dis., The Rockefeller Universtiy, New York, NY

Abstract: Illicit use of opioid analgesics (e.g., oxycodone) in adolescence is a rising problem in the United States. *Objective:* Our goal was to determine whether adolescent oxycodone self-administration affects subsequent oxycodone-induced conditioned place preference (CPP) and locomotor activity in mice. *Methods:* Groups of adolescent C57BL/6J mice (4 weeks old) underwent surgery during which a catheter was implanted into their jugular veins. Mice were given five days to recover from the surgery and were placed in the self-administration chambers for acquisition of oxycodone self administration. Mice self administered oxycodone (0.25mg/kg/infusion) 2 hrs daily for 14 days while controls received yoked saline administration. Fifteen days after the last oxycodone self-administration session, mice underwent a 10-day oxycodone CPP training procedure (1, 3, 10, mg/kg, i.p., separate groups). *Results:* Mice that had self-administered oxycodone during adolescence spent more time in the oxycodone-paired chamber ($p < 0.05$ and $p < 0.01$ for 1 and 3 mg/kg CPP groups, respectively) than those that were oxycodone-naïve (yoked saline controls). Further, oxycodone increased locomotor activity significantly more in mice that had self-administered oxycodone than the yoked saline control ($p < 0.05$). *Conclusion:* Adolescent oxycodone self-administration increased the rewarding effect of oxycodone upon re-exposure to oxycodone.

Title: Is reward system involved in pair bonding in ring doves?

Authors: A. DIOS[1], K. ALEXANDER[2], S. J. HANSON[2], *M.-F. CHENG[2]
[1]Psychology, [2]Rutgers Univ., NEWARK, NJ

Abstract: Although the term “pair bonding” is used freely in academic literature, much is not known about how it is characterized. Previous work done in our lab suggests that pair bonded ring doves, operationally defined as doves that have completed a breeding cycle and successfully reared a squab (Erickson 1971), prefer to spend time with their mates during behavioral preference tests. These tests, however, are subject to environmental factors, such as housing conditions and testing parameters, that can diminish their sensitivity as a predictor of pair bonding. Because of these testing constraints, our lab sought to find a neural marker that would be a better predictor for pair bonding. Our present study examines whether ZENK expression in the nucleus taeniae (avian amygdala) serves as a predictor for pair bonding in female ring doves. We found that we were able to predict pair bonding using a quadratic discriminant analysis on principal component scores conducted on ZENK cell counts in the nucleus taeniae. Additionally, we found there are no gender differences in the prediction of pair bonding. This method appears to be more sensitive in predicting pair bonding than behavioral preference tests. Previous tract tracing studies in our laboratory suggest that regions involved in the reward system circuitry, including the nucleus accumbens and hypothalamatic regions, project to the nucleus taeniae. Lesion studies will be done to determine if the nucleus taeniae and these regions contribute to pair bonding behavior.

Title: Involvement of the basolateral amygdala in homeostatic and hedonic feeding on a progressive-ratio breakpoint task

Authors: H. W. JOHNS, *D. K. MILLER, K. E. PARKER, A. S. SAGE, M. J. WILL
Psychological Sci., Univ. of Missouri, COLUMBIA, MO

Abstract: The amygdala has been long recognized as an important structure for motivation, emotion, and learning. Integral to motivational and appetitive systems, the basolateral nucleus of the amygdala (BLA) monitors and updates changes in a stimulus' incentive value, and,

consequently, mediates goal-directed behavior. One important afferent of the BLA is the nucleus accumbens (Acb). Stimulation by the synthetic opioid DAMGO of the nucleus accumbens of the ventral striatum has been shown to robustly increase intake of palatable food (e.g., fat, sugar, and salt); however, this process is dependent upon the BLA. Pharmacological inactivation of the BLA via infusion of GABAA agonist muscimol abolishes palatability-driven feeding, but not homeostatic feeding.
Our lab uses a rat model to study the neural mechanisms of both motivational states (ie, palatability- versus homeostatic-driven feeding). Previous work from our lab in a free-feeding experiment has demonstrated that rats pre-treated with BLA muscimol and Acb DAMGO tend to approach, but not consume, a high-fat chow at a significantly greater rate than those receiving either drug in isolation. These data suggest that the approach and consummatory phases of feeding are dissociable. To more closely study these phases of feeding in the aforementioned motivational states, we have established a dose of DAMGO that produces operant lever-pressing behavior for sucrose pellets equivalent to that of 24-hour food deprivation. We will next investigate the role of the BLA in producing lever-pressing behavior in two separate experiments. The first will measure lever-pressing breakpoint and possible place conditioning behavior as mediated by several doses of Acb DAMGO and BLA muscimol (DAMGO dose: saline, .025, .25 micrograms/.5 microliter; muscimol dose: saline, 20 nanograms); the second will measure the same variables using BLA muscimol and food deprivation (0, 24, 48 hours deprived) instead of DAMGO infusion.

Title: Nucleus accumbens deep brain stimulation in a rat model of binge eating

Authors: *W. DOUCETTE, J. MACLEOD, J. LEITER, A. GREEN
Dartmouth Hitchcock Med. Ctr., Lebanon, NH

Abstract: Binge eating disorder affects 0.7-4% of the general population, and bingeing behavior is present in 30% of dieting obese individuals. Binge eating is defined as repeated, discrete, and intermittent bouts of consuming unusually large amounts of food. Those with binge eating

disorder have binges that are calorically dominated by sugar and fats and often consist of foods such as ice cream and cake - foods that have been shown to be potent activators of the brain reward circuit. Work of others has demonstrated that a restricted sweet-fat diet in rats can produce binge eating behavior. We have used this rat model to test the hypothesis that treatment with deep brain stimulation in the nucleus accumbens (NAc), a crucial component in the brain reward circuit, will decrease the percentage of total calories consumed during restricted access to the sweet-fat diet. This hypothesis is based on the following: 1) brain areas thought to be dysfunctional in both addiction and eating disorders include the NAc; and 2) deep brain stimulation in the NAc has been shown to decrease alcohol use in animal models of addiction. Sprague-Dawley rats were given restricted access (2 hours/day, from 6 to 8 hr after the onset of the dark cycle) to a highly palatable sweet-fat chow (*Teklan diets*), with standard chow provided *ad libitum,* and daily measurements of consumption of each type of food, water and body weight. Following insertion of electrodes into the NAc animals were exposed to this feeding paradigm until binging was stable from day to day. A *Grass* stimulator with an optical isolation unit delivered high frequency (150 Hz), constant current (0.2 mA), bilateral monophasic stimulation with a pulse duration of 60 µsec during the restricted access phase in the treatment group and was compared to an implanted sham stimulation group. Pilot data collected to date demonstrate a statistically significant ($p < 0.0005$) 30% reduction in caloric intake during the binge period in the active stimulation group compared to the sham control group. Statistical analysis of the two groups was performed using an ANOVA with a post-hoc Tukey test. Preliminary data suggest that deep brain stimulation within the NAc can decrease caloric intake during the binge eating period in an animal model of binge eating disorder. While this study only addresses stimulation to reduce bingeing, future work will be needed to determine if chronic stimulation can not only reduce bingeing but also produce sustained weight loss.

Title: Microstructural studies of the ingestive behavior evoked from the nucleus accumbens shell and ventral palllidum

Authors: *I. RIVERO-COVELO, I. SALIJA, D. WIRTSHAFTER, T. R. STRATFORD
Psychology, Univ. Illinois Chicago, CHICAGO, IL

Abstract: Dramatic increases in the intakes of solid and liquid diets can be produced by injections of the GABA-A agonist muscimol into the nucleus accumbens shell (AcbSh). Similar effects are seen after injections of the GABA-A antagonist bicuculline into the medial ventral pallidum (VPm), a structure which receives GABAergic projections from the AcbSh.
Alterations in food intake can result from a number of different types of behavioral changes. In order to determine how behavior is altered by manipulations of the AcbSh and the VPm, it is necessary to actually examine the animals' behavior, rather than relying on measurements of intake. In these experiments, we used microstructural techniques to determine exactly how licking behavior is altered by drug injections in the AcbSh or VPm.
Injections of muscimol into the AcbSh of rats consuming a 10% sucrose solution led to large increases in total consumption and in the number of licks emitted, without altering mean lick volume. Rats normally emit licks in "clusters", which we define as strings of licks separated from each other by interlick intervals (ILIs) of more than 0.5 sec. Increases in intake could thus result either from increases in the mean size of clusters (SC) or in the total number of clusters emitted (NC). We found that effects of intra-AcbSh muscimol were entirely due to increases in NC, with no change in SC. The "within burst lick rate," i.e. the mean value of ILIs less than 0.25 sec, was unaffected. When examined across time (t), licking behavior can be well described by the exponential decay equation "cumulative licks = ab(1-exp(-t/b))", where the "a" parameter reflects the initial rate of licking, and "b" is the decay constant. Nonlinear curve fits indicated that the effects of intra-AcbSh muscimol were due entirely to increases in the time constant, with no alterations in initial rate.
In animals receiving bicuculline in the VPm, increases in licking again resulted entirely from increases in the number of clusters and in the time constant "b" of the exponential curve fits. In this case both cluster size and the rate constant "a" were significantly reduced, although these changes were not large enough to offset the effects on NC and "b".
These results indicate that there are both similarities and differences between the hyperphagia syndromes induced from the AcbSh and VPm. Many studies have suggested that changes in dietary palatability are associated with alterations in SC and "a". The current findings provide no support for the view that effects of muscimol in the AcbSh are mediated through changes in palatability, and raise the possibility that the effects of bicuculline in the VPm may occur in spite of a reduction in palatability.

Title: Using genetic tools to examine ventral hippocampal mediated exploration

Authors: *R. NGUYEN[1], V. MAHADEVAN[2], B. RICHARDS[3], M. WOODIN[2], J. S. YEOMANS[1], J. C. KIM[1]
[1]Psychology, [2]Cell and Systems Biol., [3]Physiol., Univ. of Toronto, Toronto, ON, Canada

Abstract: Chemical and electrical stimulation of the ventral hippocampal formation (vHPC) activates dopamine release in the nucleus accumbens and increases locomotion in rats. We extended these findings in mice using optogenetic and pharmacogenetic tools delivered by adeno-associated virus. Open field locomotion was examined upon light-stimulation of channelrhodopsin-2, or clozapine-N-oxide (CNO) stimulation of the hM3D receptor in the vHPC. Both methods of activation significantly increased spontaneous locomotion. Furthermore, activation of the hM3D receptor with CNO increased the firing rate of CA1 pyramidal neurons recorded in vitro. Our findings suggest that genetically induced vHPC activity enhances locomotion in mice. Additionally, retrograde tracing from the nucleus accumbens shell and medial prefrontal cortex (mPFC) resulted in cell body labeling in the ventral CA1 and subiculum. Therefore, we investigated the locomotor effect of silencing the mPFC while stimulating the vHPC. Genetic methods will help define the specific neural populations in vHPC and mPFC modulating dopamine system function.

Title: Prepronociceptin polymorphisms predict inter-individual variability in placebo-induced opioid release

Authors: *M. SIKORA, M. PECINA, E. AVERY, V. DIAZ, J.-K. ZUBIETA
Univ. of Michigan, Ann Arbor, MI

Abstract: The neuropeptide nociceptin, also called orphanin FQ (N/OFQ), is the endogenous agonist of the N/OFQ peptide receptor (NOP receptor). Both N/OFQ and the NOP receptor share a high degree of homology with classical opioid peptides and opioid receptors, respectively, and use similar signal transduction pathways. Among many biological roles suggested for the N/OFQ/NOP receptor system, modulation of opioid analgesia has been most widely investigated and this system has been reported to counteract several opioid-mediated effects. The N/OFQ/NOP receptor system is present in vlPAG neurons, where there is also a high density of opioid peptides and receptors. N/OFQ microinjection in the vlPAG antagonizes the acute antinociceptive effects of DAMGO and morphine. Here we hypothesized that genetic variation within the precursor prepronociception will influence placebo response and the Δ u-opioid BPND associated to it.

Title: Molecular level functional MRI of dopamine release in the ventral striatum

Authors: *T. LEE, L. CAI, A. JASANOFF
Bio-engineering, M.I.T., CAMBRIDGE, MA

Abstract: Dopamine signaling is critical to brain systems controlling voluntary movement, learning, and the experience of reward. Although extensive studies of dopaminergic neural activity have been performed using electrophysiology and pharmacological approaches, very little information has been obtained about spatial characteristics of dopamine signaling in the brain. To address this issue, we recently developed a family of protein-based contrast agents that can detect dopamine in magnetic resonance imaging (MRI). Here we use these probes to perform molecular-level functional imaging of dopamine release during delivery of a widely-studied artificial reward, electrical stimulation of the medial forebrain bundle (MFB) in rats.
Rats were implanted with electrodes targeted to the MFB, and operant responses to MFB stimulation were verified behaviorally. Animals were then anesthetized, tracheostomized, artificially ventilated, and injected with 80 mg/kg L-DOPA in preparation for dopamine imaging. They were placed in a cross coil system and inserted into a 9.4 T Bruker Avance II MRI scanner. During imaging with gradient echo T1-weighted contrast (TR/TE = 250/10 ms), the dopamine sensor BM3h-9D7 was infused into brain (0.1 μL/min.) in order to fill large regions of the ventral striatum. Following 50 minutes of infusion, MFB stimuli (2 ms pulses, 60 Hz, 250 μA) were delivered in blocks of 16 s, alternating with 300 s epochs of rest. Statistical analysis using AFNI revealed significant stimulation-associated MRI signal changes across the ventral striatum, with the strongest responses observed in the medial part of nucleus accumbens shell. Average time series data indicated signal changes of up to 2%, consistent with peak dopamine concentrations of approximately 10 μM binding to the sensor. These responses varied in a manner dependent on the stimulus parameters, and were not observed using an inactive form of the MRI sensor, WT BM3h. Parallel measurements using electrochemical detection verified that dopamine concentrations determined by MRI were realistic, and confirmed that BM3h-9D7 binds dopamine in vivo.
These experiments offer a novel and qualitatively unique spatiotemporal view of phasic dopamine signaling, and provide direct evidence for the spatial heterogeneity of dopamine release in the ventral striatum.

Title: Is risk-taking behaviour mediated by imprinted genes?

Authors: C. L. DENT[1], A. WARD[2], A. PLAGGE[3], J. WILKINS[4], *T. HUMBY[1], A. R. ISLES[1]
[1]Sch. of Psychology, Cardiff Univ., Cardiff, United Kingdom; [2]Univ. of Bath, Bath, United Kingdom; [3]Sch. of Biomed. Sci., Univ. of Liverpool, Liverpool, United Kingdom; [4]Santa Fe Inst., Santa Fe, NM

Abstract: Impulsivity and risk taking are natural parts of human behaviour, however it seems that in certain individuals, these behaviours become pathological and maladaptive. Increased impulsivity and risk-taking are recognised as clinical traits of many psychiatric disorders, including schizophrenia and attention deficit/hyperactivity disorder (ADHD), as well as drug addiction and gambling. A prominent feature of impulsive choice is an intolerance of a delay of a reward or gratification. One method used to target the measurement of this behaviour is the 'delayed-reinforcement task' (DRT). By employing the use of mouse models with genetic knock-outs, we have discovered that impulsive and risk-taking behaviours are mediated by epigenetic factors, and specifically by brain-expressed imprinted genes.
Imprinted genes, defined by their parent-of-origin specific monoallelic expression, have been shown to have an increasingly important role in mediating adult behaviour1. Using separate strains of mice with genetic deletions of the genes Nesp55 and Grb10, oppositely imprinted in the adult brain, DRT performance was assessed. Maternally expressed Nesp55 promoted the riskier choice of larger delayed rewards, whereas paternally expressed Grb10 reduced the choice of larger delayed rewards. This indicates that maternal genomes can contribute differentially, and perhaps, antagonistically, to impulsive and risk-taking behaviour.
To explore this effect further, we are developing a novel test of risk-taking behaviour. The 'predator odour risk-taking task' uses a predator odour as a fear stimulus, to induce a conflict with obtaining a reward. Mice were trained to cross the central chamber of a three-chambered apparatus to collect a liquid reward. It was observed that when a predator odour (rat, cat, fox) was present in the middle chamber, mice took significantly longer to cross the apparatus to collect the reward; suggesting that the presence of a predator odour successfully induced fear, and therefore provided an index of risk-taking behaviour. This behaviour is being further explored using pharmacological manipulation, specifically taxing the dopaminergic, serotoninergic and noradrenergic systems, in order to examine the role that these neurotransmitter systems may have upon risk-taking behaviour in this task. We will then

examine the behaviour of Nesp55 and Grb10 KO mice in this task, which will not only provide a novel measure of their risk-taking behaviour, but will also help define the specific mechanism that Grb10 and Nesp55 have on risk-taking behaviour.

Title: Single neuronal encoding of reward uncertainty in the frontal midline structures of the monkey

Authors: *I. E. MONOSOV, O. HIKOSAKA
NEI/NIH, Bethesda, MD

Abstract: Uncertainty about the future modulates decision-making, motivation, and emotion. This suggests that the brain may convert outcome-distributions used for valuation to degrees of uncertainty. The ventral portion of the anterior midline of the primate brain, including ventromedial prefrontal cortex (vmPFC) and septum, is thought to play a role in processing information about reward and modulating emotional states. But if and how single neurons there are modulated by uncertainty about rewards and punishments is unknown. While four monkeys were presented visual cues associated with different probabilities of rewards and punishments, we recorded from single neurons over a wide area of the anterior ventral midline, including the vmPFC (primarily in areas 25 and 14), septum, and the anterior hippocampal continuation (AHCC) (i.e., the area dorsal to the vmPFC and septum). We found that neurons in the AHCC responded strongly to cues predicting upcoming rewards probabilistically (i.e., 50%, 25%, 75%), but showed little response to cues predicting upcoming rewards certainly (0%, 100%). In contrast, they were not influenced by uncertainty about punishments. When a different set of cues was used to predict different amounts of reward, AHCC neurons showed little response to any of the cues. Based on our findings, we hypothesize that AHCC promotes learning and enhances vigilance in an uncertain environment. We also found that neurons in ventral vmPFC were influenced by reward-uncertainty in a manner analogous to hope: they responded similarly to cues predicting reward delivery certainly (100%) and to cues predicting rewards

probabilistically (50%). In summary, AHCC signals the degrees of reward-uncertainty, whereas ventral vmPFC signals the possibility of obtaining reward. Both schemes may play important roles in motivatated behavior in uncertain environments.

Title: Intracranial self-stimulation as the positive reinforcer to study impulsivity in a delayed discounting paradigm in rats

Authors: *S. TEDFORD[1], A. PERSONS[1], L. CHEN[1], S. L. ROKOSIK[1,2], T. C. NAPIER[1]
[1]Dept. of Pharm., and Ctr. for Compulsive Behavior and Addiction, RUSH Univ., Chicago, IL; [2]Neurosci. Program, Loyola Univ. Chicago Med. Ctr., Maywood, IL

Abstract: Alterations in impulsivity are associated with drug and behavioral addictions. Delayed discounting is an established method used to assess impulsive choice in both humans and rodents. Impulsive choice is reflected in the selection of a small, immediate reward over a larger, delayed reward. To test impulsive choice in rats, food is often used as the positive reinforcer which poses potential confounding factors including the need to food deprive animals and subsequent satiation. To model mechanisms that underlie the many facets of impulsivity, a common universal reinforcing property is needed. A realistic alternative to food reward is intracranial self-stimulation (ICSS). ICSS directly targets a common reward system that is activated regardless of modality. We recently implemented a rodent model of ICSS-mediated probability discounting (Rokosik and Napier, JNeurosci Methods, 198:260, 2011; Rokosik and Napier, NPP, 37:1397,2012). Here, we tested the hypothesis that ICSS can provide a positive reinforcer for delayed discounting tasks. Rats were implanted with bipolar stimulating electrodes targeted at the lateral hypothalamus (LH), and after recovery, they were trained to associate the positively reinforcing electrical stimulation of the LH with a lever press with a forepaw.

Stimulation of 50Hz and 160Hz were used for the small and large reinforcer, respectively. Our prior work demonstrated that these values elicited near EC50 and Emax levels of responding with no aversive effects. Rats were trained in a Choice Test that determined their ability to discriminate between the small and large reinforcers. The task was successfully acquired within one week, and then rats entered the delayed discounting task. Several delays were tested. Data collected thus far have shown that with a three sec delay, rats prefer the large reinforcer (by ~80%) over the small, immediate reinforcer. By 15 sec, the rats consistently switch to the small, immediate reinforcer. These data indicate that an ICSS-mediated delayed discounting paradigm is feasible and a streamlined alternative to food reward studies.

Title: Adolescent risk taking and resting state functional connectivity.

Authors: S. J. DEWITT[1], S. ASLAN[2], N. CHUKWUEKE[3], V. GERMER[3], *F. FILBEY[4]
[1]Brain and Behavioral Sci., Univ. of Texas at Dallas, Dallas, TX; [2]AdvanceMRI, LLC., Frisco, TX; [3]Ctr. for BrainHealth, Dallas, TX; [4]Univ. of Texas At Dallas, Dallas, TX

Abstract: Funding Support: Center for BrainHealth Seed Grant
Resting state functional connectivity (rsFC) allows the assessment of intrinsic network connectivity of brain areas in the absence of specified goal-directed behaviors. In the present study, we examined how circuits that include the amygdala, a region of emotion processing, may distinguish risk-taking from non-risk-taking youth. Resting fMRI data were collected in 25 risk-taking (risky) and 18 non-risk-taking (control) youth as measured by the Youth Risk Behavior Scale(YRBS). We hypothesized that there would be disruptions in rsFC between the amygdala and prefrontal control areas, such as the anterior cingulate in the risk group compared to the control group. Furthermore, we hypothesized that the rsFC (i.e. z-scores) will correlate with temperament and impulsivity as measured by the Junior Temperament Childhood Inventory (JTCI) score and the Impulsive and Sensation Seeking Scale (IMPSS), respectively. Voxel-based-analysis of z-score functional maps (seed region: amygdala) revealed greater connectivity

with the left cingulate gyrus, bilateral precuneus, right middle frontal gyrus and supramarginal gyrus at cluster threshold of K≥ 17 and $p \leq 0.001$(using AFNI). Analysis of behavioral data revealed significantly higher scores on the IMPSS for the risky group vs. controls, t(41) = 2.23 p =0.03, but IMPSS did not correlate with amgydalar connectivity in either group . A significant negative correlation was found between amygdala-right middle frontal gyrus coupling and the reward dependence subscale of the JTCI for controls (r = -.58 p = 0.01), such that the greater the reward-driven emotionality, the weaker the connectivity between amygdala-PFC. There were no significant correlations found in the risky group. Enhanced rsFC in the risky group between amygdala and posterior cingulate gyrus, and right precuneus has been postulated to underlie intense automatic emotional reactivity (Pavuluri et al. 2009). Similar enhanced connectivity between amygdala and PFC regions in high-risk youth (i.e., adolescents with family history of substance abuse) (Silveri et al., 2011) suggests that this pattern could be a biomarker for addiction. To conclude, these findings suggest systems-level disruptions in risk-taking youth that are not present in non-risk taking youth. These findings could inform treatment development for at-risk youth.

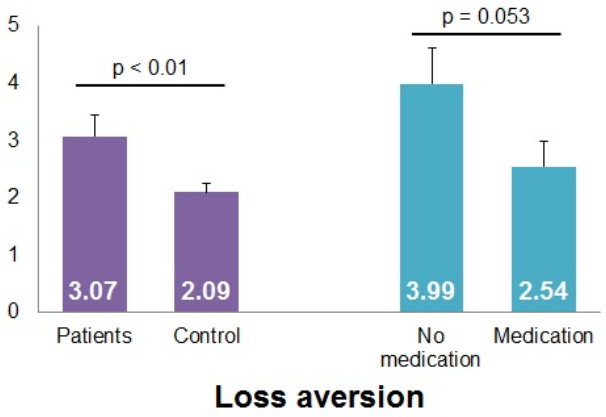
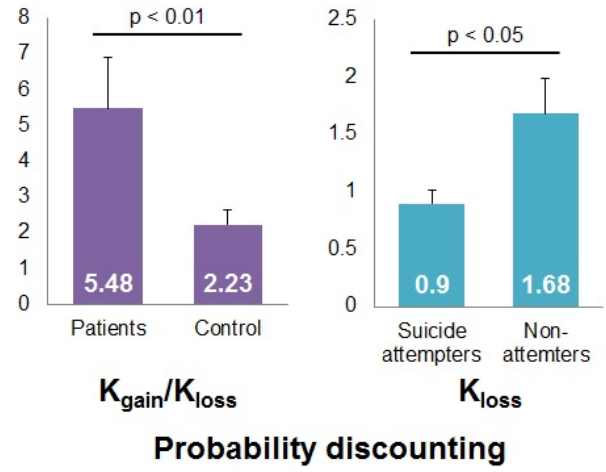
Title: Impaired risky decision making in depressed patients with and without suicide attempt history

Authors: *K. BAEK[1], J.-H. KWON[1], J.-H. CHAE[2], J.-A. MIN[2], K. CHOI[2], K. JANG[2], N.-B. LEE[2], J. JEONG[1]
[1]Bio and Brain Engin., KAIST, Daejeon, Korea, Republic of; [2]Dept. of Psychiatry, Col. of Med., The Catholic Univ. of Korea, Seoul, Korea, Republic of



Abstract: Depression is depressive mood state characterized by negative bias in cognition, and often results in impairment in decision making. Suicide attempts might be viewed as a non-optimal decision making process. Decision making tasks such as Iowa gambling task has been used in experimental studies with depressed patients and suicide attempters, but the deficit in



decision making was still not well clarified. We hypothesized that the depressed patients, particularly ones with suicide attempt history, would differ in sensitivity to loss during decision making, since depressed patients are thought to be susceptible to negative outcomes than positive ones.

We examined the sensitivity to loss in 42 patients with major depressive disorder (patients with suicide attempt history, n=22) and 58 healthy controls using loss aversion and probability discounting task (in gain and loss frame).

Depressed patients, particularly non-medicated patients, exhibited significantly higher loss aversion than healthy controls as shown in Fig. 1 (Mean ± S.D: 3.07±2.46 vs. 2.09±1.18, $p < 0.01$). Antidepressant treatment affected loss aversion in depressed patients marginally ($p = 0.053$), suggesting that neuromodulator system such as 5-HT might be underlying decision making process regarding negative outcomes. In probability discounting, depressed patients showed higher ratio of (discount rate of gain)/(discount rate of loss) than healthy controls, which indicates higher risk aversion (5.48±8.77 vs. 2.23±3.01, $p < 0.01$). Discount rate of loss was significantly differed between patients with and without suicide attempt history (0.90±0.50 vs. 1.68±1.23,$p < 0.05$). In our preliminary fMRI experiment, the insula, the medial prefrontal cortex and the dorsolateral prefrontal cortex were implicated in probability discounting task.

In conclusion, high loss aversion and risk aversion were distinguished as key features of patients with major depression. These loss sensitivity tasks might be useful in quantifying affective/cognitive bias in depressed patients and predicting risk of suicidal attempt.

Title: Changes in perception of risk and valuation of monetary rewards with transition from acute to chronic back pain

Authors: *S. E. BERGER[1], M. N. BALIKI[1], A. T. BARIA[1], E. L. PARKS[1], S. TORBEY[1], K. M. HERRMANN[1], T. J. SCHNIZTER[2], A. V. APKARIAN[3]
[1]Dept. of Physiol., [2]Dept. of Physical Med. and Rehabil., [3]Departments of Physiology, Anesthesia, and Surgery, Northwestern Univ. Feinberg Sch. of Med., Chicago, IL

Abstract: Recent observations show the involvement of nucleus accumbens in chronic pain. This region is part of the mesolimbic neural mechanisms mediating reward valuation, decision-making, and motivation. However, it remains unclear the extent to which the circuitries of pain and reward overlap with and influence one another. Since nociceptive input provides motivational information and value of its own via its function as a primary punisher and as a negative reinforcement, we are interested in exploring the link between reward and pain, specifically for the transition from an acute to a chronic state. Here we assess performance, and compare brain activity, for a monetary gambling task –behavioral loss aversion – and compare the performances of healthy controls (HC, n=21) to those of people with subacute back pain (SBP, n=56) and chronic back pain (CBP, n=14). All SBPs and CBPs were diagnosed by a clinician following IASP criteria; CBPs had back pain >1 year and HCs had no history of back pain. Additionally, SBPs were segregated into two groups: recovering SBP patients (SBPr) were defined as people whose pain was decreased by >20% at the time of the task; all other SBPs were defined as persisting (SBPp).
The task was performed during an fMRI scan. For each trial, subjects were shown a display depicting an amount of potential gain and an amount of potential loss, and after a decision period, had to accept or reject the gamble with a computer mouse. We computed the regression coefficients for each person's loss and gain sensitivity, and their ratio equaled their individual level of loss aversion (lambda). We found no group effect in average lambda, gain, or loss sensitivity values ($p=0.19$); however, there was a significant gender affect, with male participants having higher gain sensitivity than females overall ($p<0.01$). There was also a significant interaction between group and gender, such that males' gain sensitivities increased as they moved farther away from a healthy baseline, with SBP males performing somewhere in between HC and CBP males. Preliminary results of brain activity indicate significant differences in activity within the anterior cingulate during the task. Additional analyses are underway, and more results will be presented at the meeting.
So far, our findings suggest that individuals with back pain exhibit riskier decision-making and may be less loss-averse, implying that the experience of pain changes the experience of monetary reward, although this interaction seems relatively weak and dependent upon gender differences.

Title: Neural correlates of risk during decision-making in older pilots

Authors: *M. M. ADAMSON, D. HERALDEZ, K. MAIN, K. CASTILE, J. TAYLOR, J. YESAVAGE
Psychiatry, Stanford University/VA PALO ALTO, Palo Alto, CA

Abstract: INTRODUCTION: The most lethal accidents in General Aviation are usually caused by improperly executed instrument landing approaches involving descents below the minimum altitude of 200 ft without the use of visual references prescribed by the Federal Aviation Administration (FAA). Older pilots are more likely than younger pilots to take the risk of landing in worse weather conditions than acceptable by FAA rules. Although the individual differences in flight simulator performance have been explained in part by age, expertise and general cognitive ability, the contributions of a specific brain network associated with risky decision making remains unexplored. METHOD: This study evaluates the role of age-related neural changes during a pilot's crucial decision to land or not under difficult weather conditions. Ten young (19-45) and 10 middle-age to old (46-79) instrument certified pilots "fly" a series of short simulated "cockpit view" landing scenarios in the fMRI scanner with conditions in which low visibility (high risk) explicitly favors the no-land choice and high visibility (low risk) favors the land choice. Measures include: landing decision scores (Land(low risk) vs. No Land (high risk)), task-related and resting-state networks (default mode, salience and executive), and structural brain volumes.RESULTS: Initial analyses of age-related differences in task related functional brain activity shows lower activation during the No Land condition in some but not all regions of the default mode network (which consists of posterior cingulate/precuneus, lateral parietal and middle temporal gyrus, and anterior cingulate, superior, and middle frontal gyri) in older pilots compared to younger pilots. CONCLUSION: Decreased activity in default mode network during a risky situation (No Land condition) is modulated by age-related brain changes during real-world everyday task performance.

Title: Dopaminergic contributions to risk taking and temporal discounting: Evidence from Parkinson's disease

Authors: *E. K. BRAUN[1], K. FOERDE[2], B. FIGNER[2,3], E. WEBER[2], D. SHOHAMY[2]
[1]Psychology, [2]Columbia Univ., New York, NY; [3]Univ. of Amsterdam, Amsterdam, Netherlands

Abstract: When making decisions, subjective factors -- such as one's willingness to take risks or wait for better outcomes -- often influence choices. Previous research has shown that both risk taking and temporal discounting are modulated by striatal dopamine, but questions remain about the causal role of dopamine in these behaviors. Parkinson's disease is characterized by a loss of dopaminergic inputs to the striatum, providing a model for better understanding the role of striatal dopamine in specific aspects of decision making. Here, we tested patients in the mild to moderate stage of Parkinson's disease and healthy controls on two decision making tasks: one that assesses risk taking (the Columbia Card task) and one that assesses temporal discounting (Intertemporal Choice task). Additionally, to characterize how modulating dopamine levels in patients alters risk taking and temporal discounting behavior, we tested Parkinson's patients both on and off dopaminergic medication. We found that Parkinson's patients made riskier choices than matched controls. Specifically, Parkinson's patients were less sensitive to an increased probability of loss, and this effect was enhanced when patients were tested on dopaminergic medication. On the Intertemporal Choice task, we found that Parkinson's patients were more patient than controls, that is they discounted less for time than controls. Preliminary results suggest that this effect was especially strong among Parkinson's patients tested while on medication. Together, these results support the idea that striatal dopamine modulates risk-taking and temporal discounting. These results also raise important questions regarding the mechanisms by which dopamine modulates different aspects of decision making in both health and disease.

Title: Neurobiological determinants of risk-taking: The influence of recent experience, frontolimbic activation, and dopamine D2/D3 receptors

Authors: *M. KOHNO[1], D. G. GHAHREMANI[2], A. M. MORALES[1], C. L. ROBERTSON[3], K. ISHIBASHI[2], A. T. MORGAN[2], R. A. POLDRACK[6], M. A. MANDELKERN[4], E. D. LONDON[3,5]
[1]Neurosci. Interdepartmental Program, [2]Dept. of Psychiatry and Biobehavioral Sci., [3]Dept. of Mol. and Med. Pharmacol., Univ. of California, Los Angeles, CA; [4]Dept. of Physics, Univ. of California, Irvine, CA; [5]Brain Res. Inst., Univ. of California, Los Angeles, CA; [6]Departments of Psychology and Neurobio., Univ. of Texas, Austin, TX

Abstract: Despite progress in our understanding of risky decision-making, the factors that influence decisions involving risk are not well understood. Neuroimaging studies have provided evidence of a distributed neural network involved in decision-making; however, decision-making has often been evaluated independent of recent experience. The experience of losses and rewards has been shown to affect fronto-limbic and dopaminergic-brain regions respectively, but their affects on the circuitry underlying risky decision-making are poorly understood. In addition, animal studies have shown a reduction in the number of risky choices with administration of D2-receptor agonists suggesting a major role for dopamine in risky decision-making. The links between dopamine and the effects of choice-outcome on the circuitry underlying risky decision-making, however, are unknown. Using the Balloon Analog Risk Task (BART), a computerized task used to evaluate the propensity for risk-taking, we sought to evaluate the role of striatal D2-like dopamine receptors in the circuitry underlying risky decision-making and the effects of recent outcomes on risk-taking behavior and associated neural activity. In the BART, participants are presented with a series of choices in which they risk losing accumulated earnings for greater potential gains by pumping a virtual balloon. The alternate choice is to cash out and retain accrued earnings. Neural activation was assessed using fMRI paired with the BART in

healthy participants (n=60,18-51yrs.; 27 F/33 M), and striatal-dopamine D2-like-receptor availability was measured by [18F]fallypride positron emission tomography in a subset of the sample (n=13).
After explosion but not after cashing out, participants made fewer pumps, and activation in amygdala and hippocampus showed greater sensitivity to risk ($p<0.05$, whole-brain corrected). Ventral striatal D2-like receptor availability and sensitivity of activation to level of risk and reward while cashing out was negatively related to (i.e., predicted reduction in) risk-taking on the next trial ($r= -0.798$, $p= 0.002$; $r= -0.778$, $p= 0.002$). D2-like receptor availability was also negatively correlated with sensitivity of activation to level of risk in the DLPFC while pumping ($r= -0.751$, $p= 0.004$). Both measures were related to total earnings (BP(ND): $r= -0.596$, $p= 0.027$, BOLD: $r= 0.740$, $p= 0.005$), suggesting a mechanism by which an interactive system of frontal and striatal regions supports adaptive risk-taking. These findings are the first direct evidence for a potential mechanism by which dopaminergic pathways within frontostriatal networks determine risk-taking behavior.

Title: Gambling for the big win: Enhanced memory for extreme outcomes drives risky decisions

Authors: C. R. MADAN[1], E. A. LUDVIG[2], *M. SPETCH[1]
[1]Psychology, Univ. of Alberta, Edmonton, AB, Canada; [2]Princeton Neurosci. Inst., Princeton Univ., Princeton, NJ

Abstract: Would you rather a guaranteed $20 win or a 50/50 chance at winning $40? What about sustaining a guaranteed $40 loss vs. a 50/50 chance of losing $40 dollars? A classic result

from behavioral economics is that people usually choose the guaranteed win (i.e., are risk averse) in the gain context, but choose the gamble (i.e., are risk seeking) in the loss context.
This change in risk sensitivity for gains and losses, known as the reflection effect, holds for a broad range of experiments when people are explicitly told the outcomes and probabilities. Recent results, however, have shown that when people learn about the outcomes from their own experience, this reflection effect can reverse with people becoming risk seeking for gains and risk averse for losses.
In a series of experiments, we show that this reversal in risk preference is driven by an overweighting of the extreme or peak outcomes in decisions made from experience. That is, the biggest win and the biggest loss in a given context are overweighted when evaluating risky options that can lead to these outcomes. This overweighting creates a bias toward risk seeking for gains and risk aversion for losses.
We hypothesize that extreme outcomes are overweighted in decision processes due to memory biases. In the example above, this hypothesis supposes that a win of $40 is more memorable than an outcome of $0. As a result, the risky option has a subjectively higher value than the guaranteed win, leading to risk seeking. In contrast, when an extreme loss of $40 is similarly overweighted, the risky option has subjectively more negative value than the guaranteed loss, leading to risk aversion.
In the experimental task, participants were presented with pairs of doors, with each door leading to a fixed or risky gain or loss. Experiment 1 confirmed that participants showed a reversed reflection effect with experience in our procedure. Experiment 2 manipulated reward magnitude and showed that the reversed reflection effect occurred only for doors leading to the relatively most extreme outcomes. Experiment 3 split gains and losses between subjects and found risk seeking for the highest value outcome in both cases.
These results suggest that memory biases for extreme outcomes may drive behavior for experience-based risky decisions. More broadly, gambling behavior may also be driven by this memory bias, where people continue to gamble for the memorable big win despite sustaining multiple smaller, and thus forgettable, losses.

Title: An MEG study of risk and overconfidence in pathological gamblers

Authors: *M. E. HUDGENS-HANEY[1], J. P. HAMM[1], A. S. GOODIE[1], E. A. KRUSEMARK[2], J. E. MCDOWELL[1], B. A. CLEMENTZ[1]

Abstract: Studying the neural correlates of confidence and risky decision making may be useful for understanding mechanisms associated with pathological gambling. The present study compared MEG responses of 34 pathological (PG) and 34 non-pathological (NPG) gamblers during the Georgia Gambling Task (Goodie, 2003). Participants completed the Diagnostic Interview for Gambling Severity and South Oaks Gambling Screen, measures of gambling pathology, and a standard confidence assessment task using 180 pairwise comparisons of populations of states. In a subsequent MEG task, participants viewed the same comparisons (Judgment; 2000 ms), or a probability-matched random event, followed by the number of points that could be lost during that trial (Decision; 1500 ms), and indicated with a button press whether they chose to bet on their decision. After bet acceptance or rejection, participants received feedback on whether they won or lost.
Recordings were obtained using a 143 channel whole head MEG system. Using spherical head models and L2 minimum norm, we localized ERFs. Baseline differences and task related changes during the initial 750ms of the Judgment task phase were computed as a function of group and confidence level (2-way ANOVA).
There were a number of interactions between gambling pathology and high (HC) versus low confidence (LC). NPLC (Non-pathological gambler, low confidence) initially show decreased activation in right occipital temporal cortex. During later processing, however, NPLC show increased activity in this region, while NPHC show greater activity than NPLC in left occipital temporal cortex. As these regions support identification of behaviorally relevant stimuli, it is interesting that occipital temporal cortex in PG did not distinguish between confidence levels at any time. This complements other insensitivities in this region in PG (Camchong et al, 2007) and suggests that manifestations of top-down bias signals in early sensory processing are disregulated in PG. During early and late processing, NPLC show decreased activity in parietal cortex, consistent with electrophysiological studies in rats (Kiani et al, 2009). PGLC show early increased activation throughout dorsal and ventral visual processing streams, which persists in the left lateral prefrontal cortex. While right anterior PFC is associated with higher levels of confidence (Camchong et al, 2007) and metacognitive awareness (Flemming et al, 2012)., NPHC show decreased activity in right posterior PFC. These findings suggest that regions of right PFC differentially code confidence information, and suggest a deficit in PGs' higher cognitive processing related to decision making.

Title: Are Ambiguity aversion and ambiguity intolerance identical? : A neuroeconomics investigation.

Authors: Y. TANAKA[1], T. IDENO[3], S. OKUBO[3], K. TAKEMURA[3], J. MIYATA[1], R. KAWADA[1], S. FUJIMOTO[1], *M. KUBOTA[1], A. SASAMOTO[1], N. SAWAMOTO[2], H. FUKUYAMA[2], T. MURAI[1], H. TAKAHASHI[1]

Abstract: 1. Background:
In the field of decision making research, ambiguity aversion describes an attitude of preference for a gamble in which the probability of an outcome is known over a gamble in which the probability of an outcome is unknown. On the other hand, ambiguity intolerance has been defined as the tendency to resort to black-white solutions to arrive at premature closure. It is not clear whether these two notions derived from different disciplines are identical or not. To clarify this issue, we first compared the degree of ambiguity aversion with the degree of ambiguity intolerance in behavior level. Then, we investigated neural correlates of these two measures using voxel-based morphometry (VBM).
2. Methods:
Twenty-four healthy volunteers participated in this study. We investigated the relationship between individual ambiguity aversion tendency and individual ambiguity intolerance tendency by behavioral experiments (Choice under risk and ambiguity Task) and questionnaire (The Need for Closure Scale (NFCS)). We also administered the self-report version of the Revised NEO Personality Inventory (NEO-PI-R). Furthermore, the neuroanatomical correlates of ambiguity aversion tendency and ambiguity intolerance tendency were investigated by measuring the gray matter (GM) concentration using VBM.
3. Results:
Most subjects exhibited ambiguity aversion. The ambiguity aversion parameter measured by a

decision-making task was not correlated with the score of ambiguity intolerance, subscale of NFCS. However, ambiguity aversion parameter was correlated with agreeableness score of NEO-PI-R. While ambiguity aversion parameter were correlated with GM density in right inferior parietal lobule and left inferior frontal gyrus, score of ambiguity intolerance was not correlated with GM density in any region.

4. Conclusions:

Ambiguity aversion described in decision theory may not necessarily identical to ambiguity intolerance referred in clinical psychology. Cautious applications of decision theory to clinical neuropsychiatry are recommended.

Title: Dissociative relationships between impulsivity and dopamine D2/D3 receptor availability in the striatal subregions

Authors: H. PARK, B. MOON, B. LEE, *S. KIM
Nuclear Med., Seoul Natl. Univ. Coll Med., Seongnam, Korea, Republic of

Abstract: Impulsivity is significantly associated with the risk-taking behaviors including addiction and is linked to the dopamine D2/D3 receptor availability in the striatum which is separable into functional subregions (limbic, associative and sensorimotor). We investigated the relationships between the impulsiveness and dopamine D2/D3 receptor availability in the striatal subregions using [18F]fallypride and positron emission tomography (PET).
Six healthy men underwent dynamic [18F]fallypride PET studies to measure striatal dopamine D2/D3 receptor availability in terms of binding potential (BPND). Non-planning (NPimp), motor (Mimp) and attentional (Aimp) impulsiveness of subjects were assessed using the Barratt Impulsiveness Scale version 11 (BIS-11), which is consisted of total 23 likert items of 4-point scale. Striatal subregions were delineated on the individual magnetic resonance images and five subregions were defined as the precommissural dorsal caudate (preDCA), -putamen (preDPU), postcommissural-caudate (postCA), -putamen (postPU), and the ventral striatum (VST). BPND

and BIS-11 score were incorporated into the linear and non-linear regression analysis. Subjects showed varied levels of impulsiveness in BIS-11 score; NPimp (ranged 8-23 points), Mimp (ranged 4-20 points) and Aimp (ranged 7-18 points). In the preDCA, a part of the associative striatum implicated in the cognitive function, significant linear correlation was found between BPND and NPimp, Pearson R = .87, P = .026. The relationship between BPND and the sum of NPimp, Mimp and Aimp was better described by non-linear regression analysis, Pearson R = .98, P = .008, in the preDCA. BPND of the postCA, a part of the associative striatum, was linearly correlated with NPimp, Pearson R = .79, P = .062, Mimp, Pearson R = .79, P = .059, and Aimp, Pearson R = .81, P = .049. In the VST, a part of limbic striatum, the inverted-U-shaped relationships were shown between BPND and NPimp, Mimp and Aimp scores.
These data demonstrates that striatal dopamine D2/D3 receptor availability is associated with impulsivity. They also suggest that striatal subregions may play differential roles in the modulation of impulsivity.

Title: Differences in dopaminergic response to unpredictable rewards in the right ventral Striatum in Fibromyalgia patients: A 11C-raclopride bolus plus constant infusion PET-study

Authors: K. LEDERMANN[1], J. JENEWEIN[1], H. SPROTT[4], G. HASLER[5], U. SCHNYDER[1], C. BURGER[2], A. JOHAYEM[2], T. CSERVENYAK[2], S. KOLLIAS[3], A. BUCK[2], *C. MARTIN-SOELCH[6]

Hosp. of Adult Psychiatry Bern, Bern, Switzerland; [6]Unversity Fribourg, Dept. of Clin. Psychology, Fribourg, Switzerland

Abstract: Emerging evidence demonstrates the important role of the mesolimbic dopamine system (DA) in the processing of pain and reward. A DA hypofunction has been reported in chronic neuropathic pain. Fibromyalgia syndrome (FMS) is a non-neuropathic chronic pain disease, in which first indication of DA dysfunction was also evidenced. FMS is frequently

associated with depression: Reduced DA function and reduced responses to reward were also evidenced in depression.
Therefore reduced DA reactions to rewarding stimuli could be involved in the depressive or pain symptoms observed in FMS. Here, we tested differences between FMS patients and healthy subjects in striatal DA release in response to unpredictable monetary rewards using the bolus plus infusion (B/I) PET-method. We expected FMS patients to show a reduced endogenous DA release, expressed by increased [11C] raclopride binding and expected these changes to correlate with depression and pain scores. Eighteen female FMS patients and sixteen healthy subjects were measured at rest and while performing a slot machine task consisting of a sensorimotor control condition and a monetary reward condition where subjects randomly received monetary rewards in an unpredictable fashion. Regional PET measures were acquired in MRI-based striatal regions of interest. Percent of change in [11C] raclopride binding was computed as the difference in ratio region/cerebellum. We found significant higher [11C] raclopride binding ratios in FMS patients than in healthy subjects across the different measurement conditions in the right ventral striatum ($p=0.04$). The percent of change between sensorimotor and reward condition was significantly larger in FMS than in healthy participants. No significant correlations with pain and depression scores emerged. These results point to an involvement of the DA function in the pathophysiology of FMS consisting in a reduced DA function at rest and unexpectedly in a hypersensitive reaction to rewards.

Title: Neural activation during risk-taking relates to risky sexual behavior in adolescents

Authors: *D. GOLDENBERG[1], E. H. TELZER[1], A. FULIGNI[2], A. GALVAN[1,3]
[1]Psychology, [2]Psychiatry and Biobehavioral Sci., [3]Brain Res. Inst., UCLA, Los Angeles, CA

Abstract: Relative to children and adults, adolescents engage in increased sexual risk-taking behaviors. Although young people represent only one-quarter of the sexually active population, they account for a disproportionate amount of sexually transmitted infections (STIs) and unintended pregnancies each year. In this study, our goal was to examine the relationship between risky sexual behavior and neural correlates of risk-taking.
Twenty-one sexually active adolescents (ages 14 -16 years) were recruited from local schools; 13 adolescents reported engaging in risky sexual behavior (e.g. lack of condom use). Risk-taking was assessed during functional magnetic resonance imaging (fMRI) using the Balloon Analogue Risk Task (BART). On each trial of the BART, participants
choose whether to inflate a balloon, which increases earnings, or to cash-out before the balloon explodes. Here, inflations and cash-outs are indices of risky and cautious decisions, respectively. fMRI analyses contrasted
the blood oxygen level dependent (BOLD) response during risky and cautious choices. Behaviorally, there was a significant negative correlation between frequency of risky sexual behavior and mean reaction time for inflations ($r=-.30$, $p<.05$); subjects reporting greater risky sexual activity were significantly faster at inflating the balloons, suggesting a greater orientation toward impulsivity. The fMRI results revealed that risky sexual behavior was negatively associated with activation during cautious decisions
(i.e., cash-out trials) in the parietal cortex, a region implicated in decision-making and risk processing, and insular cortex, a region implicated in emotion regulation and risk prediction. These results suggest that risky sexual behavior in adolescents is associated with neural activation during risky decision making. To our knowledge, no research has yet examined the link between risky sexual behavior in adolescents and the brain. The implications of this study may help elucidate neurocognitive indicators for the development of risky
sexual behaviors. More knowledge of these factors could have high utility in informing interventions aimed at preventing and reducing teenage pregnancy and sexually transmitted diseases.

Title: Investigating a resting baseline for functional near infrared (fNIR) imaging

Authors: M.-J. CARDIN[1], A. RODRIGUEZ MERZAGORA[2], K. IZZETOGLU[2], *P. A. SHEWOKIS[3], B. ONARAL[2]
[1]Psychology, Wesleyan Univ., Middletown, CT; [2]Sch. of Biomed. Engin. Sci. and Hlth. Systems, [3]Col. of Nursing and Hlth. Professions, Drexel Univ., PHILADELPHIA, PA

Abstract: Neuroimaging studies often rely on a 'resting baseline condition'. However the definition of such a condition and its interpretation are still elusive. In this preliminary study, we utilize functional near infrared (fNIR) spectroscopy for the investigation of resting conditions. fNIR is a field deployable neuroimaging modality that enables the monitoring of changes in oxyhemoglobin and deoxyhemoglobin concentration in the prefrontal cortex. We investigated these biomarkers during resting baseline in fNIR spectroscopy measures.
While changes in oxyhemoglobin are affected by local blood flow, changes in deoxyhemoglobin levels mostly reflect local oxygen consumption, which should be minimal in absence of meaningful cognitive activation. Hence, we hypothesize that deoxyhemoglobin would overall provide a more stable resting state index than oxyhemoglobin. To test this hypothesis, fNIR signals were collected from three healthy subjects across 11 sessions each. Participants were asked to sit quietly with their eyes closed for 1 minute and with their eyes open for 1 additional minute, while staring at a computer screen. fNIR signals were collected from the subjects prefrontal area at two different wavelengths from 16 channels. Changes in oxy- and deoxyhemoglobin concentrations were computed using the modified Beer-Lambert law. Statistical analyses of the collected fNIR measures indicated that deoxyhemoglobin levels were more stable across the 11 sessions as compared to oxyhemoglobin levels, in agreement with our hypothesis.
Stability of deoxyhemoglobin values can be used as a parameter to validate resting baseline conditions in neuroimaging studies. Furthermore, future studies will be undertaken to investigate if a low cognitive load task, such as the Psychomotor Vigilance Task, could be used as a 'cognitive baseline condition' yielding stable readings not only in terms of deoxyhemoglobin, but also in oxyhemoglobin measures.

Title: Laser surgical preparation of awake fruit flies for fluorescence imaging of neural activity.

Authors: *S. SINHA[1], L. LIANG[2], L. LUO[3,4], T. M. BAER[2], M. J. SCHNITZER[1,4]
[1]Applied Physics/Biology, [2]Applied Physics, [3]Biol., Stanford Univ., Stanford, CA; [4]Howard Hughes Med. Inst., Chevy Chase, MD

Abstract: The fruit fly, Drosophila melanogaster, is a model organism that is used across multiple areas of neuroscience. Recent improvements in genetically encoded calcium indicators (GECIs) and fluorescence microscopy have facilitated in vivo imaging of neural dynamics in fruit flies and are well poised to help address how neural circuit dynamics underlie fly behavior. However, a main experimental limitation in the study of neural circuits is the low rate at which brain-imaging data is acquired, typically limited to a few animals per day. For fruit flies, manual dissection of the cuticle to create an optical window for brain imaging is a time-consuming process that requires considerable surgical skill and practice and introduces undesired variability between experiments. Further, removal of the cuticle with sharp forceps or scissors can cause physical trauma to the brain that compromises the fly's behavior.

To remove the fly cuticle in an automated fashion we developed a microsurgery system based on a nanosecond-pulsed 193-nm laser. We chose the wavelength and pulse duration to enable tissue removal with minimal heating of the fly or bleaching of the fluorescent GECI. Our computer-controlled system can cut optical windows in the cuticle 10-500 μm in width using ~1 s of laser illumination. Following microsurgery, we imaged various brain regions in the fly's olfactory and visual systems. We assessed the effects of the laser surgery on fly behavior by measuring post-surgical phototactic responses. Using a T-maze, we found that phototaxis was not significantly degraded for laser dosages of less than 90 pulses. We thus conducted all imaging experiments below this threshold.

The laser microsurgery protocol we developed provides more precise control of the size and depth of the surgical cut as compared to manual dissection methods. This enables us to minimize the surface area of the brain that is exposed to the environment without compromising the quality

of the measured neuronal calcium transients. To illustrate, we opened a 120 µm x 90 µm hole in the fly cuticle to image the Kenyon cells in the mushroom bodies. Using isoamyl acetate and geranyl acetate as stimulating odors, we recorded odor-evoked neuronal calcium transients. We observed such calcium transients with ΔF/F values exceeding 40% even 18 hours after surgery. This 18-hour imaging duration is apparently at least a two-fold increase over the longest duration for in vivo optical imaging previously reported for live flies. This extension of the experimental duration should help facilitate time-lapse imaging studies of individual flies, such as those intended to examine experience-dependent changes in neural dynamics.

Title: Superior response kinetics of circularly permuted fluorescent proteins as reporters in CiVSP-based voltage sensors

Authors: J. PLATISA[1], L. BARNETT[2], M. POPOVIC[3], T. HUGHES[2], *V. A. PIERIBONE[4]
[1]The John B. Pierce Laboratory, Inc., New Haven, CT; [2]Montana State Univ., Bozeman, MT; [3]Cell. and Mol. Physiol., Yale Univ. Sch. of Med., New Haven, CT; [4]John B Pierce Laboratory/Yale Univ., NEW HAVEN, CT

Abstract: Currently the most successful fluorescent protein-based voltage probes use the voltage sensing domain of the *Ciona intestinalis* voltage sensitive phosphatase (CiVSP). Recent advances in the calcium sensor field have shown that circularly permuted green fluorescent proteins (cpGFP) can produce robust signals. To determine whether such an approach could improve the CiVSP-based voltage sensors, we produced a matrix of different CiVSP/cpGFP fusion constructs (90) and tested these for cellular distribution and/or voltage sensitivity in HEK

cells and cultured hippocampal neurons. We found a direct relationship between a probe's responsiveness to voltage changes and the fluorescent protein's "hole" size and insertion site within the CiVSP. Our best probe found to date, ElectricPk exhibits a modest fluorescence signal change (~-1.2% ΔF/F for +100mV depolarization) but has remarkably fast on and off kinetics (~2ms). The probe exhibits very little of the slow response component which plagues other CiVSP-based probes. This rapid response speed facilitated action potential detection in cultured hippocampal neurons. The optical signal had a shape that was nearly identical to that of the voltage recording of the action potential. In addition, the probe exhibited an unusually linear ΔF/ΔV response profile to both depolarizing and hyperpolarizing voltage changes. These probes are the first CiVSP-based probes capable of accurately capturing the rapid movements of the voltage sensor and as such support the use of circularly permuted versions of fluorescent proteins in the design of voltage sensitive probes.

Title: ScanImage, software for *in vivo* laser scanning microscopy

Authors: *V. IYER[1], S. PERON[1], G. M. G. SHEPHERD[2,1], K. SVOBODA[1]
[1]HHMI/Janelia Farm, Ashburn, VA; [2]Dept of Physiology, Feinberg Sch. of Med., Northwestern Univ., Chicago, IL

Abstract: *ScanImage* is freely available software (scanimage.org) for laser scanning microscopy, in particular two-photon laser scanning microscopy (TPLSM). Adoption of *ScanImage* is growing rapidly; it is now used by over 150 laboratories. Two versions of *ScanImage* are currently supported: *ScanImage* 3.8 allows galvanometer based scanning and *ScanImage* 4.1 is for resonant scanning hardware (Thorlabs). Galvanometer scanning is widely used and offers flexible scan modes, such as line and point scanning. Resonant scanning supports scan rates up to 16kHz – an order-of-magnitude speed-up compared to galvanometer scanning. *ScanImage* 3.8 and 4.1 have similar user interfaces and capabilities, but distinct codebases. *ScanImage* 3.8 replaces previous 3.x versions, adding 'cycle' mode capability for automation of

imaging sequences, new region-of-interest (ROI) scanning capabilities, and compatibility with a 64-bit operating system. *ScanImage* 4.1 improves several performance characteristics compared to its predecessor (version 4.0). Multiple samples are now averaged for each pixel, optimizing signal-to-noise throughout the field-of-view and for all pixel rates. Data buffering is improved, reducing the probability of losing image frames during continuous acquisition. *ScanImage* 4.1 supports higher frame rates (fewer lines-per-frame) and faster stack acquisitions, and adds frame-count tagging for each individual frame of acquired data logged to a TIF image file. *ScanImage* 4.1 has been optimized for volume imaging, using fast axial scanning based on piezoelectric actuators synchronized to resonant scanning. Both *ScanImage* 3.8 and 4.1 facilitate the binding of customized *user functions* to one or more *ScanImage*-defined events. This approach can be used for a wide range of user requirements, ranging from simple customization to creation of elaborate and powerful 'plugins'. Future development will be aimed at unifying versions 3.x and 4.x into a consolidated release capable of supporting multiple scanheads, e.g. both galvanometer and resonant scanning, either in parallel or in series.

Title: Simultaneous optical and electrical measurement of neurovascular coupling in awake rats

Authors: J. SUTIN[1,2], W. WU[1], L. RUVINSKAYA[1], *M. A. FRANCESCHINI[1]
[1]Radiology, Massachusetts Gen. Hosp., CHARLESTOWN, MA; [2]Pathology, Boston Univ., Boston, MA

Abstract: Neurovascular coupling, the coordination of changes in metabolic demand from neuronal tissue with vascular regulation of localized blood perfusion, has previously been investigated by diffuse optical imaging and trans-cranial EEG in anesthetized rats. To overcome the profound impact of anesthetics on brain hemodyamics and electrical activity, we have developed an implantable electro-optical probe for longitudinal measurements in fully awake rats.

Our probe allows, in a minimally invasive format, simultaneous electrical measurement of neuronal activity by EEG and optical measurement of the hemodynamic response by diffuse optical spectroscopy. A survival surgery is performed to remove the superficial tissue above the rat skull, install EEG screw electrodes and anchor the implant to the bone. In this manner, cerebral hemodynamic measurements are made without interference from blood flow in the scalp. Furthermore, the skull is kept fully intact, minimizing perturbation to the brain and its vascular networks.
During measurement, a custom designed connector is attached to the implant, making electrical connections to the EEG electrodes and holding optical fibers in rigid contact with the skull. On each side of the skull, a single source fiber illuminates the brain with two wavelengths of near-infrared light. Four detector fibers per side allow for regional measurement of evoked changes of cortical oxy and de-oxy hemoglobin concentrations from changes in light transmission between source and detector. The optical fibers and EEG electrode are positioned for maximum sensitivity over SI. Whisker stimulation is performed electrically via chronic electrodes implanted subcutaneously in the whisker pad.
Rats are conditioned to remain restrained during measurements. Awake subjects enter a tubular body restraint and their heads are immobilized via the skull implant. Animals can be maintained in either fully awake state or various levels of anesthesia can be applied.
We have measured response to different frequency and intensity whisker stimulation on both awake and anesthetized rats. Preliminary results find a larger hemodynamic response in fully awake rats. In addition, higher intensity stimulation results in greater regional activation associated clear changes in the EEG signal. Experiments to systematically measure these effects in awake and anesthetized animals are currently underway.

Abstract: We have previously shown that pulsed infrared light can be used to excite neurons with high spatial resolution and low invasiveness in the somatosensory cortex of rodents. However, whether this method can be used effectively in the cortex of non-human primates is unknown. In this study, we evaluated pulsed infrared optical stimulation of cortex in squirrel monkeys and its potential for functional tract tracing. Stimulation of the visual cortex generated excitatory neuronal electrical responses as assessed with single unit recordings. Moreover, optical imaging of the cortical region during pulsed infrared stimulation revealed activation of nearby functionally related sites, indicating a novel way to study local intra-areal connectivity. We also investigated the use of optical stimulation in a functional magnetic resonance (fMRI) environment. In a high field (9.4T) scanner we recorded images of primary somatosensory cortex (S1) of squirrel monkeys during optical stimulation of a single digit location in Area 1. Optical stimulation was introduced via a fiberoptic and a newly developed long-term MR-compatible, optically transparent window. We found that optical stimulation evokes significant changes in cerebral blood volume (CBV) weighted MR signals. Such signals are known to correlate with neural activity. We found that the magnitude of the CBV changes and the activated region of cortex increased with radiant exposures. Furthermore, we observed that the light stimulation can not only directly drive the stimulated site, but also peripheral cortical activity. Stimulation of a single digit location in Area 1 resulted in focal, digit-specific activation in Areas 3b, 2, and possibly 3a. Such activations were confined primarily to the middle layers in these nearby areas. These data demonstrate that pulsed infrared laser excitation, used in conjunction with optical imaging or with fMRI, is a useful technique for functional tract tracing technique in vivo, which can reveal both local and global connectivity patterns.

Title: Live imaging and motor unit function during progressive neuromuscular synaptic degeneration

Authors: *R. BROWN, R. R. RIBCHESTER
Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: Diagnosis of Amyotrophic Lateral Sclerosis (ALS) is currently informed by a combination of symptomatic presentation and interpretation of functional deficits, supported by electromyography (EMG). Recent development of new criteria for EMG analysis allows earlier diagnosis, and shows abnormalities in non-symptomatic areas. However, variation in onset times and detection of objective disease signs, for instance in animal models such as the SOD1 mouse model of ALS, still hinders accurate diagnosis and the monitoring of disease progression, or the efficacy of treatment. Therefore it is desirable to develop more direct ways of monitoring disease progression in vivo. EMG recording is also “blind” to the direct and progressive effects of disease on the morphology of motor units and their constituent neuromuscular junctions (NMJ). Direct imaging of motor units should therefore address some of these concerns. Using mice expressing fluorescent protein in their axons we have combined EMG recording via fine monopolar needles with fibre-optic confocal microendoscopy (CME), a method of live imaging of nerves and neuromuscular junctions. We use a Mauna Kea Technologies CellVizio system to image NMJ and an ADI Powerlab system to monitor the EMG. We have successfully monitored slow, progressive degeneration of motor nerve terminals and axons in transgenic thy1.2 YFP16 Wld^{s} mice, in which Wallerian degeneration is about ten times slower than in wild-type mice. We imaged the degeneration of axons and nerve terminals following unilateral sciatic nerve section up to two weeks in vivo, and recorded the EMG from the same vicinity as the motor endplates we imaged. This technique of visualising both structural and functional deficits will not only facilitate the study of animal models but conceivably allow earlier, reliable diagnosis

and monitoring of disease progression in ALS and other neuromuscular diseases, which would allow more rapid entry to and measurement of efficacy in clinical trials. Safe, high-contrast fluorochromes that selectively stain different components of NMJ will be required for full translation of this possibility to human subjects, however.

Title: Reliable detection of single action potentials and synaptic calcium signals using improved genetically-encoded calcium indicators

Authors: *T.-W. CHEN, J. YU, R. A. KERR, V. JAYARAMAN, L. L. LOOGER, K. SVOBODA, D. S. KIM
HHMI Janelia Farm Res. Campus, Ashburn, VA

Abstract: Genetically-encoded calcium indicators (GECIs) allow non-invasive measurement of neuronal activity in vivo. Currently available GECIs, such as the widely used GCaMP3, still suffer from limited sensitivity. Using structure-guided mutagenesis and high-throughput screening, we increased the fluorescence change in response to single action potentials (APs) by >10-fold compared to GCaMP3. We also accelerated the kinetics by ~2-fold. These new GECIs reliably report single APs in single trials in vivo with near 100% accuracy. In the mouse visual cortex, we detected ~5-fold more visually responsive neurons. The sensitivity, dynamic range and speed of the new GECIs exceed those of the synthetic indicator OGB-1. The improved sensitivity further facilitated reliable measurement of synaptic calcium signals in the dendrites of pyramidal cells and parvabumin (PV)-positive interneurons in vivo. Hot spots of orientation-selective domains can be resolved both in single pyramidal cell spines and small segments of PV cell dendrites. These improved GECIs will permit a more complete description of neuronal circuit function and enable long-term functional imaging of single synapses.

Title: An implantable CMOS-based device with hexagonal shape for wide-area brain functional imaging

Authors: *M. HARUTA, T. KOBAYASHI, C. KITSUMOTO, T. NODA, K. SASAGAWA, T. TOKUDA, J. OHTA

Abstract: To explore brain functions based on coordinative neural activities in different domains in a brain, there is a large demand for simultaneous multi-domain observation technique. Multi-domain fluorescence imaging will be a very powerful solution to understand inter-region coordinative activities. The authors have been developing techniques to observe neural activity using CMOS-based implantable imaging devices. These devices are advantageous in in vivo fluorescence imaging, especially under freely-moving situations. We implanted the imaging device in the mouse brain and demonstrated continuous imaging of neural activities. It means that our CMOS-based imaging system can be applied to behavior experiments. However, our previous sensors had small imaging area as 1-3 mm2, and thus not suitable to observing multiple domains in a brain in detail. In this study, we have developed a CMOS-based imaging system for a wider-area brain imaging that includes multiple brain functional imaging. We propose a new sensor design with multiple hexagonal CMOS-based imaging devices. The hexagonal shape is advantageous to configure a wider and multi-domain spherical imaging area on the brain. We integrated LEDs for illumination / excitation, and absorptive light filter for fluorescence imaging. We demonstrated fluorescence imaging using the multiple hexagonal CMOS-based imaging devices on the brain of the mouse. In the experiment, we injected fluorescence beads into the brain surface to prove the function of the device, and successfully observed the injected beads that were excited by LEDs mounted on the imaging devices. New imaging system is expected to be a powerful solution for wide-area, multi-domain brain imaging.

Title: Improved blood velocity measurements with a hybrid image filtering and iterative radon transform algorithm

Authors: *P. Y. CHHATBAR, P. O'HERRON, P. KARA
Neurosciences, Med. Univ. of South Carolina, Charleston, SC

Abstract: The determination of blood velocity changes in individual vessels is an important aspect of understanding neurovascular coupling. A variety of methods have been proposed to determine blood velocity in space-time image sequences, such as singular value decomposition (Kleinfeld *et al*, 1998, PNAS), radon transform (Drew *et al*, 2009, J Comput Neurosci), signal deconvolution (Kamoun *et al*, 2010, Nat Methods) and global energy minimization (Deneux *et al*, 2011, IEEE Trans Med Imaging). Of these, the radon transform has relatively easy implementation and fast data processing. However, the accuracy of the velocity measurements is dependent on the angle step-size used for the radon transform. This creates a trade-off between the speed and accuracy of velocity measurements at a particular image resolution. Moreover, factors like image contrast, imaging depth, movement artifacts and image acquisition speed can potentially lead to erroneous velocity measurements. Here we develop a robust algorithm with high accuracy and fast implementation that can address these hurdles towards accurate blood velocity measurements.
Two-photon imaging experiments were performed in anesthetized cats and rodents. The vasculature was visualized with circulating fluorescein dextran and arterial walls were selectively labeled with Alexa Fluor 633 Hydrazide (Shen *et al*, 2012, Nat Methods). Sensory-evoked changes in blood velocity were recorded using linescan acquisition routines, where moving red blood cells (RBCs) produced streaks in the recorded space-time images with angles proportional to the their velocity. These space-time images were processed with the hybrid algorithm as follows. An average smoothing filter was applied to suppress noise. Then, RBC streak margins were enhanced using a Sobel filter. Next, a series of iterative radon transforms was performed to find the angle value with maximum variance in the radon transform space. The first iteration used a large angle step-size spanning a full range of angle values. The reliability of the measured angle for the first iteration was assessed using the maximum-to-mean variance

ratio. Subsequent iterations used progressively smaller angle step-sizes with the range of angles centered on the angle that had the maximum variance in the previous iteration. The smallest angle step-size was determined by the image segment resolution and once this angle step-size was achieved, the iterative radon transform was terminated. Compared with previous methods, our hybrid algorithm is more sensitive to detecting changes at high blood velocities, provides superior angle precision and requires fewer radon transform cycles.

Abstract: Methods for monitoring neural activity from freely moving animals are vital for understanding a neural basis underlying animal behavior. For truely free behavior the recording system should not constrain the animal which is best achieved with wireless systems. While relatively common with electrical recordings, a wireless approach to optical recordings has become a priority, particularly given the recent explosion in optical methods. Here we describe a wireless system for recording fluorescence signals revealing intracellular calcium activity in freely moving mice. The system consists of two main devices: 1) an epifluorescence microscope with an LED, photo diode, excitation filter, dichroic mirror, emission filter and a gradient index (GRIN) lens (miniaturized with dimensions 10 x 10 x 7.75 mm and 2.0 gram). 2) A circuit board that divided into two parts because of stabilizing the center of balance: one with batteries, an amplifier, power supply circuitry and a light control IC with dimensions 20 x 22 mm. The other consists of a transmitter and a microcomputer with dimensions 20 x 20 mm. The total weight mounted on the back of the mouse is 7.7 g. For calcium recordings, the calcium-sensitive indicator (Oregon green 488 BAPTA-1 AM) was loaded into a glass pipette and pressure-injected into layer 2/3 of hindlimb area of the somatosensory cortex. The GRIN lens of the

epifluorescence microscope was positioned on surface of the injected site by referring to the fluorescence intensity, and then the microscope attached to skull with dental cement. The system can monitor population calcium activity from freely moving mice, and transmit data to a PC that also monitors mouse behavior with simple off-the-shelf ("web") cameras. If combined with transgenic animals expressing a genetically encoded calcium indicator, this system could also record the activity of specific cell types.

Title: 3D two-photon microscopy made simple: Rapid z-scanning with electrically tunable lenses

Authors: F. F. VOIGT, O. PFÄFFLI, M. VAN 'T HOFF, *F. HELMCHEN
Brain Res. Inst., Zurich, Switzerland

Abstract: Standard 3D microscopy methods rely on mechanical translation of the microscope objective, using either standard z-stages or piezoelectric actuators. Due to the inertia of the moving parts, such methods are not commonly employed for z-scanning rates exceeding 20 Hz. To allow faster imaging, especially for two-photon calcium imaging
of neuronal populations in vivo, optical focusing methods based on tunable optical elements are desirable. A simple and cost-effective way to achieve rapid z-scanning is the use of an electrically tunable lens (ETL) in the optical path. We will provide information on the best ways

to integrate an ETL (from Optotune) into two-photon microscopes with galvo-, resonant- or acousto-optical scanners. Depending on the performance requirements, implementations range from very simple (usually achieved by placing the ETL as close as possible to the scanners) to sophisticated setups (involving additional relay optics and optical feedback). ETLs can be used in a wide variety of imaging modes, ranging from the slow acquisition of z-stacks, essentially replacing piezo-electric actuators, to rapid (>20 Hz) multi-plane imaging or volume sweeps. Depending on the desired performance, care has to be taken to optimize the driving signal and to avoid drift effects. To this end, we have built an optical feedback module for ETLs (based on an astigmatic focus detector with a quadrant photodiode) which can be used in a two-photon microscope or as a stand-alone device. Using this system, we have characterized the dynamical properties of a range of tunable lenses, including next-generation ETLs. Such ETLs achieve step response times below 10 ms and resonance frequencies above 0.6 kHz.
Work is ongoing to combine ETL-based focusing with other microscopy methods.

Title: Optical instrumentation for simultaneous imaging and patterned photostimulation at cellular resolution in awake mice

Authors: *J. P. RICKGAUER, D. W. TANK
Princeton Univ., PRINCETON, NJ

Abstract: Recently developed methods allow optical imaging of calcium-dependent fluorescence transients at cellular resolution from populations of neurons in awake, behaving mice. For some studies, it could be valuable to complement these methods for optical detection of activity with technology additionally allowing optical perturbation of activity in patterns based on observed cellular response profiles. Here, we describe instrumentation that combines and controls two optical systems, one for high-resolution two-photon imaging and one for spatially localized two-photon stimulation. The instrument design is based on our biophysical findings

describing two-photon excitation (TPE) of channelrhodopsin-2 (Rickgauer & Tank, PNAS 106, 15025; 2009) and optical methods to generate spatially patterned TPE profiles using ultrashort pulse dispersion (Vaziri & Emiliani, Curr. Opin. Neurobiol. 22, 128; 2012).
The imaging system allows fast, high-resolution detection of green fluorescent indicator probes (e.g., GCaMP), and is designed to produce minimal collateral excitation of red-shifted opsins (e.g., C1V1). To achieve this, fsec excitation pulses from a source operating at 920+/-6nm are focused to a diffraction-limited spot in the sample plane. The spot can be scanned for either full-frame image acquisition or rapid random-access sampling using an XY scanner pair of large aperture acousto-optic deflectors pre-compensated for chromatic dispersion.
The photostimulation system is designed to allow rapid sequential excitation of red-shifted opsins at cellular resolution, and on a physiological timescale (msec), while producing minimal collateral excitation of fluorescence from green indicator probes. To achieve this, fsec excitation pulses from a second source operating at 1064nm+/-6nm are temporally focused to form a variable-diameter spot (5-20um) that can be adjusted to the projected dimension of a cell soma, and which has a thin axial TPE profile (FWHM=6um) in the perifocal region. This spot can be repositioned rapidly (>1kHz visitation rate) across the 200um square imaging field of view using galvanometer-driven mirrors.
The two optical systems are combined using a long-pass dichroic. Spatial registration and scanner synchronization are controlled using custom hardware and software written in LabView; during an experiment, visualized cells can be targeted for optical stimulation while imaging. The instrument employs a custom microscope head, toroidal projection screen, and sample stage that are designed to work with virtual reality-based behavior training in rodents (Harvey et al., Nature 461, 941; 2009).

Title: Investigating laminar specificity of neurovascular coupling using OCT angiography

Authors: *V. J. SRINIVASAN[1], A. DEVOR[2], H. RADHAKRISHNAN[3], D. A. BOAS[1], M. FRANCESCHINI[1]
[1]Martinos Ctr. / Dept of Radiology, Massachusetts Gen. Hosp. / Harvard Med. Sch., Charlestown, MA; [2]Dept. of Neurosciences, UCSD, La Jolla, CA; [3]Ctr. for Neural Engin., Pennsylvania State Univ., University Park, PA

Abstract: Depth-resolved Optical Coherence Tomography (OCT) angiography was used to investigate neurovascular coupling in the rat somatosensory cortex. In contrast to other optical microscopic imaging modalities, OCT affords sufficient penetration depth to image up to cortical layer V in the rat. We recently developed an angiography technique that enables simultaneous, depth-resolved imaging of hemodynamic changes. The goals of this study were (i) to establish theoretically and empirically that our OCT angiogram yields a depth-specific measurement of red blood cell (RBC) content under our experimental conditions, (ii) to investigate subtle timing differences in the RBC responses across cortical layers, and (iii) to characterize the RBC response across arteriolar, venular, and capillary compartments. Five Sprague-Dawley rats anesthetized with alpha-chloralose were used for these preliminary experiments. Imaging was performed through a closed cranial window during forepaw stimulation. The Spectral / Fourier domain OCT light source at 1310 nm consisted of two superluminescent diodes combined with a 50/50 fiber coupler, yielding an axial resolution of approximately 3.6 microns and a penetration depth of approximately 1 mm. Either a block stimulus paradigm (2 s or 4 s, 3 Hz) or parametric stimuli with varying stimulus frequencies (4 s, 1-5 Hz) were applied. For parametric stimuli, simultaneous surface potentials were recorded. Two-dimensional or three-dimensional scanning protocols were used to investigate laminar or compartment differences, respectively. Our data show that the hemodynamic response, as determined by RBC content, occurs earliest in layer IV, and is delayed in layers I-III and layer V, consistent with recent findings obtained using two-photon microscopy and BOLD fMRI. We observe responses (increases in RBC content) in all three vascular compartments, with the largest and earliest response found in the arterial compartment. Furthermore, our data shows virtually no evidence of “all or nothing” capillary recruitment, in agreement with earlier studies using confocal microscopy. We anticipate that these techniques we have developed will enable more detailed and comprehensive characterization of the neurovascular relationship across cortical layers than was previously possible.

Title: Real-time intracellular thermodynamics and calcium imaging upon pulsed infrared laser excitation *in vitro*

Authors: *H. A. HOLMAN[1], M. FRERCK[2], R. RABBITT[2]
[1]Dept. of Bioegineering, Univ. of Utah/ Dept Bioengineering, Salt Lake City, UT; [2]Dept. of Bioegineering, Univ. of Utah, Salt Lake City, UT

Abstract: The use of pulsed infrared lasers (IR) to stimulate neurons and other excitatory cells is thought to be primarily through non-equilibrium thermal excitation of trans-membrane proteins and lipid bilayers. Here we describe a method for imaging IR evoked mitochondrial Ca^{2+} cycling and intracellular thermodynamics. To investigate the origins of IR-evoked intracellular Ca^{2+} transients we used genetically encoded Ca^{2+} indicators (CMV-mito-GEM-GECO and G-GECO1 plasmids) in human immortal HeLa cells *in vitro*. Results provide additional evidence that pulsed IR modulates mitochondrial Ca^{2+} cycling and that this is the major mechanism responsible for fast IR phase-locked action on synaptic transmission. Confocal fluorescence and time-lapse imaging was used to track mitochondria-localized free and bound Ca^{2+} transients, and cytoplasmic Ca^{2+} transients in response to IR. Pulses of IR were delivered at ~1862nm using 200µm diameter optical fibers,100-500µs pulse widths, at a rate 1-80pps (Capella, Lockheed Martin Acculight). Low duty cycle pulsed IR generates relatively small changes in temperature (T), but substantial changes in the rate of change dT/dt. Our results show that mitochondrial Ca^{2+} cycling is particularly sensitive and implicate the uniporter mCU and exchanger mNCX as likely candidates. Energy delivered to cells by pulsed IR modulates the state of the plasma membrane currents, intracellular signaling and thermodynamics.
Temperature fluctuations can modulate thermally sensitive ion channels, while IR-evoked rates of change in temperature (dT/dt) may underlie rapid changes in plasma membrane capacitance and modulation of synaptic transmission through non-equilibrium thermodynamics. Pulsed IR also evokes controllable intracellular Ca^{2+} transients across numerous excitable cell types that persist in zero extracellular Ca^{2+}. Recent data led to the hypothesis that pulsed IR stimuli trigger uptake and extrusion of Ca^{2+} by mitochondria and that intracellular Ca^{2+} signaling underlies IR-

evoked responses. This study examines further the Ca^{2+} dynamics and intracellular temperature changes from pulsed IR in real-time.

Title: Neurophotonics: Optically controlled guidance, manipulation and stimulation of neurons

Authors: *S. MOHANTY, L. GU, B. BLACK, K. DHAKAL
Univ. of Texas, Arlington, TX

Abstract: Though photonics technologies are being used for imaging structure and function of neurons at the cellular to animal levels, it has just begun to be used to remotely manipulate, and control neuronal circuitry and activity at cellular as well as whole animal level. While new methods are being discovered to direct neuronal growth by light, precise surgery by ultrafast lasers is enabling transfection and nano-surgery of neurons. Recently, optogenetic stimulation has allowed modulation of activities of specific neuronal circuitry, which has enabled potential intervention of neurological disorders. We will discuss recent developments and work carried out in my group on Neurophotonics. These include highly efficient optical guidance of axons, ultrafast laser-assisted delivery of genes into retina, new repair and migration path of regenerated axons after laser-induced injury, and use of non-linear optogenetics for precise stimulation of neurons. Use of some of these technologies in intervention of diseases such as retinitis pigmentosa and chronic pain will also be described.

Title: An automated sleep detection and deprivation system for fruit flies

Authors: M. CHAN[1], S. GABBERT[2], H. HARMON[2], E. L. AKERS[2], J. E. ZIMMERMAN[1], A. I. PACK[1], *D. A. JOHNSON[2]
[1]Ctr. for Sleep and Circadian Neurobio., Univ. of Pennsylvania, Philadelphia, PA; [2]Pinnacle Technol, Inc., LAWRENCE, KS

Abstract: Sleep is a fundamental biological process. Insufficient sleep leads to significant, wide-reaching changes in physiology, mental acuity, physical performance and mood. Because the fruit fly (*Drosophila melanogaster*) has demonstrated conservation of pharmacological processes, neurological control and behavioral characteristics of vertebrate sleep, this model system is used to identify and investigate the genes underlying sleep behavior. We have developed a scalable, modular, and fully enclosed video-based system capable of measuring and selectively disrupting the sleep state of 160+ fruit flies in a standard commercial incubator. Video data is processed in real-time and stored locally. Experiment control and video preview along with access to x-y position, sensor information (light intensity, temperature and humidity) and real-time video feeds are available for all underway experiments via a master monitoring computer that can reside locally or remotely. Measurement of sleep bout length was similar between this system and that of a previously validated video measurement system, confirming the ability of our design to use video tracking for the purpose of detecting sleep bouts in flies. In addition to simple sleep state monitoring, the use of sleep deprivation has been shown to be a powerful technique for understanding the molecular mechanisms underlying sleep. Our system is capable of delivering real-time sleep deprivation stimuli to individual flies based on the currently observed sleep/wake state. Using this system, we measured changes in total sleep and average sleep bout duration for the 12 hours following application of individual sleep deprivation stimuli. We found a significant increase in total sleep in the 12 hours following the automated stimulus (SD) for flies as compared to a second control group which were not sleep deprived (C) ($p=0.005$, t-test). In addition, there was a significant increase ($p=0.010$, t-test) in the average duration of sleep bouts after stimulation of the SD flies compared to the C flies. The increase in sleep and the increase in average sleep bout duration are both strong behavioral indicators that the SD flies were undergoing recovery sleep, the normal homeostatic response to loss of sleep. This instrument represents the first, validated method for automatically measuring, recording and selectively depriving individual fruit flies using video-based monitoring and presents a useable solution for very large scale genetic screens requiring the simultaneous monitoring of several hundred flies.

Title: Near infrared stimulation of globus pallidus and subthalamus

Authors: M. YOO[1], H. GOO[2], H. KIM[1], M. KIM[2], S. KIM[1], *H.-I. KIM[1]
[1]Med. Syst. Engin., GIST, Gwangju, Korea, Republic of; [2]Dept. of Physiol., Wonkwang Univ. Sch. of Med., Iksan, Korea, Republic of

Abstract: Near infrared stimulation (NIRS) is an emerging technique to have the potential of replacing the conventional electrical stimulation method. The efficacy of NIRS in evoking action potentials has been demonstrated in different nervous tissues. However, few studies were performed to stimulate the globus pallidus (GP) and subthalamic nucleus (STN), frequent targets of deep brain stimulation for Parkinsonism.
Male Sprague-Dawley rats were randomly divided into three groups: GP stimulation (n=11), STN stimulation group (n=6), and sham-operated group (n=5). After introducing the optrodes sterotactically into GP or STN, we stimulated neural tissue for 2 minutes with continuous near infrared light of 808 nm varying the radiant exposure from 10 mW to 40 mW, and its effect was investigated with extracellular recording before, during, and after NIRS. Sham-operated group was not exposed to NIRS with implanted optrode. Recorded spikes were analyzed with MATLAB-based spike sorting program.
NIRS was found to elicit the excitatory response in 8/11 (73%) and inhibitory response in 3/11(27%) for GP stimulation group whereas NIRS predominantly evoke inhibitory response in 5/6 (83%) for STN stimulation group. Stimulation-response pattern was dependent on the intensity of radiation exposure. Only radiation above 30mW could elicit the statistically significant neural response ($p<0.05$).
It is concluded that NIRS can induce local neural response in excitatory or inhibitory pattern with more than 30 mW intensity. GP showed excitatory responses more frequently and STN predominantly showed the inhibitory responses.

Title: Chronic multiphoton microscopy of entire visual cortical columns in awake mice using microprisms

Authors: M. WOLFEL[1], G. GOLDEY[2], N. GILFOY[1], R. N. S. SACHDEV[3], D. A. MCCORMICK[3], C. REID[5], M. ANDERMANN[5], *M. J. LEVENE[1,4]
[1]Yale Univ., NEW HAVEN, CT; [2]Nothwestern Univ., Boston, MA; [3]Neurobio., [4]Neurol., Yale Sch. of Med., New Haven, CT; [5]Neurobio., Harvard Med. Sch., Boston, MA

Abstract: Multiphoton microscopy of cortical brain activity has largely been restricted to superficial layers. Thus, conventional in vivo imaging techniques are not capable of monitoring activity of neurons across all cortical layers. Recent, advanced multiphoton methods have enabled imaging from as deep as layer 5, but only in sparsely labeled cortices and with relatively low resolution in the z axis. Further, these methods currently cannot provide simultaneous

recordings from neurons in superficial as well as in deeper layers.
We achieved simultaneous in vivo multiphoton microscopy of neuronal activity throughout all cortical layers using glass microprisms. A prism is inserted chronically into the neocortex such that it reflects a vertical image plane containing all 6 layers onto the horizontal image plane at the brain surface. The imaging face of the prisms used has side lengths of 1.0 mm or 1.5 mm, enough to span the entire neocortical depth. The calcium indicator dye GCaMP3 is expressed in various types of neurons, either using transgenic animals, or through GCaMP3 viral transduction. We successfully imaged neuronal activity in acute preparations, and in chronic preparations for several weeks after surgery. Simultaneous spontaneous and stimulus-evoked activity in hundreds of active neurons in layers 2/3, 5 and 6 could be recorded across days in primary visual cortex of awake, head-restrained mice.
Electrical recordings of neuronal spiking and local field potentials were obtained in order to evaluate the impact of the prism implant on electrophysiological measures of neural activity. Whisker-evoked responses could be recorded in barrel field somatosensory cortex in anesthetized, head-restrained mice within minutes after prism insertion, and for weeks thereafter. By combining Cre-dependent fluorescence expression with transgenic mice that express Cre in a cell type- or layer-specific manner, we can examine the response properties and correlated activity of identified neural populations across all layers of neocortex. We conclude that the simultaneous imaging of neuronal activity throughout the depth of the cortex is readily available through the use of microprisms.

Title: Wide-field multiphoton imaging of cellular dynamics in thick tissue by temporal focusing and patterned illumination.

Authors: *O. DUPONT-THERRIEN[1], B. AUBÉ[2], P. DE KONINCK[2], D. CÔTÉ[2]
[1]Ctr. De Recherche Univ. Laval Robert-Giffard (CRULRG), Univ. Laval, Quebec, Canada; [2]Ctr. De Recherche Univ. Laval Robert-Giffard (CRULRG), Univ. Laval, Quebec, QC, Canada

Abstract: To understand circuit function, strategies to monitor the activity of a large number of neurons at high speed in vivo are necessary. Optical methods based on beam scanning, such as two-photon microscopy, have the capacity to access neurons within surface layers of the brain, but are less suitable for high speed network imaging. Wide-field temporal focusing is a technique that provides optical sectioning for imaging without the need for beam scanning. However, illuminating over large areas greatly reduces the photon density which limits the technique applicability to small regions, precluding functional imaging of cellular networks. Here, we report the first use of temporal focusing combined with spatial light modulation to create a fast imaging modality for functional neuronal activity measurements. Our strategy combines beam shaping and temporal focusing of amplified pulses for fast imaging of cells from the central nervous system in acute slices. We show multiphoton video-rate imaging with an optical sectioning under 10 μm at 800 nm, leading to imaging of calcium dynamics of multiple cells simultaneously in brain slices. It is also shown that out-of-focus fluorescence background rejection by temporal focusing of amplified pulses leads to an improved signal-to-background ratio when monitoring the spontaneous variations in free calcium ion concentration in cells from neuronal acute slices. With beam shaping, addressing of individual neurons is achievable and makes it possible to combine the sensing of activity with optical stimulation for analysis of network communication. The combined fast imaging and optical sectioning capabilities of this approach open the way to also probe voltage fluctuations within neural networks in brain slices or in vivo over large regions simultaneously.

Title: Head probe for combined near-infrared spectroscopy and electroencephalography

Authors: P. GIACOMETTI, *S. G. DIAMOND
Thayer Sch. of Engin., Dartmouth Col., Hanover, NH

Abstract: We present a new noninvasive head probe for concurrent measurement of neural and hemodynamic signals related to human brain function. This device is needed to support neuroimaging research that aims to advance our understanding of the neurovascular relationship. Multimodal research on the neurovascular coupling is important to fundamental neuroscience and biomedical research on neurovascular diseases.
This head probe combines near-infrared spectroscopy (NIRS) optodes and electroencephalography (EEG) electrodes into a single cap with whole-head coverage. It is designed with a low profile and assembled without ferromagnetic materials for compatibility with magnetic resonance imaging (MRI) and magnetoencephalography (MEG). The design accommodates normal head shape variations and a wide range of head sizes. Standard EEG 10-10 electrode positioning and 10-5 optode placement layout are used to facilitate clinical interpretation of results. Important evaluation criteria for the probe design are NIRS and EEG data quality, reduction of motion artifact, accuracy of electrode and optode positioning, electrical and optical coupling, ease of use, and durability.
The current prototype of the NIRS-EEG head probe has been successfully built and tested. It contains 65 electrodes and 64 optodes. Its design is based on an expandable linkage structure that follows the primary contours of the scalp. Electrodes serve as linkage joints to allow size expansion to fit the desired head size while maintaining equidistant spacing. Electrodes placed at the inion, nasion, preauricular, and central fiducial positions determine the location of all optodes and electrodes by mechanically following the 10-10 coordinate system and ensuring accuracy in the head probe positioning.
An electrode positional accuracy test was performed on 13 subjects to evaluate the head-surface positioning accuracy. Measurements were obtained for test-retest accuracy and with respect to the geometry of the 10-10 system. The probe had a mean positional error of 1.9 (±0.6mm) and an error with respect to 10-10 of under 0.5%.

a) NIRS-EEG head probe, b) standard deviation from mean position [mm], c) root-mean-squared error of line segment [% of total arc length]

Title: A framework for remote voxel-level access to distributed neuroimaging data

Authors: *B. N. NICHOLS[1,2], R. F. DOUGHERTY[4], L. T. DETWILER[1], G. SCHAEFER[4], R. J. FRANK[2], J. F. BRINKLEY[1,3], B. A. WANDELL[4], T. J. GRABOWSKI[2]
[1]Biomed. Informatics and Med. Educ., [2]Integrated Brain Imaging Ctr., [3]Biol. Structure, Univ. of Washington, Seattle, WA; [4]Ctr. for Cognitive and Neurobiological Imaging, Stanford Univ., Stanford, CA

Abstract: Scientific discovery about the human brain will be accelerated by neuroinformatics services on the programmable web. Just as bioinformatics databases provide services for molecular data, a scalable service-oriented framework is needed to take advantage of the large number of human neuroimaging data sets now available online. We have developed a specification, NIQuery, for remote access to observation-level data in distributed and heterogeneous image-specialized databases. NIQuery integrates emerging open source standards for metadata description, access & query, and provides investigators with computational access to remote voxel-level data.
The protocol supporting this functionality consists of: 1) a persistent Session object that wraps databases (e.g. XNAT[1], NIMS[2], Allen Institute[3]), exposes the NIQuery application programming interface, and serves objects and requests; 2) a Query object that provides a mechanism to interrogate databases with user defined and/or predefined web-accessible queries; 3) a Data object conforming to a supported 'image' data model (e.g., DICOM, NIfTI, etc.) that provides a mechanism to return pixel data to an application; and 4) a Workflow object through which a server provides a computational service on a Data object. A registry service (www.niquery.org) provides an index of available NIQuery servers, as well as the query, data, and workflow objects available on each server.
NIQuery enables client applications to discover shared neuroimaging data using metadata-level distributed queries and then execute image processing workflows on discovered data at their source, on a cached copy in the cloud, or locally. A sample implementation of this framework involves exporting a snapshot of XNAT and NIMS databases into XCEDE XML files, indexing the snapshots with the NIQuery registry service, and remotely calculating quality control metrics on resting-state fMRI data. These informatics tools will support agile exploration and reuse of open access neuroimaging data.

Abstract: In the past five years the Neuroscience Information Framework (NIF) has provided increasing data integration services to the Neuroscience community. NIF currently provides data integration at many levels, including information in databases from over 150 resources making NIF the largest collection of Neuroscience information on the web. In addition, NIF provides Entrez LinkOut broker services to more than 30 resources. This service allows these resources to have data links from NCBI and PubMed. To help in accomplishing these tasks, at the resource interoperation level, NIF utilizes and continues to enhance DISCO, an extensible framework for managing the integration of data from disparate Internet resources.
DISCO uses a proprietary format specification written in XML to define how and when the information is retrieved from each resource. DISCO uses this information to build a dynamically robust federated data warehouse environment. In addition, DISCO includes other components

within NIF that operate on this data to index, semantically map, interrelate and link this content to resources in the federation as well as external national resources such as NCBI. NIF makes available all resource information via several applications at the NIF portal (http://neuinfo.org).A key component of the DISCO implementation within NIF is a comprehensive management dashboard that allows curators to coordinate all portions of the data ingestion and integration process. We will show how this information pipeline is currently implemented in the

NIF.

Title: Services and workflows to share and analyse multielectrode array data on the CARMEN web platform

Authors: *C. D. INGRAM[1], E. SERNAGOR[1], M. WEEKS[2], M. JESSOP[2], J. AUSTIN[2], L. S. SMITH[3], T. JACKSON[2]

[1]Inst. Neurosci, Newcastle Univ., Newcastle upon Tyne, United Kingdom; [2]Computing Sci., York Univ., York, United Kingdom; [3]Computing Sci. & Mathematics, Stirling Univ., Stirling, United Kingdom

Abstract: Developments in multielectrode arrays (MEAs) now permit simultaneous recording of up to several thousand channels of data. Sharing and analysing these rich data sets can provide considerable opportunity for discovering the properties of neural networks. CARMEN (www.carmen.org.uk) is a virtual (web-based) collaboration environment open to all neuroscientists for the analysis and management of electrophysiological data. A number of groups are using CARMEN to share MEA data derived both from established networks (eg retina) and from evolved networks (eg hippocampal cultures), and here we present some of features of the CARMEN platform that facilitate sharing and analysis of MEA data. A key function of CARMEN is the ability to undertake analysis using community-derived software, including algorithms to explore network properties derived from MEA data. CARMEN provides the infrastructure to allow software code to be deployed, via a lightweight wrapping process, as interactive services that run on the cloud resource. Working on files of up to 4096 channels, analysis routines deployed on CARMEN enable visualisation of activity patterns in a variety of formats, including movies of heat maps, and user groups have deployed a variety of bespoke analysis software. Whilst this software can be configured to run on proprietary data formats, we have developed a common format (NDF) and deployed a number of services in CARMEN to convert MEA files into NDF. By supporting users to configure their code to run on NDF, analysis routines can achieve universal format compatibility. NDF supports ‘n’ channels of recording with options to visualise and select specific channels for analysis. Undertaking analysis on CARMEN using NDF offers many benefits, including the efficient re-use of software applications, the ability to compare processing algorithms, and access to hardware resource for high intensity computing tasks. This has particular advantages when scaling up for analysis of MEA data, or when combining analysis services in an orchestrated processing pipeline, or workflow. To facilitate this multi-step analysis we have developed a workflow generation and execution system which satisfies the requirements relating to the CARMEN cloud execution model and the NDF data format. The CARMEN Workflow Tool is Java-based and supports both data and control flow, and allows parallel execution of services. The complete workflow tool consists of a graphical design tool, a workflow engine, and access to a library of CARMEN services and common tasks in analysing MEA data. We will present a number of analysis algorithms and workflows that can extract key features of network activity from MEA data.

Title: Making the NeuroNames brain structure ontology available in multiple formats

Authors: *D. M. BOWDEN[1], E. SONG[2]
[2]Natl. Primate Res. Ctr., [1]Univ. of Washington, Seattle, WA

Abstract: NeuroNames began twenty years ago as a standard nomenclature for classical structures of the primate brain. We have gradually expanded it with the goal that it become: 1) a comprehensive neuroanatomical nomenclature, 2) in multiple languages, 3) with detailed descriptions of relations among brain structures, 4) in the species most studied by neuroscientists. For ten years NeuroNames has provided the ontological structure for BrainInfo, a portal to neuroanatomy on the Web (http://braininfo.org).
The purpose of this project is to make the standard terminology and definitions of NeuroNames more accessible to operators of large databases who need a standard nomenclature and ontology for indexing and interoperability of massive neuroscientific data storage and retrieval systems. Important features of NeuroNames include:
--- A standard vocabulary of unique, commonly used, short, pronounceable English terms for some 3,000 structures found in the brains of humans, macaques, rats or mice.
--- Bottom-up definitions of most structures indicate their location relative to classical structures in brain atlases of the four species, the method by which each structure is defined (stain for Nissl substance, myelin, a neurotransmitter, a receptor, expression of a gene, etc.), and which of the four species possess it.
--- Top-down modelling (parent-child relations) of each structure in multiple hierarchical models, such as the NeuroNames' Classical Brain Hierarchy (structures grouped by proximity), a Functional Hierarchy (based on Swanson's grouping by function and connectivity as well as proximity), neurochemical hierarchy (e.g., grouped by neurotransmitter), etc.
--- 12,000 synonyms: English, French, German, Italian, Indonesian, Latin, Russian, and Spanish
The NeuroNames standard nomenclature is or will be available in:
--- Excel and XML at http://braininfo.rprc.washington.edu/Nnont.aspx
--- OWL at website of Neuroscience Information Framework (NIF)
--- UMLS as a source vocabulary of the Unified Medical Language System of the National Library of Medicine.

Title: A distributed light-weight database for the organization of electrophysiological data

Authors: *B. R. LJUNGQUIST[1], S. GERHARD[2], A. J. JOHANSSON[1], J. SCHOUENBORG[1], M. GARWICZ[1]
[1]Lund Univ., Lund, Sweden; [2]Inst. of Neuroinformatics, Uni/ETH Zurich, Zurich, Switzerland

Abstract: When sharing neural data, both electrophysiological and image data as well as other forms of data, there are some requirements which should be met: 1) Different acquisitions system have different data formats for offline and real time data, which needs to be accessed and processed in a common way by applications; 2) Data need to be stored in a database system directly in connection with the recording facility in order to facilitate data organization and sharing; 3) Data must be accessible for data-intensive applications. In this work, we present a distributed database system which allows for storing and analysis of electrophysiological data in real time simultaneously across multiple locations, addressing the problems identified above. The database is light-weight as it stores only the electrophysiological data itself, and may be complemented by databases of meta data, whose format is more likely to change from experiment to experiment and may not be easily standardized across labs. We also present a case study which shows how data both from simulations and experiments, the latter taken form

multiple types of acquisition systems, can reside in the same data base and be shared in real time, thus allowing for direct and parallel computational analysis of electrophysiological data.

Title: Neuroinformatics database (NIDB): a portable database for storage, pipeline processing, and sharing of neuroimaging data

Authors: G. A. BOOK[1], *P. SKUDLARSKI[1,2], M. STEVENS[1,2], G. PEARLSON[1,2]
[1]Hartford Hosp. / IOL, Hartford, CT; [2]Psychiatry, Yale Univ. Sch. of Med., New Haven, CT

Abstract: An OHBM article from 2001 described an estimated 1500 studies collected per year globally[1]. Now, a single MR scanner can easily be used to collect 1500 studies in a year. This capacity coupled with an increasing number of imaging centers creates a huge amount of neuroimaging data and presents a challenge to storing and sharing. Databases including xNAT, COINS, and Redcap are available to the neuroimaging community. xNAT can be hosted on site but requires a significant time investment to install and configure and as of version 1.4 does not have series level search or processing. COINS is comprehensive, but allows only remote access to neuroinformatics data and access is granted by invitation only. Redcap is IRB compliant, but does not store neuroimaging data. We propose to fill the gaps in existing databases by creating a data-up style system with these features: a) local hosting of data b) series level searching and processing c) ease of use/install d) automatic pipeline processing e) easy sharing of data.
Methods: NIDB defines the primary objects in the database as subjects, studies, and series. Subjects can belong to multiple projects and can have multiple studies, independent of project. Studies can have multiple series of a single modality. Each subject is randomly assigned a unique ID (S1234ABC). This string format allows 175 million unique IDs. A person is unique based on their name, DOB, and gender. DICOM data is parsed and stored in NIDB within 1m after data is uploaded from the MRI scanner, and QA parameters are calculated within 5m.
Results: The development site has collected 10,010 MRI studies, 1,041 EEG studies, and smaller numbers of other modalities in 9 years. An additional 2000 MR studies from other sites have been stored in NIDB. We currently host 118,000 MRI series, and 22,200,000 files. Average

search times for 20 series: 0.05s, 2000 series: 0.5s, and 15000 series: 1.5s. Import of DICOM data from the MR scanner requires no human intervention, while importation of PAR/REC and EEG requires some manual processing. An audit of the database found no orphaned data and 117 file count errors due to unique MR sequences.
Discussion: Our open-source database met the requirements set forth, with fast, granular access to data, allowing highly specialized automated pipeline processing of data. We felt NIDB filled the gaps left by other databases. Data from existing databases is easily imported into NIDB and the system provides simple search, statistics, and pipelining. Additionally, the structure of NIDB allows easy packaging of data for export to projects such as 1000 functional connectomes.

Title: Neuromorpho.org - What's next?

Authors: *R. PAREKH, K. SUBRAMANIAN, J. SAXENA, S. POLAVARAM, G. A. ASCOLI
Ctr. for Neural Informatics, Structures and Plasticity, George Mason Univ., Fairfax, VA

Abstract: NeuroMorpho.Org was introduced to the neuroscience community in 2006 as a collection just shy of 1,000 digital reconstructions of 3D neuron morphologies. Six years later, the repository now contains nearly 8,000 curated reconstructions, reflecting over 200,000 human tracing hours from 19 species, 89 cell types, 59 brain regions, and 86 laboratories worldwide. Millions of downloads of these shared digital reconstructions continue to result in new published discoveries from morphometric and stereological analyses, statistical quantification of potential synaptic connectivity, computational models of axonal and dendritic development, and biophysically realistic electrophysiological simulations of neuronal activity. The repository also maintains a literature database providing a comprehensive coverage of publications that report 3D digital reconstructions.

The steady increase in the number of reconstructions in the repository reflects a change in attitude of authors towards data sharing. Furthermore, advancements in high-throughput data acquisition and automated digital reconstructions will result in an unprecedented wealth of data. As a consequence, NeuroMorpho.Org is on a projected trajectory of including over 25,000 reconstructions by 2013. Reaching this critical mass will shift scientific investigations to the next phase of large-scale comparative studies across metadata categories. Combining metadata and morphometry searches may allow more effective identification of relevant data.
The expected data upsurge will also expand the database scope, requiring appropriate representation of multiple neurons within the same circuit and of time series. Both of these aspects, the relative spatial arrangement of different reconstructions and the temporal sequence of the same reconstruction, will dictate alterations of the database infrastructure, as well as distinct curation and annotation protocols.
This poster is intended as a platform to discuss, design, and stimulate feedback on future NeuroMorpho.Org directions with users (such as computational modelers), data contributors, software developers, and anyone interested in digital reconstruction of neuronal morphology. Community interaction has integrated NeuroMorpho.Org into a synergistic "ecological niche" around digital reconstructions that includes resources and tools for data acquisition, 3D visualization, morphometric analysis, and biophysical modeling. NeuroMorpho.Org plays an important role in the curation, annotation and standardization of reconstruction data and can contribute to establishing standards and norms for data description in the field.

Title: The zebrafish neurophenome project (znp) database: Developing use cases and terminology standardization

Authors: *E. J. KYZAR[1,2], J. CACHAT[2], S. GAIKWAD[2], J. GREEN[2], A. ROTH[2], C. COLLINS[2], A. STEWART[2], A. V. KALUEFF[2,3]
[1]New Orleans, LA; [2]Tulane Univ., New Orleans, LA; [3]Zebrafish Neurosci. Res. Inst. (ZENEREI), Slidell, LA

Abstract: The Zebrafish Neurophenome Project (ZNP) database (ZNPdb) was developed to complement the available repositories for zebrafish genetic information by providing a dynamic open-access data repository for behavioral and related physiological data obtained from zebrafish experiments (Kyzar et. al. 2012). Currently, the ZNPdb represents the most comprehensive curated collection of results from zebrafish neurobehavioral experiments. As of May 2012, it contains over 4,500 experimental results, from over 75 unique physiological and behavioral tests and 330 different drug treatments, comprehensively covering published zebrafish literature. The ZNPdb is available online at http://www.kaluefflab.com/znpindex.html. The ZNPdb is actively growing based on the use cases and requests from the research community. In its current state, one of the most applicable use cases is determining if a drug has been previously tested in zebrafish models, and what doses (if any) were effective. As with any novel animal model, determining this can be a painstaking process, requiring large-scale meta-analysis of published literature. However, the ZNPdb can provide insight to the drug/dose question rather quickly and easily. From the homepage, the drug or treatment of interest can be selected from the Treatment dropdown menu, and searched. This will return all entries within ZNPdb containing that treatment, along with the administration procedure, dose, and reported effects (both significant and non-significant) in respective experimental designs. Additionally, through the continued addition of zebrafish experiments to ZNPdb, we have gathered a diverse, but comprehensive lexicon of the terminology used to describe zebrafish behaviors. Within this lexicon, we have observed that the same behavior or behavioral endpoint is often labeled with similar, but variable terminologies. For example, the amount of time spent in a particular region of a testing arena could be labeled ‘time spent in X’, ‘duration in X’, ‘time in X’, ‘preference (time spent) for X’, ‘X duration’ etc, all of these referring to the same basic measurement. This observation suggests that a standardized, zebrafish behavioral ontology would be useful for the field. Given the fact that ZNPdb has already collected most lexical variations, our lab has recently initiated efforts to create zebrafish behavior ontology, the Zebrafish Behavioral Phenotype Ontology (ZBPO). Upon completion, ZBPO will be made open-source and available to the community (via ZIRC and NCBO) for future research and integration with larger biomedical ontologies.

Title: A linked open data resource for the neurosciences: The Neuroscience Information Framework's (NIF) unified semantic framework and associated tools for integration and utilization of biomedical data and resources

Authors: *J. S. GRETHE[1], A. BANDROWSKI[1], J. CACHAT[1], A. GUPTA[2], F. IMAM[1], S. LARSON[1], L. MARENCO[3], P. MILLER[3], G. SHEPHERD[3], M. MARTONE[1], N. I. F. CONSORTIUM[1]

Abstract: Neuroscience, as with other biological sciences, has become a data intensive science where new insights and discoveries are critically dependent on researchers ability to integrate and synthesize related biological data. Neuroscience is perhaps the most information-rich of all biological sciences. The Neuroscience Information Framework (NIF; http://neuinfo.org) was launched in 2008 to address the problem of finding and integrating neuroscience-relevant resources through the establishment of a semantically enhanced framework. To enable researchers to gain access to data and information they may not have been aware of, the NIF has deployed a discovery portal that connects neuroscientists and biomedical researchers to available resources. These sources include the: (1) NIF Registry: A human-curated registry of neuroscience-relevant resources; (2) NIF Literature: A full text indexed corpus derived from the PubMed Open Access subset as well as an entire index of PubMed; (3) NIF Database Federation: A federation of independent databases that enables discovery and access to public research data, contained in databases and structured web resources (e.g. queryable web services) that are sometimes referred to as the deep or hidden web. Over the past year, NIF has continued to grow significantly in content, providing access to over 4800 resources through the Registry, and more than 160 independent databases in the data federation, making NIF the largest source of neuroscience information on the web.
To further enable the utilization of this vast collection of information, the NIF is applying semantic web technologies to its holdings. By defining a set of standards and best practices for describing and representing data, semantic web and linked data technologies eliminate the barriers between database silos and foster the evolution of the Web into a Web of data. Such technologies are being successfully applied as integration engines for linking data and information in many domains. The publication of this content relies on a coordinated suite of tools and infrastructure that manage the integration of data from disparate Internet resources. In addition, the semantic underpinning for this linked data is NIF's comprehensive ontology (NIFSTD) that covers major domains in neuroscience, including diseases, brain anatomy, cell types, subcellular anatomy, small molecules, techniques and resource descriptors. Exposing NIF's content as Linked Open Data will enable further integration with the growing amount of information available from the linked open data cloud - thereby providing a much richer resource for the neuroscientist.

Abstract: The International Neuroinformatics Coordinating Facility (INCF, http://incf.org/) Digital Atlasing Program is working towards a digital atlasing framework that will make multidimensional data of the rodent brain more widely accessible and usable to the research community (Hawrylycz et al, 2011, *PLoS Comput Biol* 7[2]: e1001065. doi:10.1371/journal.pcbi.1001065). The framework requires standard spatial reference systems (principally Waxholm Space, WHS) and a supporting data sharing infrastructure (Digital Atlasing Infrastructure, DAI); each of which is the main focus of an Atlasing Task Force. User data are primarily shared through atlas hubs, specialized servers available as part of the infrastructure or that may be installed and managed locally. Hubs register users' data to a spatial reference system, publish the data and services with INCF Central and share data via web services. At this time, the focus of both groups is on integrating image registration workflows to the underlying infrastructure with the aid of metadata, provenance, and ontology standards. Data sharing use cases drive our workflow development. At this time, we are focusing on 2D

brain slice images (sampling varies from sparse to densely sampled). The goal is to create tools, recommendations, and standard operating procedures to aid in the registration of data to a known standard atlas space and creation of new atlas hubs. With workflows that allow the creation of atlas hubs, new datasets will be able to be queried and compared to data in other atlas hubs, such as EMAGE and Allen Brain Atlas.
The two task forces are working on multiple related project areas, including:
•Production of registration fiducials and landmarks
•Standards for registration transformations
•Data management and handling
•Metadata
•Provenance
•Atlas hub in a Box
•WHS for the rat
•PONS pan mammalian delineations of WHS dataset
These areas are either needed to integrate other components with the INCF DAI, or are integrated with the infrastructure as they are developed.
This program welcomes input from the community, and requests expert recommendations in these project areas. Please contact any author for more information.
This work was conducted within the WHS and DAI Task Forces of the INCF Program on Digital Brain Atlasing.

Title: Resting-state fMRI determination of optimal target locations for non-invasive brain stimulation

Authors: *F. S. SALINAS, S. NARAYANA, L. JIMENEZ-CASTRO, P. T. FOX
Res. Imaging Inst., UTHSCSA, San Antonio, TX

Abstract: Resting-state fMRI (rs-fMRI) covariance patterns reflect inter-regional functional connectivity (e.g. resting-state networks (RSNs)). Applying independent components analysis (ICA) to these datasets provides a set of archetypal independent components (ICs), which are similar in appearance to both resting-state and task-dependent data. We, therefore, propose the use of rs-fMRI to determine the optimum site of stimulation for non-invasive brain stimulation protocols_i.e. repetitive transcranial magnetic stimulation (rTMS). We demonstrate this approach in the dorsolateral prefrontal cortex (DLPFC), a brain area connected to subgenual cingulate (SGC)_with both locations being implicated in the neural circuitry of depression via the default mode network (DMN).
rs-fMRI was acquired in human (N=20) and non-human primates (NHP; N=11) using previously developed rs-fMRI acquisition protocols. The rs-fMRI group datasets were (separately) pre-processed and analyzed with the FMRIB's FSL toolkit. ICA was performed on each group's rs-fMRI dataset using FSL's MELODIC program with multi-subject temporal concatenation (#ICs=20). The SGC nodes identified from the group ICAs were then used for region-seeded analysis (RSA) with regression analysis performed using the general linear model in FSL's FEAT program, resulting in the optimized DLPFC target site for SGC connectivity. We then applied suprathreshold rTMS (at 10 Hz) to each group's DLPFC site during positron emission tomography (PET) to demonstrate successful activation of the SGC. All procedures were performed with institutional approval for both the human and animal studies.
We successfully localized the DLPFC node connected to the SGC in both human and NHP groups using the ICA/RSA approach and delivered rTMS to the optimized target site (in human and NHP experiments), producing remote network modulations in the SGC_i.e. non-invasive, efficient delivery of a depression therapy. The rs-fMRI targeting approach has great potential since task-dependent targets are difficult to obtain in animal models and patient groups.

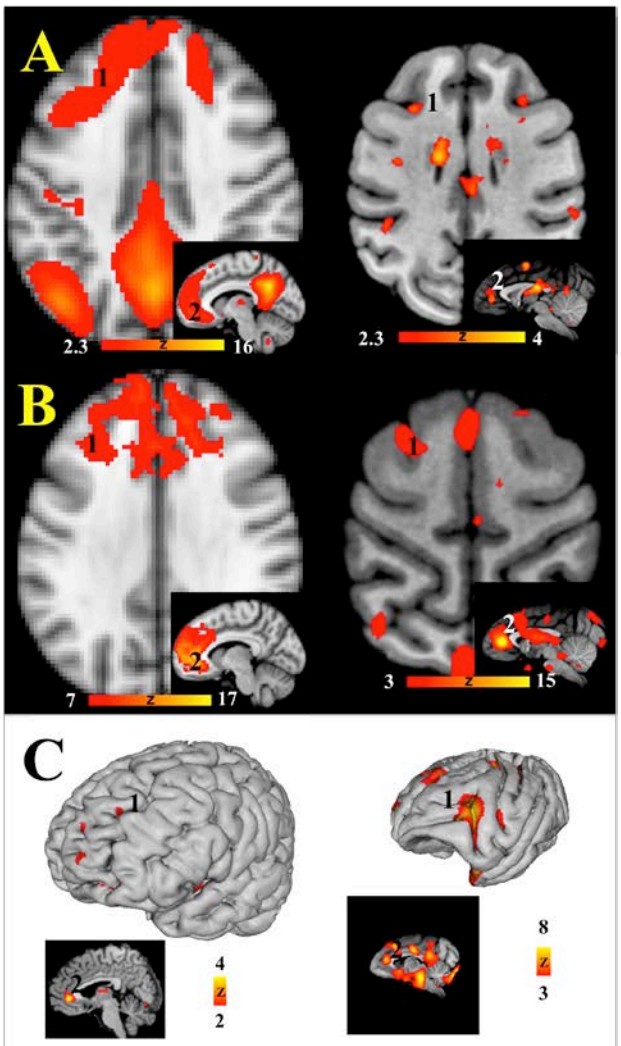

Figure 1. ICA/RSA Analyses and rTMS/PET application to DLPFC. **A.** The default mode network (DMN) IC is shown for the group ICA in humans (left) and baboons (right). **B.** Region-seeded connectivity from SGC (label #2) to DLPFC (label #1) for a single human (left) and a single baboon (right). **C.** TMS/PET brain activations from targeting the DLPFC node of the DMN for humans (left) and baboons (right). Each image shows the DLPFC target location (#1) and the SGC node (#2).

Title: Model-free reconstruction of excitatory neuronal connectivity from calcium imaging signals

Authors: *O. STETTER[1,2,3], D. BATTAGLIA[1,3], J. G. ORLANDI[4], J. SORIANO[4], T. GEISEL[1,2,3]

Abstract: A systematic assessment of global neural network connectivity through direct electrophysiological assays has remained technically infeasible, even in dissociated neuronal cultures. We introduce an improved algorithmic approach based on Transfer Entropy to reconstruct approximations to structural connectivity from network activity monitored through calcium imaging. We focus in this study, as a first step, on the inference of excitatory synaptic links. Based on information theory, our method requires no prior assumptions on the statistics of neuronal firing and neuronal connections.
The performance of our algorithm is benchmarked on surrogate time series of calcium fluorescence generated by the simulated dynamics of a network with known ground truth topology. We find that the functional network topology revealed by Transfer Entropy depends qualitatively on the time-dependent dynamic state of the network (bursting or non-bursting). Thus by conditioning with respect to the global mean activity, we improve the performance of our method. This allows us to focus the analysis to specific dynamical regimes of the network in which the inferred functional connectivity is shaped by the underlying excitatory connections, rather than by collective synchrony.
Our method can discriminate between actual causal influences between neurons and spurious non-causal correlations due to light scattering artifacts, which inherently affect the quality of fluorescence imaging. Compared to other reconstruction strategies such as cross-correlation or Granger Causality methods, our method based on improved Transfer Entropy is remarkably more accurate. In particular, it provides a good reconstruction of the excitatory network clustering coefficient, allowing for discrimination between weakly and strongly clustered topologies.
Finally, we present the applicability of our method to real recordings of in vitro cortical cultures.

We demonstrate that excitatory connections in these networks are characterized by an elevated level of clustering compared to a random graph (although not extreme) and can be markedly non-local.

Title: Integrating brain connectivity data from multiple sources with the nif platform

Authors: *A. GUPTA, A. E. BRANDOWSKI, S. LARSON, A. GUPTA, V. ASTAKHOV, C. CONDIT, X. QIAN, M. E. MARTONE
UCSD, LA JOLLA, CA

Abstract: Brain connectivity refers to a pattern of anatomical links ("anatomical connectivity"), of statistical dependencies ("functional connectivity") or of causal interactions ("effective connectivity") between distinct units within distinct brain regions. Brain connectivity can be studied at multiple spatial scales; individual synaptic connections that link individual neurons, networks connecting neuronal populations, brain regions linked by fiber pathways - are all valid ways of studying the local and global properties of the connectivity network. Over the last decade, significant research effort has been devoted to the construction, analysis and comparative studies of the graph-theoretic properties binary directed anatomical network, the weighted undirected functional network and the weighted directed effective network. However, no generic, publicly accessible platform has been developed so far for integrating and analyzing connectivity information. The Neuroscience Information Framework (NIF), with its ability to store large, heterogeneous sets of connectivity information, provides the first platform of this nature. In addition to storage and semantic search abilities, the NIF platform now provides an analysis layer that combines NIF's software with 3rd party tools to perform different kinds of analysis. To demonstrate this, we have performed connectivity analysis by integrating mammalian brain connectivity data sets from partonomic relationships in the Neurolex semantic data store, the BrainMaps Atlas, the Temporal Lobe Atlas, the CoCoMac Project, ABCD for avian brains, BAMS and the functional data from the UCLA Multimodal Connectivity Database. The system

reconciles the variation of nomenclature across these data sets by mapping brain region names into the NIFSTD ontology. The user of the system can create different views of the network by selecting metadata properties like organism and technique, the spatial scale of brain structures based on the ontological hierarchy of anatomical structures, network node properties like betweenness and closeness centrality, and network edge properties such as strength of connection and edge-betweenness properties. The network features like measures of resilience and modularity are precomputed every time the system gets updated with new data sets, thus enabling a user to explore any part of the network by features through a simple query interface created for exploring connectivity information. However, users may also compute these functions on the fly using the feature library built from the Brain Connectivity Toolbox, and estimate the statistical bias of the analyses.

Title: AntibodyRegistry.org & Domeo: A toolset for robust identification and linking of specific antibody catalog information to the scientific literature.

Authors: P. N. CICCARESE[1,2], *T. W. CLARK[1,2,3], A. BANDROWSKI[4], V. ASTAKHOV[4], J. S. GRETHE[4], M. MARTONE[4]
[1]Neurol. Dept., Massachusetts Gen. Hosp., Cambridge, MA; [2]Harvard Med. Sch., Boston, MA; [3]Sch. of Computer Sci., Univ. of Manchester, Manchester, United Kingdom; [4]Univ. of California San Diego, San Diego, CA

Abstract: Repeatability of experiments is undermined by the lack of pointers to appropriate current, and specific, descriptive information about reagents such as antibodies, in published literature. The Neuroscience Information Framework (NIF; http://neuinfo.org) and the MIND Informatics group at Massachusetts General Hospital have joined forces to build a set of tools that can be used to address this pressing need.
The NIF Antibody Registry (AR, http://antibodyregistry.org/) is a database of over 890,000 individual antibody records, covering almost 80% of the commercial antibodies used in Journal

of Comparative Neurology articles over the last 5 years. AR links these published articles with the related reagent-specific descriptors, including vendor catalog identifiers. The AR is searchable by the general NIF search engine, accessed from a Web browser or through a web service API. Individual records can be added and edited by members through a public browser interface.
Identification and curation of antibody information from research publications poses several challenges. To meet them, NIF is working to implement a textmining-assisted (semi-automatic) curation process. When catalog numbers are listed in articles and those catalog numbers match the AR, text-mining software would detect and record the match, aligned with its location in the article's text. Curators could then evaluate the results and confirm or reject the entries. When catalog numbers are not present, information such as the clone number and the supplier can help the curator to select one or more possible registry candidates.
To efficiently enable this curation process, Domeo (http://annotationframework.org) a web application for producing and managing annotation of any online documents and document fragments, has been extended to interact with the AR. A software plug-in dedicated to antibodies was created to allow visualized, in-context annotation of the document text with an antibody match from the AR. The curator specifies which methods have been applied, on what species. A free-text comment may be attached to the annotation item. The resulting annotation can be exported in RDF format according to the Annotation Ontology [1] model, and augmenting the information natively provided by the NIF framework. As Domeo integrates with text mining services, we now aim to leverage software for recognizing catalog numbers, display the results on the document and collect curator feedback enabling the literature to be robustly linked to the reagents used therein.

Title: Behavior Informatics: Integration, sharing and mining of behavioral data, models and tools

Authors: *A. R. KOENE
Brain Sci. Inst., RIKEN Brain Sci. Inst., Wako, Japan

Abstract: Various Neuroinformatics platforms have in recent years been established to facilitate a more coherent and integrated understanding of the brain (e.g. INCF, NIF). The primary focus of most of these efforts has been a bottom-up approach focusing on neuroanatomy (e.g. Allen Brain Atlas) and high-fidelity modeling of neural ensembles (e.g. Blue Brain project). To complement these Neuroinformatics efforts we propose a Behavior Informatics platform that will focus on the accumulation and sharing of behavioral data, and related analysis tools.
Behavior Informatics will integrate behavioral information across multiple scales and disciplines to establish a clear ontology of behaviors and discover new links between behaviors at micro and macro scales.
The pillars upon which the Behavior Informatics platform will be constructed are:
1. databases of behavior observations from field/real-world observation, laboratory studies and Virtual World behavior logs (information gathering from behavior in social platforms (e.g. Second-Life) and games (MMOGs));
2. literature mining, i.e. identification of relationships between published literature on the basis of commonalities in described behavior, experimental design, analysis method or model type;
3. analysis methods for: behavior classification, identifying spatio-temporal relationships between behaviors and describing their dynamic evolution during development and execution;
4. databases of models relating to behavior initiation/selection/execution.
To connect these pillars and establish a solid platform upon which to build an integrated understanding of behavior, we propose to:
1. support development of a standardized comprehensive ontology of behavior;
2. maintain a wiki for sharing of experimental methods;
3. support/develop standards for describing experiments and observed behaviors;
4. develop improved methods for visualizing multi-scale behavioral data.
Projected benefits and primary uses of Behavior Informatics:
1. establishing new links between data from different sources, scales and disciplines;
2. identify the most important gaps in our knowledge;
3. multi-scale integration of behavior models, e.g. integration of agent based and population based behavior models, validated using rich virtual world behavior logs.
Here we present the tentative road-map for the creation of a Behavior Informatics platform.

Title: Fusion of heterogeneous neuroscience data; a method that combines a myriad of web services and the Kepler workflow engine

Authors: *A. E. BANDROWSKI[1], V. ASTAKHOV[2], A. GUPTA[3], J. GRETHE[2], M. E. MARTONE[2]
[2]CRBS, [3]SDSC, [1]UCSD, LA JOLLA, CA

Abstract: We report on progress of employing the Kepler workflow engine and service oriented architecture (SOA) to prototype application integration workflows that integrate data and web services developed by the Neuroscience Information Framework (NIF; http://neuinfo.org). One prerequisite of the scientific enterprise consists of searching for effective and useful data and resources, i.e., reagents, neuro-anatomy features, genes, or proteins. Finding relevant resources is becoming not a challenge of scarcity, but one of overabundance; in fact relevant data can be found anywhere among thousands of neuroscience-relevant information resources created by a range of information providers including, research groups, funding agencies, vendor groups, and public data initiatives.
NIF provides a graphical user interface, GUI, to locate and access ontologically aligned and semantically fused heterogeneous federated information. NIF also atomized the various functions that serve the user interface and put them out as services that can be used like “Lego blocks” to query the data, build entirely new interfaces or tools. Currently, we use Kepler to orchestrate communication among various NIF services and provide a transparent layer for data fusion. Kepler combines data and processes into a configurable, structured set of steps that helps to implement semi-automated workflows. Kepler provides a development environment with a graphical user interface for designing workflows composed of a linked set of components called Actors, which can be executed under different Models of Computation. In this work, we report on specific workflows that perform data fusion and orchestration of diverse web services. This “Brain data flow” outputs categorized counts of information from 150 data sources about brain regions. Obtaining a similar set of data from the NIF GUI, requires manually writing down result counts that are the result values for each database for each query. Kepler, unencumbered by the current configuration of the user interface can be asked to pull a different set of data from the result set, in this case the number of results, and place that into a table. This table can then be easily turned into a graphic that helps users see which databases are information rich given a particular query. In this example, Kepler loops and recovers the same set of information for all of

the brain parts and all databases, producing a massive matrix (http://www.neuinfo.org/NIF_Federated_Data_Heatmap.html).

Inst., Phoenix, AZ; [11]The Alzheimer's Dis. Neuroimaging Initiative, San Francisco, CA

Abstract: **Background:** We previously developed a Hypometabolic Convergence Index (HCI) (Chen *et al.* 2011) reflecting the extent to which the pattern and magnitude of cerebral hypometabolism in an individual's fluorodeoxyglucose positron emission tomography (FDG-PET) image corresponds to that in dementia due to Alzheimer's disease (dAD) over the entire brain volume. As magnitudes at which different brain regions are preferentially affected vary at different stages of AD, this study introduces regional HCI (RHCI), a region-of-interest based HCI to better capture such pattern and magnitude variability among various brain regions and examines its use in identifying MCI patients who are close to progression to dAD in comparison with the original HCI, MetaROI means (Landau *et al.* 2009) and Magnetic Resonance Imaging (MRI) hippocampal volume.

Methods: RHCIs for frontal, posterior cingulate/precuneus, lateral temporal, lateral parietal cortex and a combination of some of these as mean cortical were calculated for baseline FDG-PET data from 207 MCI patients enrolled in ADNI. 42 participants subsequently progressed to dAD within 24 months from baseline. RHCIs, the original global HCI and MetaROIs from left and right angular, posterior cingulate, left and right temporal, composite ROI and MRI hippocampal volume were entered into stepwise Cox proportional hazard model for prediction comparison.

Results: Using RHCI predictors, MCI patients with higher RHCIs in both mean cortical and posterior cingulate/precuneus cortex are 6.56 times (model R^2=0.45) more likely to progress to AD within 24 month, compared to 4.59 times (model R^2=0.39), 5.51 times (model R^2=0.38) or 2.73 times (model R^2=0.22) for those with either higher global HCI, higher MetaROI means in both left angular and posterior cingulate cortex or lower hippocampal volume, respectively. MCI patients who have higher mean cortical RHCI (p=2.7e-5), lower metaROI means in left angular (p=0.01) and posterior cingulate (p=0.008) cortex and hippocampal volume (p=0.004) are at even higher risk, 56.06 times (model R^2=0.69) more likely, to progress to dAD within 24 month than those who do not.

Conclusion: RHCIs, alone or in combination with other biomarkers, may help predict the subsequent rate of decline in MCI patients. The results may depend on the subject cohorts, progression time, relationship of predictors analyzed, and prediction algorithm implemented.

Title: A neuroscience gateway for high performance computing

Authors: *N. T. CARNEVALE[1], S. SIVAGNANAM[2], K. K. YOSHIMOTO[2], V. ASTAKHOV[3], A. E. BANDROWSKI[3], M. E. MARTONE[3], A. MAJUMDAR[2]

Abstract: The goal of this project is to build a Neuroscience Gateway (NSG) that will reduce administrative and technical barriers to the use of High Performance Computing (HPC) resources by neuroscientists. Similar gateways have been successfully developed for other fields such as nanotechnology, phylogenetics, bioinformatics, chemistry, weather prediction etc., and allow efficient access to HPC resources by a large number of users.

The need for an NSG emerges from the tremendous expansion of computational neuroscience in recent years, as attested by the growing numbers of articles in leading journals that report work involving computational modeling. This has motivated development of domain-specific software for parallel simulation, e.g. NEURON, GENESIS3, MOOSE, NEST, and PyNN, which in turn has enabled investigators to address increasingly complex problems such as large-scale network models and optimization or exploration of high dimensional parameter spaces. These problems require access to cyberinfrastructure resources including HPC machines, fast networks, next generation data and storage technologies and software that can create and manage complex workflow, automatically run parallel simulations, and handle transfer and retrieval of data and output. While such resources exist, administrative and technical barriers to entry remain high for neuroscientists, due to the need to write convincing allocation proposals, understand complex HPC architectures, master complex OS/software environment, optimally install simulation software, learn policies and batch system environments, manage data transfer and retrieval, and understand the remote authentication process.

The NSG will provide optimally installed parallel neuronal software, such as those listed above, on HPC resources. We expect that, following the success of other science gateways, the NSG will allow a large number of neuroscientists to easily and efficiently use these programs on HPC resources and enable, enhance and broaden computational neuroscience research and education.

Title: A strategy for reporting brain structures to promote interoperability for databases and literature

Authors: *M. E. MARTONE[1], F. IMAM[2], S. D. LARSON[2], D. BOWDEN[3], G. M. SHEPHERD[4], G. ASCOLI[5]
[1]Neurosci., UCSD, La Jolla, CA; [2]Ctr. for Res. in Biol. Systems, Univ. of California San Diego, San Diego, CA; [3]Psychiatry and Behavioral Sci., Univ. of Washington, Seattle, WA; [4]Dept. of Neurobio., Yale Univ., New Haven, CT; [5]Ctr. for Neural Informatics, Structure, & Plasticity, George Mason Univ., Fairfax, VA

Abstract: The brain is perhaps unique among major organ systems in the multiplicity of naming schemes for its major and minor regions. The brain has been divided based on topology of major features, cyto- and myelo-architecture, developmental boundaries, supposed evolutionary origins, histochemistry, gene expression and functional criteria. The gross anatomy of the brain reflects the underlying networks only superficially, and thus any parcellation reflects a somewhat arbitrary division based on one or more of these criteria. Furthermore, many of these parcellations were developed before we had the ability to image the brain in 3 dimensions, leading to many arbitrary divisions. The lack of coherence in naming schemes is major impediment in developing automated means of extracting and comparing information from databases and the literature. As we now have the capability to generate data on gene expression, regional and cellular connectivity, and functional activation on a large scale, it is time to consider a strategy for naming brain regions that is designed to work better with information systems. One of the core aims of the Neuroscience Information Framework (http://neuinfo.org) is to establish an interoperable semantic framework for searching and integrating across data contained in diverse information systems. NIF and several other influential neuroinformatics projects, e.g., Neuronames, BAMS, have worked to establish the means to translate among these different nomenclatures. Interoperability is also a key goal of the INCF Program on the Ontologies of Neural Structures (PONS). The NIF project, in collaboration with PONS, has established the Neurolex Wiki, a semantic wiki for developing a collaborative knowledge base around the core concepts of neuroscience. As part of the Neurolex, we have worked with to define a reasonable

strategy for defining brain structures that is useful for implementation within information systems like the NIF. Through work with the Neurolex and PONS programs, we describe a strategy for naming and defining brain regions that promotes interoperability of brain regions across information systems, species and spatial scales. The strategy relies on the distinction between a set of reference brain structures, defined largely from a subset of common mammalian brain structures in Neuronames and several other information sources, and parcellation schemes produced by individual authors in the form of atlases or manuscripts. The strategy does not seek to impose a standard definition of brain regions; rather, it provides a means of constructing neuroanatomical concepts in a more machine processable form.

Title: Integrating data management into the laboratory workflow using a common data API for electrophysiology

Authors: A. SOBOLEV[1], A. P. LEONHARDT[1], C. KELLNER[1], P. L. RAUTENBERG[1], *S. CARDOSO DE OLIVEIRA[2], A. V. HERZ[1], T. WACHTLER[1]

Abstract: Progress in neuroscience has lead to rapid proliferation of data. The problem of efficiently organizing and annotating this information while allowing effortless access from different platforms becomes crucial if scientists are to fully exploit recorded experimental data. At the German INCF Node (G-Node, www.g-node.org), an infrastructure for cellular and systems neuroscience is being developed to improve key ingredients of neuroscientific research: data access, data storage and exchange, and data analysis. The G-Node services provide data management in the cloud, including tools for organization, annotation, search, and backup. These services are accessed through an application interface (API), which supports a common data model for electrophysiology and flexible data annotation. Native client libraries in commonly used programming languages, including Matlab and Python, enable researchers to perform

computations in familiar analysis environments while retaining the advantages that cloud storage entails. Thus, scientists may select whatever technology is most suitable for their current research with their data being available at all times and from all locations. The interface also features powerful search and query capabilities from simple full-text search to specialized query and filter mechanisms such as data slicing or recording channel selection. Collaborative research is facilitated by fine-grained data sharing mechanisms. Moreover, all the changes made to any object in the system are being tracked. Thus, scientists can to go back in time to any revision, which makes the reproduction of individual analysis steps effortless and transparent.
Using the G-Node tools and services, data organization and data exchange is easily integrated into the day to day laboratory workflow, facilitating scientific progress and reproducible research.

Title: The neural systems language: Systematic and unambiguous description and communication in connectomics and neuroinformatics

Authors: *R. A. BROWN, L. W. SWANSON
Biol. Sci., USC, Los Angeles, CA

Abstract: Among the unresolved challenges - ancient and modern - faced by the neuroanatomy and connectomics communities, none are more fundamental than the systematic description and unambiguous communication of findings. Without these, no effective mass-scale integration of anatomical and connectional data can be achieved. The accelerating volume of novel neuroanatomical data generated worldwide vastly outpaces the rate at which it is curated into analytic frameworks to synthesize systems-level understanding of the nervous system. To help address these challenges, we propose the Neural Systems Language, NSyL. NSyL is a modeling language for systematically representing and communicating neural connectivity. NSyL may be

used irrespective of the animal taxon described, experimental or observational technique implemented, anatomical nomenclature referenced, or computer system used for storage and analysis. NSyL is internally consistent, concise, and readable by both humans and machines. NSyL's power to express connectivity asserted from any connectomic technique in any taxon or species using any nomenclature grants it high utility and flexibility while providing a universal framework for efficient and unambiguous communication between anatomists and experimentalists. Additionally, NSyL's machine-readable nature takes advantage of cutting-edge technology and automation to help bridge the biocuration gap between the producers and consumers of connectomic information. Here we present precedent like-systems, how NSyL synergizes with existing frameworks, the reasoning behind NSyL's development as a language and framework, how NSyL is to be used, and NSyLs potential impact in neuroanatomy, neuroinformatics, and systems neuroscience. NSyL is an intuitive yet nonetheless breakthrough step forward for both systematizing discourse of neural circuitry and streamlining the cycle of scientific inquiry.

Title: Analyzing clinical and genetic data of alzheimer's disease in a colombian population

Authors: *H. A. GRANADOS, Y. GUZMAN, J. ORTEGA, L. MORALES, L. SEGURA, L. LOPÉZ, A. MEJIA, D. FORERO, R. PARDO, J. YUNIS, G. ARBOLEDA, L. NIÑO UNIVERSIDAD NACIONAL DE COLOMBIA, Bogotá. D.C, Colombia

Abstract: Alzheimer's disease (AD) is a degenerative brain disorder that results in memory loss, difficulty to find the correct words when speaking and changes in personality. The institute of Genetics of the Universidad Nacional de Colombia has been performing association studies about the Alzheimer's disease (AD) in Colombia for about ten years. In this study, socio-demographic and genetic information from a colombian population of 48 controls and 98 AD cases are analyzed. This research aims at identifying genetic and clinical characteristics associated with the presence of the AD. Also, some classifiers based on computational

intelligence techniques to help the diagnosis of AD were designed and implemented. Particularly, some classifiers for the AD disease based on neural networks, support vector machines and Bayesian networks were implemented. A multilayer perceptron obtained a 73.9 % cassification rate, while a Support Vector Machine, using a polynomial kernel, obtained a 78.76 % classification rate. On the other hand, a Bayesian Network with simple estimator and search algorithm TAN obtained a 82.87% classification rate. This research also used the a priori algorithm to identify some association rules related to the diagnosis of AD, thus, some association rules were obtained. Some of such rules are: i) family history of dementia is related to AD diagnosis; ii) diagnosis of patients older than 65 and with a family history of dementia are related to AD; and iii) an individual whose age is in group G2 (older than 65) and with genotype APOE 34 is related to AD.

Title: Towards practical brain-computer interfaces using high frequency steady-state visual evoked potentials

Authors: *A. HATAKEYAMA[1], J. USHIBA[2], S. HONDA[3]
[1]Dept. of Fundamental Sci. and Technol., [2]Dept. of Biosci. and Informatics, [3]Dept. of Applied Physics and Physico-Informatics, Keio Univ., Kanagawa, Japan

Abstract: Patients suffering from severe motor disabilities have difficulties in communicating with external environments. Brain-computer interface (BCI) is known as a technology for providing alternative way of communication for these patients by directly measuring brain activity, independently to their peripheral neuromuscular functions. Steady state visual evoked potential (SSVEP), which is categorized as an evoked electroencephalogram, is one considerable resource for BCI system. SSVEP is induced by flickering light stimuli and is obtained from the scalp over the primary visual cortex. In a standard SSVEP-based BCI system, several stimuli flickering at different frequencies are presented to the subjects simultaneously. By focusing on one of the stimuli, it is observed the increase of SSVEP responses at the corresponding frequency

to the stimulus. In SSVEP-based BCI, flickering frequencies in 5-30 Hz range are mostly used since large amplitude of SSVEP is obtained. However, these perceptible flickering light stimuli easily cause irritation of eyes and stress. Moreover, flicker light with frequency around 8-16 Hz is known as a potential trigger of photogenic seizure . For these reasons, such low flickering frequencies seem not to be adequate for practical SSVEP-based BCI. The present study therefore proposed to use flickering light with frequencies beyond critical fusion frequency (CFF) to overcome these issues. The frequencies beyond CFF is known to evoke insufficient SSVEP responses so that we proposed a measure to increase the amplitude of SSVEP by means of stochastic resonance (SR) by applying noisy flickering light in peripheral vision. Moreover, application of cross spectrum analysis was proposed to detect weak but time-locked component to the flickering light in recorded electroencephalogram, and construct the feature set from the calculated coefficients. Five healthy subjects were participated to the proof-of-concept experiment. In the experiment, the flickering frequencies were set higher than CFF. As a result, averaged accuracy over the subjects was 78.5, 82.2, and 85.5% with normal power spectrum analysis, power spectrum analysis with stochastic resonance, and cross spectrum analysis with stochastic resonance, respectively. In conclusion, our proposed method allows all subjects participating in the study to obtain high accuracy.

Title: Enabling new research and developing methods to improve sharing of electrophysiology data using CRCNS.org

Authors: *J. TEETERS, W. CHRISTOPHER, M. THIELK, F. T. SOMMER
UC Berkeley, Berkeley, CA

Abstract: Progress in neuroscience requires experimentation and the gathering of data, as well as analyzing and modeling of data to test and form hypotheses. Usually, researchers within a laboratory do both of these steps and the data are not publicly available. It would be potentially much more efficient if the data were available because other researchers could then analyze it in new ways that are outside the scope of the original investigation.

The resource CRCNS.org was setup to enable the effective sharing of electrophysiology data between experimentalists and theorists through an online repository that hosts data sets and related documentation. The repository currently has 16 data sets. The data sets have been used for research that would not have been possible if the data were not shared. To date, this has resulted in 11 Journal publications and various conference presentations and posters. We seek now to grow the repository both through individual contributions and by having experts curate collections of data sets in their area of specialization.

In addition to being used for new research projects, the variety of data sets at CRCNS.org is very interesting as a test case to address main challenges of sharing electrophysiology data. The challenges are both cultural and technical. A major cultural challenge is that neuroscience researchers are typically reluctant to share data. To help overcome this reluctance, we are developing mechanisms at CRCNS.org to simplify the contribution process and to reward experimentalists for contributing data. These include: making data sets citable, so contributors can list data sets in their CV and get citations for published data; allowing contributors to specify conditions for usage of the data; setting up an infrastructure to make data contribution easy; and enabling self-supporting online communities, which can reduce the demands on contributors to support data users.

The technical challenges stem from the great heterogeneity of the data and metadata. We are developing methods to store neural data as well as stimuli and other metadata using HDF5 as a storage container. This work builds on other efforts in this area including CARMEN NDF, NEO and Neuroshare. Where possible, metadata will reference standard ontologies such as those being developed by the NeuroLex project. Metadata useful for locating relevant data sets will be provided to the Neuroscience Information Framework for indexing. Both data and stimuli in data sets will be made available for online browsing and for automated tools of machine learning.
